```
Insurance
```

### Format

This data frame contains the following columns:

District factor: district of residence of policyholder (1 to 4): 4 is major cities.

Group an ordered factor: group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.

Age an ordered factor: the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.

Holders numbers of policyholders.

Claims numbers of claims

### Examples

```
main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
 data = Insurance, family = poisson)

same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
 data = Insurance)
```

isoMDS

*Kruskal's Non-metric Multidimensional Scaling***Description**

One form of non-metric multidimensional scaling

**Usage**

```
isoMDS(d, y = cmdscale(d, k), k = 2, maxit = 50, trace = TRUE,
 tol = 1e-3, p = 2)
```

```
Shepard(d, x, p = 2)
```

**Arguments**

|       |                                                                                                                                                                                                                                                        |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d     | distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. Both missing and infinite values are allowed. |
| y     | An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution, unless there are missing or infinite dissimilarities.                                                                                  |
| k     | The desired dimension for the solution, passed to <code>cmdscale</code> .                                                                                                                                                                              |
| maxit | The maximum number of iterations.                                                                                                                                                                                                                      |
| trace | Logical for tracing optimization. Default TRUE.                                                                                                                                                                                                        |
| tol   | convergence tolerance.                                                                                                                                                                                                                                 |
| p     | Power for Minkowski distance in the configuration space.                                                                                                                                                                                               |
| x     | A final configuration.                                                                                                                                                                                                                                 |

**Details**

This chooses a  $k$ -dimensional (default  $k = 2$ ) configuration to minimize the stress, the square root of the ratio of the sum of squared differences between the input distances and those of the configuration to the sum of configuration distances squared. However, the input distances are allowed a monotonic transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is necessarily an  $O(n^2)$  calculation, it is slow for large datasets. Further, since for the default  $p = 2$  the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine.

**Value**

Two components:

|        |                                                   |
|--------|---------------------------------------------------|
| points | A $k$ -column vector of the fitted configuration. |
| stress | The final stress achieved (in percent).           |

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 5 iterations.

kde2d

---

*Two-Dimensional Kernel Density Estimation*

---

## Description

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

## Usage

```
kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))
```

## Arguments

|      |                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x    | x coordinate of data                                                                                                                                                                |
| y    | y coordinate of data                                                                                                                                                                |
| h    | vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see <a href="#">bandwidth.nrd</a> ). A scalar value will be taken to apply to both directions. |
| n    | Number of grid points in each direction. Can be scalar or a length-2 integer vector.                                                                                                |
| lims | The limits of the rectangle covered by the grid as c(xl, xu, yl, yu).                                                                                                               |

## Value

A list of three components.

|      |                                                                                                                |
|------|----------------------------------------------------------------------------------------------------------------|
| x, y | The x and y coordinates of the grid points, vectors of length n.                                               |
| z    | An n[1] by n[2] matrix of the estimated density: rows correspond to the value of x, columns to the value of y. |

 lda

*Linear Discriminant Analysis*

---

## Description

Linear discriminant analysis.

## Usage

```
lda(x, ...)

S3 method for class 'formula'
lda(formula, data, ..., subset, na.action)

Default S3 method:
lda(x, grouping, prior = proportions, tol = 1.0e-4,
 method, CV = FALSE, nu, ...)

S3 method for class 'data.frame'
lda(x, ...)

S3 method for class 'matrix'
lda(x, grouping, ..., subset, na.action)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | A formula of the form <code>groups ~ x1 + x2 + ...</code> . That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.                                                                                                             |
| <code>data</code>      | An optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.                                                                                                                                                      |
| <code>x</code>         | (required if no formula is given as the principal argument.) a matrix or data frame or <code>Matrix</code> containing the explanatory variables.                                                                                                                                        |
| <code>grouping</code>  | (required if no formula principal argument is given.) a factor specifying the class for each observation.                                                                                                                                                                               |
| <code>prior</code>     | the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.                                                                                  |
| <code>tol</code>       | A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than <code>tol^2</code> .                                                                                                             |
| <code>subset</code>    | An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)                                                                                                                                                                  |
| <code>na.action</code> | A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.) |
| <code>method</code>    | "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a <i>t</i> distribution.                                                                                                            |
| <code>CV</code>        | If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.                                                                                                  |
| <code>nu</code>        | degrees of freedom for <code>method = "t"</code> .                                                                                                                                                                                                                                      |
| <code>...</code>       | arguments passed to or from other methods.                                                                                                                                                                                                                                              |

**Details**

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than `tol^2` it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the prior will affect the classification unless over-ridden in `predict.lda`. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

**Value**

If `CV = TRUE` the return value is a list with components `class`, the MAP classification (a factor), and `posterior`, posterior probabilities for the classes.

Otherwise it is an object of class "lda" containing the following components:

|                    |                               |
|--------------------|-------------------------------|
| <code>prior</code> | the prior probabilities used. |
|--------------------|-------------------------------|

|         |                                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| means   | the group means.                                                                                                                                                                   |
| scaling | a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.                                                 |
| svd     | the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics. |
| N       | The number of observations used.                                                                                                                                                   |
| call    | The (matched) function call.                                                                                                                                                       |

### Note

This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but `subset=` and `na.action=`, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using `update()` in the usual way.

ldahist

---

*Histograms or Density Plots of Multiple Groups*

---

### Description

Plot histograms or density plots of data on a single Fisher linear discriminant.

**Usage**

```
ldahist(data, g, nbins = 25, h, x0 = - h/1000, breaks,
 xlim = range(breaks), ymax = 0, width,
 type = c("histogram", "density", "both"),
 sep = (type != "density"),
 col = 5, xlab = deparse(substitute(data)), bty = "n", ...)
```

**Arguments**

|        |                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------|
| data   | vector of data. Missing values (NAs) are allowed and omitted.                                               |
| g      | factor or vector giving groups, of the same length as data.                                                 |
| nbins  | Suggested number of bins to cover the whole range of the data.                                              |
| h      | The bin width (takes precedence over nbins).                                                                |
| x0     | Shift for the bins - the breaks are at $x_0 + h * (\dots, -1, 0, 1, \dots)$                                 |
| breaks | The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).                    |
| xlim   | The limits for the x-axis.                                                                                  |
| ymax   | The upper limit for the y-axis.                                                                             |
| width  | Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately. |
| type   | Type of plot.                                                                                               |
| sep    | Whether there is a separate plot for each group, or one combined plot.                                      |
| col    | The colour number for the bar fill.                                                                         |
| xlab   | label for the plot x-axis. By default, this will be the name of data.                                       |
| bty    | The box type for the plot - defaults to none.                                                               |
| ...    | additional arguments to polygon.                                                                            |

**Side Effects**

Histogram and/or density plots are plotted on the current device.

---

leuk*Survival Times and White Blood Counts for Leukaemia Patients*

---

**Description**

A data frame of data from 33 leukaemia patients.

**Usage**

leuk

**Format**

A data frame with columns:

wbc white blood count.

ag a test result, "present" or "absent".

time survival time in weeks.

**Details**

Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient's white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

**Examples**

```
library(survival)
plot(survfit(Surv(time) ~ ag, data = leuk), lty = 2:3, col = 2:3)

now Cox models
leuk.cox <- coxph(Surv(time) ~ ag + log(wbc), leuk)
summary(leuk.cox)
```

lm.gls

*Fit Linear Models by Generalized Least Squares***Description**

Fit linear models by Generalized Least Squares

**Usage**

```
lm.gls(formula, data, W, subset, na.action, inverse = FALSE,
 method = "qr", model = FALSE, x = FALSE, y = FALSE,
 contrasts = NULL, ...)
```

**Arguments**

|           |                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula expression as for regression models, of the form response ~ predictors. See the documentation of formula for other details. |
| data      | an optional data frame, list or environment in which to interpret the variables occurring in formula.                                 |
| W         | a weight matrix.                                                                                                                      |
| subset    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.           |
| na.action | a function to filter missing data.                                                                                                    |
| inverse   | logical: if true W specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.                      |
| method    | method to be used by <code>lm.fit</code> .                                                                                            |
| model     | should the model frame be returned?                                                                                                   |
| x         | should the design matrix be returned?                                                                                                 |
| y         | should the response be returned?                                                                                                      |
| contrasts | a list of contrasts to be used for some or all of                                                                                     |
| ...       | additional arguments to <code>lm.fit</code> .                                                                                         |

**Details**

The problem is transformed to uncorrelated form and passed to `lm.fit`.

**Value**

An object of class "lm.gls", which is similar to an "lm" object. There is no "weights" component, and only a few "lm" methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

**See Also**

lm.ridge

*Ridge Regression***Description**

Fit a linear model by ridge regression.

**Usage**

```
lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE,
 x = FALSE, y = FALSE, contrasts = NULL, ...)
select(obj)
```

**Arguments**

|           |                                                                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . See the documentation of <code>formula</code> for other details. <code>offset</code> terms are allowed. |
| data      | an optional data frame, list or environment in which to interpret the variables occurring in <code>formula</code> .                                                                                     |
| subset    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.                                                                             |
| na.action | a function to filter missing data.                                                                                                                                                                      |
| lambda    | A scalar or vector of ridge constants.                                                                                                                                                                  |
| model     | should the model frame be returned? Not implemented.                                                                                                                                                    |
| x         | should the design matrix be returned? Not implemented.                                                                                                                                                  |
| y         | should the response be returned? Not implemented.                                                                                                                                                       |
| contrasts | a list of contrasts to be used for some or all of factor terms in the formula. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .                                                |
| ...       | additional arguments to <code>lm.fit</code> .                                                                                                                                                           |
| obj       | an R object, such as an "lm.ridge" fit.                                                                                                                                                                 |

**Details**

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalize an intercept, put in your own constant term and remove the intercept.)

**Value**

A list with components

|        |                                                                                                                                                                        |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| coef   | matrix of coefficients, one row for each value of <code>lambda</code> . Note that these are not on the original scale and are for use by the <code>coef</code> method. |
| scales | scalings used on the X matrix.                                                                                                                                         |
| Inter  | was intercept included?                                                                                                                                                |
| lambda | vector of <code>lambda</code> values                                                                                                                                   |
| ym     | mean of y                                                                                                                                                              |

|      |                                     |
|------|-------------------------------------|
| xm   | column means of x matrix            |
| GCV  | vector of GCV values                |
| kHKB | HKB estimate of the ridge constant. |
| kLW  | L-W estimate of the ridge constant. |

loglm

---

*Fit Log-Linear Models by Iterative Proportional Scaling*

---

## Description

This function provides a front-end to the standard function, `loglin`, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as `glm`.

## Usage

```
loglm(formula, data, subset, na.action, ...)
```

## Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula | <p>A linear model formula specifying the log-linear model.</p> <p>If the left-hand side is empty, the data argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the <code>dimnames</code> attribute of the frequency array, or may be the positive integers: 1, 2, 3, ... used as alternative names for the 1st, 2nd, 3rd, ... dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the data argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a . to stand for 'all other variables in the data frame' is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.</p> |
| data    | <p>Numeric array or data frame (or list or environment). In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way. This argument may be the result of a call to <a href="#">xtabs</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|           |                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------|
| subset    | Specifies a subset of the rows in the data frame to be used. The default is to take all rows.               |
| na.action | Specifies a method for handling missing observations. The default is to fail if missing values are present. |
| ...       | May supply other arguments to the function <a href="#">loglm1</a> .                                         |

### Details

If the left-hand side of the formula is empty the data argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by `loglin`. Structural zeros may be specified by giving a `start` argument with those entries set to zero, as described in the help information for `loglin`.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by `loglin`. Hence terms such as `a:b`, `a*b` and `a/b` are all equivalent.

### Value

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions `print`, `summary`, `deviance`, `fitted`, `coef`, `resid`, `anova` and `update`, which perform the expected tasks. Only log-likelihood ratio tests are allowed using `anova`.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

### Warning

If structural zeros are present, the calculation of degrees of freedom may not be correct. `loglin` itself takes no action to allow for structural zeros. `loglm` deducts one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

### Examples

```
The data frames Cars93, minn38 and quine are available
in the MASS package.

Case 1: frequencies specified as an array.
sapply(minn38, function(x) length(levels(x)))
hs phs fol sex f
```

```
3 4 7 2 0
##minn38a <- array(0, c(3,4,7,2), lapply(minn38[, -5], levels))
##minn38a[data.matrix(minn38[, -5])] <- minn38$f

or more simply
minn38a <- xtabs(f ~ ., minn38)

fm <- loglm(~ 1 + 2 + 3 + 4, minn38a) # numerals as names.
deviance(fm)
[1] 3711.9
fm1 <- update(fm, .~.^2)
fm2 <- update(fm, .~.^3, print = TRUE)
5 iterations: deviation 0.075
anova(fm, fm1, fm2)

Case 1. An array generated with xtabs.

loglm(~ Type + Origin, xtabs(~ Type + Origin, Cars93))

Case 2. Frequencies given as a vector in a data frame
names(quine)
[1] "Eth" "Sex" "Age" "Lrn" "Days"
fm <- loglm(Days ~ .^2, quine)
gm <- glm(Days ~ .^2, poisson, quine) # check glm.
c(deviance(fm), deviance(gm)) # deviances agree
[1] 1368.7 1368.7
c(fmdf, gmdf) # resid df do not!
c(fmdf, gmdf.residual) # resid df do not!
[1] 127 128
The loglm residual degrees of freedom is wrong because of
a non-detectable redundancy in the model matrix.
```

---

logtrans

---

*Estimate log Transformation Parameter*

---

## Description

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form  $\log(y + \alpha) \sim x_1 + x_2 + \dots$

## Usage

```
logtrans(object, ...)

Default S3 method:
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y),
 plotit = TRUE, interp =, xlab = "alpha",
 ylab = "log Likelihood")

S3 method for class 'formula'
logtrans(object, data, ...)

S3 method for class 'lm'
logtrans(object, ...)
```

Arguments

|        |                                                                                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | Fitted linear model object, or formula defining the untransformed model that is $y \sim x_1 + x_2 + \dots$ . The function is generic.                                       |
| ...    | If object is a formula, this argument may specify a data frame as for <code>lm</code> .                                                                                     |
| alpha  | Set of values for the transformation parameter, alpha.                                                                                                                      |
| plotit | Should plotting be done?                                                                                                                                                    |
| interp | Should the marginal log-likelihood be interpolated with a spline approximation? (Default is TRUE if plotting is to be done and the number of real points is less than 100.) |
| xlab   | as for <code>plot</code> .                                                                                                                                                  |
| ylab   | as for <code>plot</code> .                                                                                                                                                  |
| data   | optional data argument for <code>lm</code> fit.                                                                                                                             |

Value

List with components `x` (for alpha) and `y` (for the marginal log-likelihood values).

Side Effects

A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

|     |                             |
|-----|-----------------------------|
| lqs | <i>Resistant Regression</i> |
|-----|-----------------------------|

---

Description

Fit a regression to the *good* points in the dataset, thereby achieving a regression estimator with a high breakdown point. `lmsreg` and `ltsreg` are compatibility wrappers.

**Usage**

```

lqs(x, ...)

S3 method for class 'formula'
lqs(formula, data, ...,
 method = c("lts", "lqs", "lms", "S", "model.frame"),
 subset, na.action, model = TRUE,
 x.ret = FALSE, y.ret = FALSE, contrasts = NULL)

Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),
 quantile, control = lqs.control(...), k0 = 1.548, seed, ...)

lmsreg(...)
ltsreg(...)

```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula             | a formula of the form $y \sim x_1 + x_2 + \dots$                                                                                                                                                                                                                                                                                 |
| data                | an optional data frame, list or environment from which variables specified in formula are preferentially to be taken.                                                                                                                                                                                                            |
| subset              | an index vector specifying the cases to be used in fitting. (NOTE: If given, this argument must be named exactly.)                                                                                                                                                                                                               |
| na.action           | function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. Alternatives include <a href="#">na.omit</a> and <a href="#">na.exclude</a> , which lead to omission of cases with missing values on any required variable. (NOTE: If given, this argument must be named exactly.) |
| model, x.ret, y.ret | logical. If TRUE the model frame, the model matrix and the response are returned, respectively.                                                                                                                                                                                                                                  |
| contrasts           | an optional list. See the contrasts.arg of <a href="#">model.matrix.default</a> .                                                                                                                                                                                                                                                |
| x                   | a matrix or data frame containing the explanatory variables.                                                                                                                                                                                                                                                                     |
| y                   | the response: a vector of length the number of rows of x.                                                                                                                                                                                                                                                                        |
| intercept           | should the model include an intercept?                                                                                                                                                                                                                                                                                           |
| method              | the method to be used. <code>model.frame</code> returns the model frame: for the others see the Details section. Using <code>lmsreg</code> or <code>ltsreg</code> forces "lms" and "lts" respectively.                                                                                                                           |
| quantile            | the quantile to be used: see Details. This is over-ridden if method = "lms".                                                                                                                                                                                                                                                     |
| control             | additional control items: see Details.                                                                                                                                                                                                                                                                                           |
| k0                  | the cutoff / tuning constant used for $\chi()$ and $\psi()$ functions when method = "S", currently corresponding to Tukey's 'biweight'.                                                                                                                                                                                          |
| seed                | the seed to be used for random sampling: see <code>.Random.seed</code> . | ...                 | arguments to be passed to <code>lqs.default</code> or <code>lqs.control</code> , see control above and Details.                                                                                                                                                                                                                  |

## Details

Suppose there are  $n$  data points and  $p$  regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for quantile, which are  $\text{floor}((n+p+1)/2)$  and  $\text{floor}((n+1)/2)$  respectively. For "lts" the default is  $\text{floor}(n/2) + \text{floor}((p+1)/2)$ .

The "S" estimation method solves for the scale  $s$  such that the average of a function  $\chi$  of the residuals divided by  $s$  is equal to a given constant.

The control argument is a list with components

**psamp:** the size of each sample. Defaults to  $p$ .

**nsamp:** the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is  $\min(5 \cdot p, 3000)$ , taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.

**adjust:** should the intercept be optimized for each sample? Defaults to TRUE.

## Value

An object of class "lqs". This is a list with components

|                      |                                                                                                                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>crit</b>          | the value of the criterion for the best solution found, in the case of method == "S" before IWLS refinement.                                                                                                                             |
| <b>sing</b>          | character. A message about the number of samples which resulted in singular fits.                                                                                                                                                        |
| <b>coefficients</b>  | of the fitted linear model                                                                                                                                                                                                               |
| <b>bestone</b>       | the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).                                                                                                                        |
| <b>fitted.values</b> | the fitted values.                                                                                                                                                                                                                       |
| <b>residuals</b>     | the residuals.                                                                                                                                                                                                                           |
| <b>scale</b>         | estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for method == "S") is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate. |

## Note

There seems no reason other than historical to use the lms and lqs options. LMS estimation is of low efficiency (converging at rate  $n^{-1/3}$ ) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of  $(\text{floor}((n-p)/2) + 1)/n$  attained if  $\text{floor}((n+p)/2) \leq \text{quantile} \leq \text{floor}((n+p+1)/2)$ . The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if  $n$  is large and  $p$  small.

Opinions differ over the choice of psamp. Rousseeuw and Hubert (1997) only consider  $p$ ; Marazzi (1993) recommends  $p+1$  and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

mca

*Multiple Correspondence Analysis***Description**

Computes a multiple correspondence analysis of a set of factors.

**Usage**

```
mca(df, nf = 2, abbrev = FALSE)
```

**Arguments**

|        |                                                                                                                                                                                            |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| df     | A data frame containing only factors                                                                                                                                                       |
| nf     | The number of dimensions for the MCA. Rarely 3 might be useful.                                                                                                                            |
| abbrev | Should the vertex names be abbreviated? By default these are of the form ‘factor.level’ but if abbrev = TRUE they are just ‘level’ which will suffice if the factors have distinct levels. |

**Value**

An object of class "mca", with components

|      |                                                                                            |
|------|--------------------------------------------------------------------------------------------|
| rs   | The coordinates of the rows, in nf dimensions.                                             |
| cs   | The coordinates of the column vertices, one for each level of each factor.                 |
| fs   | Weights for each row, used to interpolate additional factors in <code>predict.mca</code> . |
| p    | The number of factors                                                                      |
| d    | The singular values for the nf dimensions.                                                 |
| call | The matched call.                                                                          |

 binomial(link = probit), data = menarche)
```

michelson

*Michelson's Speed of Light Data***Description**

Measurements of the speed of light in air, made between 5th June and 2nd July, 1879. The data consists of five experiments, each consisting of 20 consecutive runs. The response is the speed of light in km/s, less 299000. The currently accepted value, on this scale of measurement, is 734.5.

**Usage**

michelson

**Format**

The data frame contains the following components:

Expt The experiment number, from 1 to 5.

Run The run number within each experiment.

Speed Speed-of-light measurement.

minn38

*Minnesota High School Graduates of 1938***Description**

The Minnesota high school graduates of 1938 were classified according to four factors, described below. The minn38 data frame has 168 rows and 5 columns.

**Usage**

minn38

**Format**

This data frame contains the following columns:

hs high school rank: "L", "M" and "U" for lower, middle and upper third.

phs post high school status: Enrolled in college, ("C"), enrolled in non-collegiate school, ("N"), employed full-time, ("E") and other, ("O").

fo1 father's occupational level, (seven levels, "F1", "F2", ..., "F7").

sex sex: factor with levels "F" or "M".

f frequency.

motors

*Accelerated Life Testing of Motorettes*

---

### Description

The motors data frame has 40 rows and 3 columns. It describes an accelerated life test at each of four temperatures of 10 motorettes, and has rather discrete times.

### Usage

motors

### Format

This data frame contains the following columns:

temp the temperature (degrees C) of the test.

time the time in hours to failure or censoring at 8064 hours (= 336 days).

cens an indicator variable for death.

```

muscle

*Effect of Calcium Chloride on Muscle Contraction in Rat Hearts*

## Description

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

## Usage

muscle

## Format

This data frame contains the following columns:

Strip which heart muscle strip was used?

Conc concentration of calcium chloride solution, in multiples of 2.2 mM.

Length the change in length (shortening) of the strip, (allegedly) in mm.

*Simulate from a Multivariate Normal Distribution*

## Description

Produces one or more samples from the specified multivariate normal distribution.

## Usage

```
mvnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE, EISPACK = FALSE)
```

## Arguments

|           |                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------|
| n         | the number of samples required.                                                                 |
| mu        | a vector giving the means of the variables.                                                     |
| Sigma     | a positive-definite symmetric matrix specifying the covariance matrix of the variables.         |
| tol       | tolerance (relative to largest variance) for numerical lack of positive-definiteness in Sigma.  |
| empirical | logical. If true, mu and Sigma specify the empirical not population mean and covariance matrix. |
| EISPACK   | logical: values other than FALSE are an error.                                                  |

## Details

The matrix decomposition is done via eigen; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

## Value

If n = 1 a vector of the same length as mu, otherwise an n by length(mu) matrix with one sample in each row.

**Side Effects**

Causes creation of the dataset `.Random.seed` if it does not already exist, otherwise its value is updated.

|                   |                                                   |
|-------------------|---------------------------------------------------|
| negative.binomial | <i>Family function for Negative Binomial GLMs</i> |
|-------------------|---------------------------------------------------|

---

**Description**

Specifies the information required to fit a Negative Binomial generalized linear model, with known theta parameter, using `glm()`.

**Usage**

```
negative.binomial(theta = stop("'theta' must be specified"), link = "log")
```

**Arguments**

|       |                                                                                                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| theta | The known value of the additional parameter, theta.                                                                                                                         |
| link  | The link function, as a character string, name or one-element character vector specifying one of log, sqrt or identity, or an object of class " <a href="#">link-glm</a> ". |

**Value**

An object of class "family", a list of functions and expressions needed by `glm()` to fit a Negative Binomial generalized linear model.

---

newcomb

*Newcomb's Measurements of the Passage Time of Light*

---

## Description

A numeric vector giving the ‘Third Series’ of measurements of the passage time of light recorded by Newcomb in 1882. The given values divided by 1000 plus 24.8 give the time in millionths of a second for light to traverse a known distance. The ‘true’ value is now considered to be 33.02.

The dataset is given in the order in Staudte and Sheather. Stigler (1977, Table 5) gives the dataset as

```
28 26 33 24 34 -44 27 16 40 -2 29 22 24 21 25 30 23 29 31 19
24 20 36 32 36 28 25 21 28 29 37 25 28 26 30 32 36 26 30 22
36 23 27 27 28 27 31 27 26 33 26 32 32 24 39 28 24 25 32 25
29 27 28 29 16 23
```

However, order is not relevant to its use as an example of robust estimation. (Thanks to Anthony Unwin for bringing this difference to our attention.)

## Usage

nlschools

*Eighth-Grade Pupils in the Netherlands*

---

## Description

Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

## Usage

```
nlschools
```

**Format**

This data frame contains 2287 rows and the following columns:

lang language test score.

IQ verbal IQ.

class class ID.

GS class size: number of eighth-grade pupils recorded in the class (there may be others: see COMB, and some may have been omitted with missing values).

SES social-economic status of pupil's family.

COMB were the pupils taught in a multi-grade class (0/1)? Classes which contained pupils from grades 7 and 8 are coded 1, but only eighth-graders were tested.

npk

---

*Classical N, P, K Factorial Experiment*

---

**Description**

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

**Usage**

```
npk
```

**Format**

The npk data frame has 24 rows and 5 columns:

block which block (label 1 to 6).

N indicator (0/1) for the application of nitrogen.

P indicator (0/1) for the application of phosphate.

K indicator (0/1) for the application of potassium.

yield Yield of peas, in pounds/plot (the plots were (1/70) acre).

**Note**

This dataset is also contained in R 3.0.2 and later.

**Source**

Imperial College, London, M.Sc. exercise sheet.

**References**

|------|--------------------------------|
| Null | <i>Null Spaces of Matrices</i> |
|------|--------------------------------|

---

**Description**

Given a matrix, M, find a matrix N giving a basis for the (left) null space. That is  $\text{crossprod}(N, M) = \text{t}(N) \%*\% M$  is an all-zero matrix and N has the maximum number of linearly independent columns.

**Usage**

```
Null(M)
```

**Arguments**

M Input matrix. A vector is coerced to a 1-column matrix.

**Details**

For a basis for the (right) null space  $\{x : Mx = 0\}$ , use `Null(t(M))`.

**Value**

The matrix N with the basis for the (left) null space, or a matrix with zero columns if the matrix M is square and of maximal rank.

```

oats

*Data from an Oats Field Trial*

## Description

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

## Usage

oats

## Format

This data frame contains the following columns:

B Blocks, levels I, II, III, IV, V and VI.

V Varieties, 3 levels.

N Nitrogen (manurial) treatment, levels 0.0cwt, 0.2cwt, 0.4cwt and 0.6cwt, showing the application in cwt/acre.

Y Yields in 1/4lbs per sub-plot, each of area 1/80 acre.

|     |                                                          |
|-----|----------------------------------------------------------|
| OME | <i>Tests of Auditory Perception in Children with OME</i> |
|-----|----------------------------------------------------------|

---

**Description**

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

**Usage**

OME

**Format**

- The OME data frame has 1129 rows and 7 columns:
- ID Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.
- OME "low" or "high" or "N/A" (at ages other than 30 and 60 months).
- Age Age of the subject (months).
- Loud Loudness of stimulus, in decibels.
- Noise Whether the signal in the stimulus was "coherent" or "incoherent".
- Correct Number of correct responses from Trials trials.
- Trials Number of trials performed.

**Background**

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term 'binaural hearing' is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of

severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

End(Not run)

```

**Description**

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

**Usage**

painters

**Format**

The row names of the data frame are the painters. The components are:

Composition Composition score.

Drawing Drawing score.

Colour Colour score.

Expression Expression score.

School The school to which a painter belongs, as indicated by a factor level code as follows: "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F": Sixteenth Century; "G": Seventeenth Century; "H": French.

---

pairs.lda

---

*Produce Pairwise Scatterplots from an 'lda' Fit*

---

**Description**

Pairwise scatterplot of the data on the linear discriminants.

**Usage**

```
S3 method for class 'lda'
pairs(x, labels = colnames(x), panel = panel.llda,
 dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))
```

**Arguments**

|        |                                                                                                                                                    |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | Object of class "lda".                                                                                                                             |
| labels | vector of character strings for labelling the variables.                                                                                           |
| panel  | panel function to plot the data in each panel.                                                                                                     |
| dimen  | The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used.                  |
| abbrev | whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.                               |
| ...    | additional arguments for pairs.default.                                                                                                            |
| cex    | graphics parameter cex for labels on plots.                                                                                                        |
| type   | type of plot. The default is in the style of <a href="#">pairs.default</a> ; the style "trellis" uses the Trellis function <a href="#">splom</a> . |

**Details**

This function is a method for the generic function `pairs()` for class "lda". It can be invoked by calling `pairs(x)` for an object x of the appropriate class, or directly by calling `pairs.lda(x)` regardless of the class of the object.

**Description**

Parallel coordinates plot

**Usage**

```
parcoord(x, col = 1, lty = 1, var.label = FALSE, ...)
```

**Arguments**

|           |                                                                                     |
|-----------|-------------------------------------------------------------------------------------|
| x         | a matrix or data frame who columns represent variables. Missing values are allowed. |
| col       | A vector of colours, recycled as necessary for each observation.                    |
| lty       | A vector of line types, recycled as necessary for each observation.                 |
| var.label | If TRUE, each variable's axis is labelled with maximum and minimum values.          |
| ...       | Further graphics parameters which are passed to <code>matplot</code> .              |

**Side Effects**

a parallel coordinates plots is drawn.

**Author(s)**

B. D. Ripley. Enhancements based on ideas and code by Fabian Scheipl.

**Examples**

```
parcoord(state.x77[, c(7, 4, 6, 2, 5, 3)])

ir <- rbind(iris3[,1], iris3[,2], iris3[,3])
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0:149)%/%50)
```

---

petrol

---

*N. L. Prater's Petrol Refinery Data*

---

**Description**

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.

These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

**Usage**

```
petrol
```

**Format**

The variables are as follows

No crude oil sample identification label. (Factor.)

SG specific gravity, degrees API. (Constant within sample.)

VP vapour pressure in pounds per square inch. (Constant within sample.)

V10 volatility of crude; ASTM 10% point. (Constant within sample.)

EP desired volatility of gasoline. (The end point. Varies within sample.)

Y yield as a percentage of crude.

**Source**

N. H. Prater (1956) Estimate gasoline yields from crudes. *Petroleum Refiner* **35**, 236–238.

This dataset is also given in D. J. Hand, F. Daly, K. McConway, D. Lunn and E. Ostrowski (eds) (1994) *A Handbook of Small Data Sets*. Chapman & Hall.

## Examples

```
library(nlme)
Petrol <- petrol
Petrol[, 2:5] <- scale(as.matrix(Petrol[, 2:5]), scale = FALSE)
pet3.lme <- lme(Y ~ SG + VP + V10 + EP,
 random = ~ 1 | No, data = Petrol)
pet3.lme <- update(pet3.lme, method = "ML")
pet4.lme <- update(pet3.lme, fixed. = Y ~ V10 + EP)
anova(pet4.lme, pet3.lme)
```

---

Pima.tr

*Diabetes in Pima Indian Women*

---

## Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

## Usage

```
Pima.tr
Pima.tr2
Pima.te
```

## Format

These data frames contains the following columns:

npreg number of pregnancies.  
glu plasma glucose concentration in an oral glucose tolerance test.  
bp diastolic blood pressure (mm Hg).  
skin triceps skin fold thickness (mm).  
bmi body mass index (weight in kg/(height in m)<sup>2</sup>).  
ped diabetes pedigree function.  
age age in years.  
type Yes or No, for diabetic according to WHO criteria.

## Details

The training set Pima.tr contains a randomly selected set of 200 subjects, and Pima.te contains the remaining 332 subjects. Pima.tr2 contains Pima.tr plus 100 subjects with missing values in the explanatory variables.

|----------|------------------------------------|
| plot.lda | <i>Plot Method for Class 'lda'</i> |
|----------|------------------------------------|

---

## Description

Plots a set of data on one, two or more linear discriminants.

## Usage

```
S3 method for class 'lda'
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,
 abbrev = FALSE, xlab = "LD1", ylab = "LD2")
```

## Arguments

|        |                                                                                                                                   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------|
| x      | An object of class "lda".                                                                                                         |
| panel  | the panel function used to plot the data.                                                                                         |
| ...    | additional arguments to pairs, ldahist or eqscplot.                                                                               |
| cex    | graphics parameter cex for labels on plots.                                                                                       |
| dimen  | The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used. |
| abbrev | whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.              |
| xlab   | label for the x axis                                                                                                              |
| ylab   | label for the y axis                                                                                                              |

## Details

This function is a method for the generic function plot() for class "lda". It can be invoked by calling plot(x) for an object x of the appropriate class, or directly by calling plot.lda(x) regardless of the class of the object.

The behaviour is determined by the value of dimen. For dimen > 2, a pairs plot is used. For dimen = 2, an equiscaled scatter plot is drawn. For dimen = 1, a set of histograms or density plots are drawn. Use argument type to match "histogram" or "density" or "both".

plot.mca

*Plot Method for Objects of Class 'mca'***Description**

Plot a multiple correspondence analysis.

**Usage**

```
S3 method for class 'mca'
plot(x, rows = TRUE, col, cex = par("cex"), ...)
```

**Arguments**

|          |                                                                                      |
|----------|--------------------------------------------------------------------------------------|
| x        | An object of class "mca".                                                            |
| rows     | Should the coordinates for the rows be plotted, or just the vertices for the levels? |
| col, cex | The colours and cex to be used for the row points and level vertices respectively.   |
| ...      | Additional parameters to plot.                                                       |

plot(mca(farms, abbrev = TRUE))
```

polr

*Ordered Logistic or Probit Regression***Description**

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is *proportional odds logistic regression*, after which the function is named.

**Usage**

```
polr(formula, data, weights, start, ..., subset, na.action,
 contrasts = NULL, Hess = FALSE, model = TRUE,
 method = c("logistic", "probit", "loglog", "cloglog", "cauchit"))
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. The model must have an intercept: attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of <a href="#">formula</a> for other details. |
| <code>data</code>      | an optional data frame, list or environment in which to interpret the variables occurring in <code>formula</code> .                                                                                                                                                                                                                                                                                                                                |
| <code>weights</code>   | optional case weights in fitting. Default to 1.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>start</code>     | initial values for the parameters. This is in the format <code>c(coefficients, zeta)</code> : see the Values section.                                                                                                                                                                                                                                                                                                                              |
| <code>...</code>       | additional arguments to be passed to <a href="#">optim</a> , most often a control argument.                                                                                                                                                                                                                                                                                                                                                        |
| <code>subset</code>    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.                                                                                                                                                                                                                                                                                                                        |
| <code>na.action</code> | a function to filter missing data.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>contrasts</code> | a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.                                                                                                                                                                                                                                                                                                                                         |
| <code>Hess</code>      | logical for whether the Hessian (the observed information matrix) should be returned. Use this if you intend to call <code>summary</code> or <code>vcov</code> on the fit.                                                                                                                                                                                                                                                                         |
| <code>model</code>     | logical for whether the model matrix should be returned.                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>method</code>    | logistic or probit or (complementary) log-log or cauchit (corresponding to a Cauchy latent variable).                                                                                                                                                                                                                                                                                                                                              |

## Details

This model is what Agresti (2002) calls a *cumulative link* model. The basic interpretation is as a *coarsened* version of a latent variable  $Y_i$  which has a logistic or normal or extreme-value or Cauchy distribution with scale parameter one and a linear model for the mean. The ordered factor which is observed is which bin  $Y_i$  falls into with breakpoints

$$\zeta_0 = -\infty < \zeta_1 < \dots < \zeta_K = \infty$$

This leads to the model

$$\text{logit}P(Y \leq k|x) = \zeta_k - \eta$$

with *logit* replaced by *probit* for a normal latent variable, and  $\eta$  being the linear predictor, a linear function of the explanatory variables (with no intercept). Note that it is quite common for other software to use the opposite sign for  $\eta$  (and hence the coefficients `beta`).

In the logistic case, the left-hand side of the last display is the log odds of category  $k$  or less, and since these are log odds which differ only by a constant for different  $k$ , the odds are proportional. Hence the term *proportional odds logistic regression*.

The log-log and complementary log-log links are the increasing functions  $F^{-1}(p) = -\log(-\log(p))$  and  $F^{-1}(p) = \log(-\log(1 - p))$ ; some call the first the ‘negative log-log’ link. These correspond to a latent variable with the extreme-value distribution for the maximum and minimum respectively.

A *proportional hazards* model for grouped survival times can be obtained by using the complementary log-log link with grouping ordered by increasing times.

[predict](#), [summary](#), [vcov](#), [anova](#), [model.frame](#) and an `extractAIC` method for use with [stepAIC](#) (and [step](#)). There are also [profile](#) and [confint](#) methods.

**Value**

A object of class "polr". This has components

|               |                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| coefficients  | the coefficients of the linear predictor, which has no intercept.                                                    |
| zeta          | the intercepts for the class boundaries.                                                                             |
| deviance      | the residual deviance.                                                                                               |
| fitted.values | a matrix, with a column for each level of the response.                                                              |
| lev           | the names of the response levels.                                                                                    |
| terms         | the terms structure describing the model.                                                                            |
| df.residual   | the number of residual degrees of freedoms, calculated using the weights.                                            |
| edf           | the (effective) number of degrees of freedom used by the model                                                       |
| n, nobs       | the (effective) number of observations, calculated using the weights. (nobs is for use by <a href="#">stepAIC</a> ). |
| call          | the matched call.                                                                                                    |
| method        | the matched method used.                                                                                             |
| convergence   | the convergence code returned by optim.                                                                              |
| niter         | the number of function and gradient evaluations used by optim.                                                       |
| lp            | the linear predictor (including any offset).                                                                         |
| Hessian       | (if Hess is true). Note that this is a numerical approximation derived from the optimization proces.                 |
| model         | (if model is true).                                                                                                  |

**Note**

The [vcov](#) method uses the approximate Hessian: for reliable results the model matrix should be sensibly scaled with all columns having range the order of one.

Prior to version 7.3-32, method = "cloglog" confusingly gave the log-log link, implicitly assuming the first response level was the 'best'.

predict.glmmPQL

*Predict Method for glmmPQL Fits***Description**

Obtains predictions from a fitted generalized linear model with random effects.

**Usage**

```
S3 method for class 'glmmPQL'
predict(object, newdata = NULL, type = c("link", "response"),
 level, na.action = na.pass, ...)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | a fitted object of class inheriting from "glmmPQL".                                                                                                                                                                                                                                                                           |
| newdata   | optionally, a data frame in which to look for variables with which to predict.                                                                                                                                                                                                                                                |
| type      | the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities. |
| level     | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.                                          |
| na.action | function determining what should be done with missing values in newdata. The default is to predict NA.                                                                                                                                                                                                                        |
| ...       | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                            |

**Value**

If level is a single integer, a vector otherwise a data frame.

**See Also**

[glmmPQL](#), [predict.lme](#).

**Examples**

```
fit <- glmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
 family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```

predict.lda

*Classify Multivariate Observations by Linear Discrimination***Description**

Classify multivariate observations in conjunction with `lda`, and also project data onto the linear discriminants.

**Usage**

```
S3 method for class 'lda'
predict(object, newdata, prior = object$prior, dimen,
 method = c("plug-in", "predictive", "debiased"), ...)
```

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | object of class "lda"                                                                                                                                                                                                                                                                                                                    |
| <code>newdata</code> | data frame of cases to be classified or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>lda</code> object.                |
| <code>prior</code>   | The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to <code>lda</code> .                                                                                                                                                                                                 |
| <code>dimen</code>   | the dimension of the space to be used. If this is less than $\min(p, n-1)$ , only the first <code>dimen</code> discriminant components are used (except for <code>method="predictive"</code> ), and only those dimensions are returned in <code>x</code> .                                                                               |
| <code>method</code>  | This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. |
| <code>...</code>     | arguments based from or to other methods                                                                                                                                                                                                                                                                                                 |

**Details**

This function is a method for the generic function `predict()` for class "lda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning NA if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by prior) of the group centroids is at the origin.

**Value**

a list with components

|           |                                                                             |
|-----------|-----------------------------------------------------------------------------|
| class     | The MAP classification (a factor)                                           |
| posterior | posterior probabilities for the classes                                     |
| x         | the scores of test cases on up to <code>dimen</code> discriminant variables |

predict.mca

*Predict Method for Class 'mca'*

---

**Description**

Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

**Usage**

```
S3 method for class 'mca'
predict(object, newdata, type = c("row", "factor"), ...)
```

**Arguments**

|                      |                                                                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | An object of class <code>"mca"</code> , usually the result of a call to <code>mca</code> .                                                                                |
| <code>newdata</code> | A data frame containing <i>either</i> additional rows of the factors used to fit <code>object</code> <i>or</i> additional factors for the cases used in the original fit. |
| <code>type</code>    | Are predictions required for further rows or for new factors?                                                                                                             |
| <code>...</code>     | Additional arguments from <code>predict</code> : unused.                                                                                                                  |

**Value**

If `type = "row"`, the coordinates for the additional rows.

If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.

|-------------|------------------------------------------------------|
| predict.qda | <i>Classify from Quadratic Discriminant Analysis</i> |
|-------------|------------------------------------------------------|

---

Description

Classify multivariate observations in conjunction with qda

Usage

```
S3 method for class 'qda'
predict(object, newdata, prior = object$prior,
 method = c("plug-in", "predictive", "debiased", "looCV"), ...)
```

Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | object of class "qda"                                                                                                                                                                                                                                                                                                                                                                                                                            |
| newdata | data frame of cases to be classified or, if object has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If newdata is missing, an attempt will be made to retrieve the data used to fit the qda object.                                                                                                                                                               |
| prior   | The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to qda.                                                                                                                                                                                                                                                                                                                       |
| method  | This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. With "looCV" the leave-one-out cross-validation fits to the original dataset are computed and returned. |
| ...     | arguments based from or to other methods                                                                                                                                                                                                                                                                                                                                                                                                         |

Details

This function is a method for the generic function `predict()` for class "qda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.qda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning NA if the quadratic discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

**Value**

a list with components

|           |                                         |
|-----------|-----------------------------------------|
| class     | The MAP classification (a factor)       |
| posterior | posterior probabilities for the classes |

tr <- sample(1:50, 25)
train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
zq <- qda(train, cl)
predict(zq, test)$class
```

---

profile.glm

*Method for Profiling glm Objects*

---

**Description**

Investigates the profile log-likelihood function for a fitted model of class "glm".

As from R 4.4.0 was migrated to package **stats** with additional functionality.

---

qda

*Quadratic Discriminant Analysis*

---

**Description**

Quadratic discriminant analysis.

**Usage**

```

qda(x, ...)

S3 method for class 'formula'
qda(formula, data, ..., subset, na.action)

Default S3 method:
qda(x, grouping, prior = proportions,
 method, CV = FALSE, nu, ...)

S3 method for class 'data.frame'
qda(x, ...)

S3 method for class 'matrix'
qda(x, grouping, ..., subset, na.action)

```

**Arguments**

|           |                                                                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | A formula of the form $\text{groups} \sim x_1 + x_2 + \dots$ . That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.                                                                                                          |
| data      | An optional data frame, list or environment from which variables specified in formula are preferentially to be taken.                                                                                                                                                                   |
| x         | (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.                                                                                                                                                     |
| grouping  | (required if no formula principal argument is given.) a factor specifying the class for each observation.                                                                                                                                                                               |
| prior     | the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.                                                                                |
| subset    | An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)                                                                                                                                                                  |
| na.action | A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.) |
| method    | "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a t distribution.                                                                                                                   |
| CV        | If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.                                                                                                  |
| nu        | degrees of freedom for <code>method = "t"</code> .                                                                                                                                                                                                                                      |
| ...       | arguments passed to or from other methods.                                                                                                                                                                                                                                              |

**Details**

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

Value

an object of class "qda" containing the following components:

|         |                                                                                                                                  |
|---------|----------------------------------------------------------------------------------------------------------------------------------|
| prior   | the prior probabilities used.                                                                                                    |
| means   | the group means.                                                                                                                 |
| scaling | for each group i, scaling[, , i] is an array which transforms observations so that within-groups covariance matrix is spherical. |
| ldet    | a vector of half log determinants of the dispersion matrix.                                                                      |
| lev     | the levels of the grouping factor.                                                                                               |
| terms   | (if formula is a formula) an object of mode expression and class term summarizing the formula.                                   |
| call    | the (matched) function call.                                                                                                     |

unless CV=TRUE, when the return value is a list with components:

|           |                                         |
|-----------|-----------------------------------------|
| class     | The MAP classification (a factor)       |
| posterior | posterior probabilities for the classes |

|-------|---------------------------------------------------------|
| quine | <i>Absenteeism from School in Rural New South Wales</i> |
|-------|---------------------------------------------------------|

---

Description

The quine data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

Usage

quine

**Format**

This data frame contains the following columns:

Eth ethnic background: Aboriginal or Not, ("A" or "N").

Sex sex: factor with levels ("F" or "M").

Age age group: Primary ("F0"), or forms "F1", "F2" or "F3".

Lrn learner status: factor with levels Average or Slow learner, ("AL" or "SL").

Days days absent from school in the year.

Rabbit

---

*Blood Pressure in Rabbits*

---

**Description**

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the  $5-HT_3$  antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of  $5-HT_3$  receptors.

**Usage**

Rabbit

**Format**

This data frame contains 60 rows and the following variables:

BPchange change in blood pressure relative to the start of the experiment.

Dose dose of Phenylbiguanide in micrograms.

Run label of run ("C1" to "C5", then "M1" to "M5").

Treatment placebo or the  $5-HT_3$  antagonist MDL 72222.

Animal label of animal used ("R1" to "R5").

---

rational*Rational Approximation*

---

**Description**

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

**Usage**

```
rational(x, cycles = 10, max.denominator = 2000, ...)
```

**Arguments**

|                 |                                                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------|
| x               | Any object of mode numeric. Missing values are now allowed.                                                                    |
| cycles          | The maximum number of steps to be used in the continued fraction approximation process.                                        |
| max.denominator | An early termination criterion. If any partial denominator exceeds max.denominator the continued fraction stops at that point. |
| ...             | arguments passed to or from other methods.                                                                                     |

**Details**

Each component is first expanded in a continued fraction of the form

$$x = \text{floor}(x) + 1/(p_1 + 1/(p_2 + \dots))$$

where  $p_1, p_2, \dots$  are positive integers, terminating either at `cycles` terms or when a  $p_j > \text{max.denominator}$ . The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

**Value**

A numeric object with the same attributes as `x` but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

**See Also**

[fractions](#)

**Examples**

```
X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
rational(solve(X, X/5))
```

---

renumerate

---

*Convert a Formula Transformed by 'denumerate'*

---

### Description

`denumerate` converts a formula written using the conventions of `loglm` into one that `terms` is able to process. `renumerate` converts it back again to a form like the original.

### Usage

```
renumerate(x)
```

### Arguments

`x`                      A formula, normally as modified by `denumerate`.

### Details

This is an inverse function to `denumerate`. It is only needed since `terms` returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

### Value

A formula where all variables with names of the form `.vn`, where `n` is an integer, converted to numbers, `n`, as allowed by the formula conventions of `loglm`.

### See Also

`denumerate`

### Examples

```
denumerate(~(1+2+3)^3 + a/b)
~ (.v1 + .v2 + .v3)^3 + a/b
renumerate(.Last.value)
~ (1 + 2 + 3)^3 + a/b
```

---

rlm

---

*Robust Fitting of Linear Models*

---

### Description

Fit a linear model by robust regression using an M estimator.

**Usage**

```
rlm(x, ...)

S3 method for class 'formula'
rlm(formula, data, weights, ..., subset, na.action,
 method = c("M", "MM", "model.frame"),
 wt.method = c("inv.var", "case"),
 model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
 init = "ls", psi = psi.huber,
 scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
 method = c("M", "MM"), wt.method = c("inv.var", "case"),
 maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.huber(u, k = 1.345, deriv = 0)
psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
psi.bisquare(u, c = 4.685, deriv = 0)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula of the form $y \sim x_1 + x_2 + \dots$                                                                                                                                                                                                                                                                        |
| data      | an optional data frame, list or environment from which variables specified in formula are preferentially to be taken.                                                                                                                                                                                                   |
| weights   | a vector of prior weights for each case.                                                                                                                                                                                                                                                                                |
| subset    | An index vector specifying the cases to be used in fitting.                                                                                                                                                                                                                                                             |
| na.action | A function to specify the action to be taken if NAs are found. The ‘factory-fresh’ default action in R is <a href="#">na.omit</a> , and can be changed by <a href="#">options(na.action=)</a> .                                                                                                                         |
| x         | a matrix or data frame containing the explanatory variables.                                                                                                                                                                                                                                                            |
| y         | the response: a vector of length the number of rows of x.                                                                                                                                                                                                                                                               |
| method    | currently either M-estimation or MM-estimation or (for the formula method only) find the model frame. MM-estimation is M-estimation with Tukey’s bi-weight initialized by a specific S-estimator. See the ‘Details’ section.                                                                                            |
| wt.method | are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable?                                                                                                          |
| model     | should the model frame be returned in the object?                                                                                                                                                                                                                                                                       |
| x.ret     | should the model matrix be returned in the object?                                                                                                                                                                                                                                                                      |
| y.ret     | should the response be returned in the object?                                                                                                                                                                                                                                                                          |
| contrasts | optional contrast specifications: see <a href="#">lm</a> .                                                                                                                                                                                                                                                              |
| w         | (optional) initial down-weighting for each case.                                                                                                                                                                                                                                                                        |
| init      | (optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a coef component. Known methods are “ls” (the default) for an initial least-squares fit using weights $w \times \text{weights}$ , and “lts” for an unweighted least-trimmed squares fit with 200 samples. |
| psi       | the psi function is specified by this argument. It must give (possibly by name) a function $g(x, \dots, \text{deriv})$ that for $\text{deriv}=0$ returns $\psi(x)/x$ and for $\text{deriv}=1$ returns $\psi'(x)$ . Tuning constants will be passed in via $\dots$ .                                                     |

|                          |                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>scale.est</code>   | method of scale estimation: re-scaled MAD of the residuals (default) or Huber's proposal 2 (which can be selected by either "Huber" or "proposal 2"). |
| <code>k2</code>          | tuning constant used for Huber proposal 2 scale estimation.                                                                                           |
| <code>maxit</code>       | the limit on the number of IWLS iterations.                                                                                                           |
| <code>acc</code>         | the accuracy for the stopping criterion.                                                                                                              |
| <code>test.vec</code>    | the stopping criterion is based on changes in this vector.                                                                                            |
| <code>...</code>         | additional arguments to be passed to <code>rlm.default</code> or to the <code>psi</code> function.                                                    |
| <code>lqs.control</code> | An optional list of control values for <a href="#">lqs</a> .                                                                                          |
| <code>u</code>           | numeric vector of evaluation points.                                                                                                                  |
| <code>k, a, b, c</code>  | tuning constants.                                                                                                                                     |
| <code>deriv</code>       | 0 or 1: compute values of the <code>psi</code> function or of its first derivative.                                                                   |

### Details

Fitting is done by iterated re-weighted least squares (IWLS).

Psi functions are supplied for the Huber, Hampel and Tukey bisquare proposals as `psi.huber`, `psi.hampel` and `psi.bisquare`. Huber's corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.

Selecting `method = "MM"` selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with  $k_0 = 1.548$ ; this gives (for  $n \gg p$ ) breakdown point 0.5. The final estimator is an M-estimator with Tukey's biweight and fixed scale that will inherit this breakdown point provided  $c > k_0$ ; this is true for the default value of  $c$  that corresponds to 95% relative efficiency at the normal. Case weights are not supported for `method = "MM"`.

### Value

An object of class `"rlm"` inheriting from `"lm"`. Note that the `df.residual` component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by `"lm"` methods.

The additional components not in an `lm` object are

|                        |                                                                       |
|------------------------|-----------------------------------------------------------------------|
| <code>s</code>         | the robust scale estimate used                                        |
| <code>w</code>         | the weights used in the IWLS process                                  |
| <code>psi</code>       | the <code>psi</code> function with parameters substituted             |
| <code>conv</code>      | the convergence criteria at each iteration                            |
| <code>converged</code> | did the IWLS converge?                                                |
| <code>wresid</code>    | a working residual, weighted for <code>"inv.var"</code> weights only. |

### Note

Prior to version 7.3-52, offset terms in formula were omitted from fitted and predicted values.

---

rms.curv

*Relative Curvature Measures for Non-Linear Regression*

---

## Description

Calculates the root mean square parameter effects and intrinsic relative curvatures,  $c^\theta$  and  $c^t$ , for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253ff

## Usage

```
rms.curv(obj)
```

## Arguments

**obj** Fitted model object of class "nls". The model must be fitted using the default algorithm.

## Details

The method of section 7.3.1 of Bates & Watts is implemented. The function `deriv3` should be used generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model.

A print method, `print.rms.curv`, prints the pc and ic components only, suitably annotated.

If either pc or ic exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

## Value

A list of class `rms.curv` with components `pc` and `ic` for parameter effects and intrinsic relative curvatures multiplied by  $\sqrt{F}$ , `ct` and `ci` for  $c^\theta$  and  $c^t$  (unmultiplied), and `C` the C-array as used in section 7.3.1 of Bates & Watts.

Intrinsic: c^iota x sqrt(F) = 0.092
```

---

rnegbin

---

*Simulate Negative Binomial Variates*

---

## Description

Function to generate random outcomes from a Negative Binomial distribution, with mean  $\mu$  and variance  $\mu + \mu^2/\theta$ .

## Usage

```
rnegbin(n, mu = n, theta = stop("'theta' must be specified"))
```

## Arguments

|       |                                                                                                                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| n     | If a scalar, the number of sample values required. If a vector, <code>length(n)</code> is the number required and <code>n</code> is used as the mean vector if <code>mu</code> is not specified. |
| mu    | The vector of means. Short vectors are recycled.                                                                                                                                                 |
| theta | Vector of values of the <code>theta</code> parameter. Short vectors are recycled.                                                                                                                |

## Details

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike `rnbinom` the index can be arbitrary.

## Value

Vector of random Negative Binomial variate values.

## Side Effects

Changes `.Random.seed` in the usual way.

**Examples**

```
Negative Binomials with means fitted(fm) and theta = 4.5
fm <- glm.nb(Days ~ ., data = quine)
dummy <- rnegbin(fitted(fm), theta = 4.5)
```

|------|------------------------------------------|
| road | <i>Road Accident Deaths in US States</i> |
|------|------------------------------------------|

---

**Description**

A data frame with the annual deaths in road accidents for half the US states.

**Usage**

```
road
```

**Format**

Columns are:

state name.

deaths number of deaths.

drivers number of drivers (in 10,000s).

popden population density in people per square mile.

rural length of rural roads, in 1000s of miles.

temp average daily maximum temperature in January.

fuel fuel consumption in 10,000,000 US gallons per year.

| rotifer | <i>Numbers of Rotifers by Fluid Density</i> |
|---------|---------------------------------------------|

---

**Description**

The data give the numbers of rotifers falling out of suspension for different fluid densities. There are two species, pm *Polyartha major* and kc, *Keratella cochlearis* and for each species the number falling out and the total number are given.

**Usage**

```
rotifer
```

**Format**

density specific density of fluid.

pm.y number falling out for *P. major*.

pm.total total number of *P. major*.

kc.y number falling out for *K. cochlearis*.

kc.tot total number of *K. cochlearis*.

sammon

---

*Sammon's Non-Linear Mapping*

---

**Description**

One form of non-metric multidimensional scaling.

**Usage**

```

sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE,
 magic = 0.2, tol = 1e-4)

```

**Arguments**

|       |                                                                                                                                                                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d     | distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.   |
| y     | An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution. (If there are missing values in <code>d</code> , an initial configuration must be provided.) This must not have duplicates. |
| k     | The dimension of the configuration.                                                                                                                                                                                                         |
| niter | The maximum number of iterations.                                                                                                                                                                                                           |
| trace | Logical for tracing optimization. Default TRUE.                                                                                                                                                                                             |
| magic | initial value of the step size constant in diagonal Newton method.                                                                                                                                                                          |
| tol   | Tolerance for stopping, in units of stress.                                                                                                                                                                                                 |

**Details**

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an  $O(n^2)$  calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (`magic`) to ensure that it always goes downhill.

**Value**

Two components:

|        |                                                  |
|--------|--------------------------------------------------|
| points | A two-column vector of the fitted configuration. |
| stress | The final stress achieved.                       |

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 10 iterations.

snails

*Snail Mortality Data*

---

### Description

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

### Usage

```
snails
```

### Format

The data frame contains the following components:

Species snail species A (1) or B (2).

Exposure exposure in weeks.

Rel.Hum relative humidity (4 levels).

Temp temperature, in degrees Celsius (3 levels).

Deaths number of deaths.

N number of snails exposed.

**Description**

Performs stepwise model selection by AIC.

**Usage**

```
stepAIC(object, scope, scale = 0,
 direction = c("both", "backward", "forward"),
 trace = 1, keep = NULL, steps = 1000, use.start = FALSE,
 k = 2, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object representing a model of an appropriate class. This is used as the initial model in the stepwise search.                                                                                                                           |
| scope  | defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used. |
| scale  | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> and <code>aov</code> models (see <code>extractAIC</code> for details).                                                             |

|           |                                                                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| direction | the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward".                                                                  |
| trace     | if positive, information is printed during the running of stepAIC. Larger values may give more information on the fitting process.                                                                                                                |
| keep      | a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically keep will select a subset of the components of the object and return them. The default is not to keep anything. |
| steps     | the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.                                                                                              |
| use.start | if true the updated fits are done starting at the linear predictor for the currently selected model. This may speed up the iterative calculations for glm (and other fits), but it can also slow them down. <b>Not used</b> in R.                 |
| k         | the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.                                                                                  |
| ...       | any additional arguments to extractAIC. (None are currently used.)                                                                                                                                                                                |

### Details

The set of models searched is determined by the scope argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If scope is a single formula, it specifies the upper component, and the lower model is empty. If scope is missing, the initial model is used as the upper model.

Models specified by scope can be templates to update object as used by `update.formula`.

There is a potential problem in using `glm` fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The `glm` method for `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

Where a conventional deviance exists (e.g. for `lm`, `aov` and `glm` fits) this is quoted in the analysis of variance table: it is the *unscaled* deviance.

### Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

### Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an `na.action` other than `na.fail` is used (as is the default in R). We suggest you remove the missing values first.

---

stormer

---

*The Stormer Viscometer Data*

---

**Description**

The stormer viscometer measures the viscosity of a fluid by measuring the time taken for an inner cylinder in the mechanism to perform a fixed number of revolutions in response to an actuating weight. The viscometer is calibrated by measuring the time taken with varying weights while the mechanism is suspended in fluids of accurately known viscosity. The data comes from such a calibration, and theoretical considerations suggest a nonlinear relationship between time, weight and viscosity, of the form  $\text{Time} = (B1 * \text{Viscosity}) / (\text{Weight} - B2) + E$  where  $B1$  and  $B2$  are unknown parameters to be estimated, and  $E$  is error.

**Usage**

```
stormer
```

**Format**

The data frame contains the following components:

Viscosity viscosity of fluid.

Wt actuating weight.

Time time taken.

**Source**

E. J. Williams (1959) *Regression Analysis*. Wiley.

studres

*Extract Studentized Residuals from a Linear Model*

---

**Description**

The Studentized residuals. Like standardized residuals, these are normalized to unit variance, but the Studentized version is fitted ignoring the current data point. (They are sometimes called jack-knifed residuals).

**Usage**

```
studres(object)
```

**Arguments**

object            any object representing a linear model.

**Value**

The vector of appropriately transformed residuals.

summary.loglm*Summary Method Function for Objects of Class 'loglm'*

---

## Description

Returns a summary list for log-linear models fitted by iterative proportional scaling using loglm.

## Usage

```
S3 method for class 'loglm'
summary(object, fitted = FALSE, ...)
```

## Arguments

|        |                                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------------------------|
| object | a fitted loglm model object.                                                                                               |
| fitted | if TRUE return observed and expected frequencies in the result. Using fitted = TRUE may necessitate re-fitting the object. |
| ...    | arguments to be passed to or from other methods.                                                                           |

## Details

This function is a method for the generic function `summary()` for class "loglm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.loglm(x)` regardless of the class of the object.

## Value

a list is returned for use by `print.summary.loglm`. This has components

|         |                                                                                      |
|---------|--------------------------------------------------------------------------------------|
| formula | the formula used to produce object                                                   |
| tests   | the table of test statistics (likelihood ratio, Pearson) for the fit.                |
| oe      | if fitted = TRUE, an array of the observed and expected frequencies, otherwise NULL. |

summary.negbin

*Summary Method Function for Objects of Class 'negbin'***Description**

Identical to `summary.glm`, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

**Usage**

```
S3 method for class 'negbin'
summary(object, dispersion = 1, correlation = FALSE, ...)
```

**Arguments**

|                          |                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>      | fitted model object of class <code>negbin</code> inheriting from <code>glm</code> and <code>lm</code> . Typically the output of <code>glm.nb</code> . |
| <code>dispersion</code>  | as for <code>summary.glm</code> , with a default of 1.                                                                                                |
| <code>correlation</code> | as for <code>summary.glm</code> .                                                                                                                     |
| <code>...</code>         | arguments passed to or from other methods.                                                                                                            |

**Details**

`summary.glm` is used to produce the majority of the output and supply the result. This function is a method for the generic function `summary()` for class `"negbin"`. It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.negbin(x)` regardless of the class of the object.

**Value**

As for `summary.glm`; the additional lines of output are not included in the resultant object.

**Side Effects**

A summary table is produced as for `summary.glm`, with the additional information described above.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

summary.rlm

*Summary Method for Robust Linear Models***Description**

summary method for objects of class "rlm"

**Usage**

```
S3 method for class 'rlm'
summary(object, method = c("XtX", "XtWX"), correlation = FALSE, ...)
```

**Arguments**

|             |                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object      | the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class <code>rlm</code> , in the sense that the components returned by the <code>rlm</code> function will be available. |
| method      | Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?                                                                                                                                            |
| correlation | logical. Should correlations be computed (and printed)?                                                                                                                                                                           |
| ...         | arguments passed to or from other methods.                                                                                                                                                                                        |

**Details**

This function is a method for the generic function `summary()` for class "rlm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.rlm(x)` regardless of the class of the object.

**Value**

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the summary function.

|              |                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| correlation  | The computed correlation coefficient matrix for the coefficients in the model.                                                                                            |
| cov.unscaled | The unscaled covariance matrix; i.e, a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients. |
| sigma        | The scale estimate.                                                                                                                                                       |
| stddev       | A scale estimate used for the standard errors.                                                                                                                            |
| df           | The number of degrees of freedom for the model and for residuals.                                                                                                         |
| coefficients | A matrix with three columns, containing the coefficients, their standard errors and the corresponding t statistic.                                                        |
| terms        | The terms object used in fitting this model.                                                                                                                              |

Description

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

Usage

```
survey
```

Format

- The components of the data frame are:
- Sex The sex of the student. (Factor with levels "Male" and "Female".)
  - Wr.Hnd span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.
  - NW.Hnd span of non-writing hand.
  - W.Hnd writing hand of student. (Factor, with levels "Left" and "Right".)
  - Fold "Fold your arms! Which is on top" (Factor, with levels "R on L", "L on R", "Neither".)
  - Pulse pulse rate of student (beats per minute).
  - Clap "Clap your hands! Which hand is on top?" (Factor, with levels "Right", "Left", "Neither".)
  - Exer how often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None".)
  - Smoke how much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never".)
  - Height height of the student in centimetres.
  - M.I whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial".)
  - Age age of the student in years.

synth.tr

*Synthetic Classification Problem***Description**

The synth.tr data frame has 250 rows and 3 columns. The synth.te data frame has 100 rows and 3 columns. It is intended that synth.tr be used from training and synth.te for testing.

**Usage**

```
synth.tr
synth.te
```

**Format**

These data frames contains the following columns:

```
xs x-coordinate
ys y-coordinate
yc class, coded as 0 or 1.
```

**Source**

Ripley, B.D. (1994) Neural networks and related methods for classification (with discussion). *Journal of the Royal Statistical Society series B* **56**, 409–456.

Ripley, B.D. (1996) *Pattern Recognition and Neural Networks*. Cambridge: Cambridge University Press.

theta.md

*Estimate theta of the Negative Binomial***Description**

Given the estimated mean vector, estimate theta of the Negative Binomial Distribution.

**Usage**

```
theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)

theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25,
 trace = FALSE)

theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)
```

**Arguments**

|         |                                                                                                                                              |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------|
| y       | Vector of observed values from the Negative Binomial.                                                                                        |
| mu      | Estimated mean vector.                                                                                                                       |
| n       | Number of data points (defaults to the sum of weights)                                                                                       |
| dfr     | Residual degrees of freedom (assuming theta known). For a weighted fit this is the sum of the weights minus the number of fitted parameters. |
| weights | Case weights. If missing, taken as 1.                                                                                                        |
| limit   | Limit on the number of iterations.                                                                                                           |
| eps     | Tolerance to determine convergence.                                                                                                          |
| trace   | logical: should iteration progress be printed?                                                                                               |

**Details**

theta.md estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.

theta.ml uses maximum likelihood.

theta.mm calculates the moment estimator of theta by equating the Pearson chi-square  $\sum (y - \mu)^2 / (\mu + \mu^2 / \theta)$  to the residual degrees of freedom.

**Value**

The required estimate of theta, as a scalar. For theta.ml, the standard error is given as attribute "SE".

**See Also**

[glm.nb](#)

**Examples**

```
quine.nb <- glm.nb(Days ~ .^2, data = quine)
theta.md(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))
theta.ml(quine$Days, fitted(quine.nb))
theta.mm(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))

weighted example
yeast <- data.frame(cbind(numbers = 0:5, fr = c(213, 128, 37, 18, 3, 1)))
fit <- glm.nb(numbers ~ 1, weights = fr, data = yeast)
summary(fit)
mu <- fitted(fit)
theta.md(yeast$numbers, mu, dfr = 399, weights = yeast$fr)
theta.ml(yeast$numbers, mu, limit = 15, weights = yeast$fr)
theta.mm(yeast$numbers, mu, dfr = 399, weights = yeast$fr)
```

topo

*Spatial Topographic Data***Description**

The topo data frame has 52 rows and 3 columns, of topographic heights within a 310 feet square.

**Usage**

```
topo
```

**Format**

This data frame contains the following columns:

x x coordinates (units of 50 feet)

y y coordinates (units of 50 feet)

z heights (feet)

Traffic

*Effect of Swedish Speed Limits on Accidents***Description**

An experiment was performed in Sweden in 1961–2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day *j* in 1962 was comparable to day *j* in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

**Usage**

```
Traffic
```

**Format**

This data frame contains the following columns:

year 1961 or 1962.

day of year.

limit was there a speed limit?

y traffic accident count for that day.

|----------|-------------------------|
| truehist | <i>Plot a Histogram</i> |
|----------|-------------------------|

---

## Description

Creates a histogram on the current graphics device.

## Usage

```
truehist(data, nbins = "Scott", h, x0 = -h/1000,
 breaks, prob = TRUE, xlim = range(breaks),
 ymax = max(est), col = "cyan",
 xlab = deparse(substitute(data)), bty = "n", ...)
```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data   | numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.                                                                                                                                                                                                                                                                                        |
| nbins  | The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman-Diaconis" or "FD". (Case is ignored.)                                                                                                                                                                                                                   |
| h      | The bin width, a strictly positive number (takes precedence over nbins).                                                                                                                                                                                                                                                                                                   |
| x0     | Shift for the bins - the breaks are at $x0 + h * (\dots, -1, 0, 1, \dots)$                                                                                                                                                                                                                                                                                                 |
| breaks | The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).                                                                                                                                                                                                                                                                                   |
| prob   | If true (the default) plot a true histogram. The vertical axis has a <i>relative frequency density</i> scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins. |
| xlim   | The limits for the x-axis.                                                                                                                                                                                                                                                                                                                                                 |
| ymax   | The upper limit for the y-axis.                                                                                                                                                                                                                                                                                                                                            |
| col    | The colour for the bar fill: the default is colour 5 in the default R palette.                                                                                                                                                                                                                                                                                             |
| xlab   | label for the plot x-axis. By default, this will be the name of data.                                                                                                                                                                                                                                                                                                      |
| bty    | The box type for the plot - defaults to none.                                                                                                                                                                                                                                                                                                                              |
| ...    | additional arguments to <a href="#">rect</a> or <a href="#">plot</a> .                                                                                                                                                                                                                                                                                                     |

**Details**

This plots a true histogram, a density estimate of total area 1. If `breaks` is specified, those break-points are used. Otherwise if `h` is specified, a regular grid of bins is used with width `h`. If neither `breaks` nor `h` is specified, `nbins` is used to select a suitable `h`.

**Side Effects**

A histogram is plotted on the current device.

 ucv

*Unbiased Cross-Validation for Bandwidth Selection*

---

**Description**

Uses unbiased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
ucv(x, nb = 1000, lower, upper)
```

**Arguments**

|                           |                                                                          |
|---------------------------|--------------------------------------------------------------------------|
| <code>x</code>            | a numeric vector                                                         |
| <code>nb</code>           | number of bins to use.                                                   |
| <code>lower, upper</code> | Range over which to minimize. The default is almost always satisfactory. |

**Value**

a bandwidth.

UScereal

*Nutritional and Marketing Information on US Cereals***Description**

The UScereal data frame has 65 rows and 11 columns. The data come from the 1993 ASA Statistical Graphics Exposition, and are taken from the mandatory F&DA food label. The data have been normalized here to a portion of one American cup.

**Usage**

UScereal

**Format**

This data frame contains the following columns:

mfr Manufacturer, represented by its first initial: G=General Mills, K=Kelloggs, N=Nabisco, P=Post, Q=Quaker Oats, R=Ralston Purina.

calories number of calories in one portion.

protein grams of protein in one portion.

fat grams of fat in one portion.

sodium milligrams of sodium in one portion.

fibre grams of dietary fibre in one portion.

carbo grams of complex carbohydrates in one portion.

sugars grams of sugars in one portion.

shelf display shelf (1, 2, or 3, counting from the floor).

potassium grams of potassium.

vitamins vitamins and minerals (none, enriched, or 100%).

**Source**

The original data are available at <https://lib.stat.cmu.edu/datasets/1993.expo/>.

**References**

UScrime

*The Effect of Punishment Regimes on Crime Rates***Description**

Criminologists are interested in the effect of punishment regimes on crime rates. This has been studied using aggregate data on 47 states of the USA for 1960 given in this data frame. The variables seem to have been re-scaled to convenient numbers.

**Usage**

```
UScrime
```

**Format**

This data frame contains the following columns:

M percentage of males aged 14–24.

So indicator variable for a Southern state.

Ed mean years of schooling.

Po1 police expenditure in 1960.

Po2 police expenditure in 1959.

LF labour force participation rate.

M.F number of males per 1000 females.

Pop state population.

NW number of non-whites per 1000 people.

U1 unemployment rate of urban males 14–24.

U2 unemployment rate of urban males 35–39.

GDP gross domestic product per head.

Ineq income inequality.

Prob probability of imprisonment.

Time average time served in state prisons.

y rate of crimes in a particular category per head of population.

 waders

*Counts of Waders at 15 Sites in South Africa*

---

**Description**

The waders data frame has 15 rows and 19 columns. The entries are counts of waders in summer.

**Usage**

waders

**Format**

This data frame contains the following columns (species)

S1 Oystercatcher  
 S2 White-fronted Plover  
 S3 Kitt Lutz's Plover  
 S4 Three-banded Plover  
 S5 Grey Plover  
 S6 Ringed Plover  
 S7 Bar-tailed Godwit  
 S8 Whimbrel  
 S9 Marsh Sandpiper  
 S10 Greenshank  
 S11 Common Sandpiper  
 S12 Turnstone  
 S13 Knot  
 S14 Sanderling  
 S15 Little Stint  
 S16 Curlew Sandpiper  
 S17 Ruff  
 S18 Avocet  
 S19 Black-winged Stilt

The rows are the sites:

A = Namibia North coast  
 B = Namibia North wetland  
 C = Namibia South coast  
 D = Namibia South wetland  
 E = Cape North coast  
 F = Cape North wetland  
 G = Cape West coast  
 H = Cape West wetland  
 I = Cape South coast  
 J = Cape South wetland  
 K = Cape East coast  
 L = Cape East wetland  
 M = Transkei coast  
 N = Natal coast  
 O = Natal wetland

**Examples**

```
plot(corresp(waders, nf=2))
```

whiteside

*House Insulation: Whiteside's Data***Description**

Mr Derek Whiteside of the UK Building Research Station recorded the weekly gas consumption and average external temperature at his own house in south-east England for two heating seasons, one of 26 weeks before, and one of 30 weeks after cavity-wall insulation was installed. The object of the exercise was to assess the effect of the insulation on gas consumption.

**Usage**

whiteside

**Format**

The whiteside data frame has 56 rows and 3 columns.:

Insul A factor, before or after insulation.

Temp Purportedly the average outside temperature in degrees Celsius. (These values is far too low for any 56-week period in the 1960s in South-East England. It might be the weekly average of daily minima.)

Gas The weekly gas consumption in 1000s of cubic feet.

**Source**

A data set collected in the 1960s by Mr Derek Whiteside of the UK Building Research Station. Reported by

Hand, D. J., Daly, F., McConway, K., Lunn, D. and Ostrowski, E. eds (1993) *A Handbook of Small Data Sets*. Chapman & Hall, p. 69.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Examples**

```
require(lattice)
xyplot(Gas ~ Temp | Insul, whiteside, panel =
 function(x, y, ...) {
 panel.xyplot(x, y, ...)
 panel.lmline(x, y, ...)
 }, xlab = "Average external temperature (deg. C)",
 ylab = "Gas consumption (1000 cubic feet)", aspect = "xy",
 strip = function(...) strip.default(..., style = 1))

gasB <- lm(Gas ~ Temp, whiteside, subset = Insul=="Before")
gasA <- update(gasB, subset = Insul=="After")
summary(gasB)
summary(gasA)
gasBA <- lm(Gas ~ Insul/Temp - 1, whiteside)
summary(gasBA)
```

```
gasQ <- lm(Gas ~ Insul/(Temp + I(Temp^2)) - 1, whiteside)
coef(summary(gasQ))

gasPR <- lm(Gas ~ Insul + Temp, whiteside)
anova(gasPR, gasBA)
options(contrasts = c("contr.treatment", "contr.poly"))
gasBA1 <- lm(Gas ~ Insul*Temp, whiteside)
coef(summary(gasBA1))
```

width.SJ

*Bandwidth Selection by Pilot Estimation of Derivatives***Description**

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))
```

**Arguments**

|              |                                                                  |
|--------------|------------------------------------------------------------------|
| x            | a numeric vector                                                 |
| nb           | number of bins to use.                                           |
| upper, lower | range over which to search for solution if method = "ste".       |
| method       | Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in"). |

**Value**

a bandwidth.

**Note**

A faster version for large n (thousands) is available in  $R \geq 3.4.0$  as part of [bw.SJ](#): quadruple its value for comparability with this version.

```

---

write.matrix

---

Write a Matrix or Data Frame

---

**Description**

Writes a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

**Usage**

```
write.matrix(x, file = "", sep = " ", blocksize)
```

**Arguments**

|           |                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | matrix or data frame.                                                                                                                                    |
| file      | name of output file. The default ("") is the console.                                                                                                    |
| sep       | The separator between columns.                                                                                                                           |
| blocksize | If supplied and positive, the output is written in blocks of blocksize rows. Choose as large as possible consistent with the amount of memory available. |

**Details**

If x is a matrix, supplying blocksize is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.

If x is a data frame, the conversion to a matrix may negate the memory saving.

**Side Effects**

A formatted file is produced, with column headings (if x has them) and columns of data.

wtloss*Weight Loss Data from an Obese Patient*

---

**Description**

The data frame gives the weight, in kilograms, of an obese patient at 52 time points over an 8 month period of a weight rehabilitation programme.

**Usage**

```
wtloss
```

**Format**

This data frame contains the following columns:

Days time in days since the start of the programme.

Weight weight in kilograms of the patient.

**Source**

Dr T. Davies, Adelaide.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Examples**

```
IGNORE_RDIFF_BEGIN
wtloss.fm <- nls(Weight ~ b0 + b1*2^(-Days/th),
 data = wtloss, start = list(b0=90, b1=95, th=120))
wtloss.fm
IGNORE_RDIFF_END
plot(wtloss)
with(wtloss, lines(Days, fitted(wtloss.fm)))
```

## Chapter 17

# The Matrix package

---

abIndex-class

*Class "abIndex" of Abstract Index Vectors*

---

### Description

The "abIndex" [class](#), short for "Abstract Index Vector", is used for dealing with large index vectors more efficiently, than using integer (or [numeric](#)) vectors of the kind `2:1000000` or `c(0:1e5, 1000:1e6)`.

Note that the current implementation details are subject to change, and if you consider working with these classes, please contact the package maintainers (`packageDescription("Matrix")$Maintainer`).

### Objects from the Class

Objects can be created by calls of the form `new("abIndex", ...)`, but more easily and typically either by `as(x, "abIndex")` where `x` is an integer (valued) vector, or directly by `abIseq()` and combination `c(...)` of such.

### Slots

**kind**: a [character](#) string, one of `("int32", "double", "rleDiff")`, denoting the internal structure of the abIndex object.

**x**: Object of class "numLike"; is used (i.e., not of length 0) only iff the object is *not* compressed, i.e., currently exactly when `kind != "rleDiff"`.

**rleD**: object of class "[rleDiff](#)", used for compression via [rle](#).

### Methods

**as.numeric, as.integer, as.vector** signature(`x = "abIndex"`): ...

[ signature(`x = "abIndex"`, `i = "index"`, `j = "ANY"`, `drop = "ANY"`): ...

**coerce** signature(`from = "numeric"`, `to = "abIndex"`): ...

**coerce** signature(`from = "abIndex"`, `to = "numeric"`): ...

**coerce** signature(`from = "abIndex"`, `to = "integer"`): ...

**length** signature(`x = "abIndex"`): ...

**Ops** signature(e1 = "numeric", e2 = "abIndex"): These and the following arithmetic and logic operations are **not yet implemented**; see [Ops](#) for a list of these (S4) group methods.

**Ops** signature(e1 = "abIndex", e2 = "abIndex"): ...

**Ops** signature(e1 = "abIndex", e2 = "numeric"): ...

**Summary** signature(x = "abIndex"): ...

**show** ("abIndex"): simple [show](#) method, building on show(<rleDiff>).

**is.na** ("abIndex"): works analogously to regular vectors.

**is.finite, is.infinite** ("abIndex"): ditto.

### Note

This is currently experimental and not yet used for our own code. Please contact us (packageDescription("Matrix")\$Maintainer), if you plan to make use of this class.

Partly builds on ideas and code from Jens Oehlschlaegel, as implemented (around 2008, in the GPL'ed part of) package **ff**.

### See Also

[rle](#) ([base](#)) which is used here; [numeric](#)

### Examples

```
showClass("abIndex")
ii <- c(-3:40, 20:70)
str(ai <- as(ii, "abIndex"))# note
ai # -> show() method

stopifnot(identical(-3:20,
 as(abIseq1(-3,20), "vector")))
```

---

abIseq

*Sequence Generation of "abIndex", Abstract Index Vectors*

---

### Description

Generation of abstract index vectors, i.e., objects of class "[abIndex](#)".

[abIseq\(\)](#) is designed to work entirely like [seq](#), but producing "abIndex" vectors.

[abIseq1\(\)](#) is its basic building block, where [abIseq1](#)(n,m) corresponds to n:m.

[c](#)(x, ...) will return an "abIndex" vector, when x is one.

### Usage

```
abIseq1(from = 1, to = 1)
abIseq (from = 1, to = 1, by = ((to - from)/(length.out - 1)),
 length.out = NULL, along.with = NULL)

S3 method for class 'abIndex'
c(...)
```

**Arguments**

|            |                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| from, to   | the starting and (maximal) end value of the sequence.                                                                                                     |
| by         | number: increment of the sequence.                                                                                                                        |
| length.out | desired length of the sequence. A non-negative number, which for seq and seq.int will be rounded up if fractional.                                        |
| along.with | take the length from the length of this argument.                                                                                                         |
| ...        | in general an arbitrary number of R objects; here, when the first is an "abIndex" vector, these arguments will be concatenated to a new "abIndex" object. |

**Value**

An abstract index vector, i.e., object of class "abIndex".

**See Also**

the class [abIndex](#) documentation; [rep2abI\(\)](#) for another constructor; [rle](#) (**base**).

**Examples**

```
stopifnot(identical(-3:20,
 as(abIseq1(-3,20), "vector")))

try(## (arithmetic) not yet implemented
abIseq(1, 50, by = 3)
)
```

---

all.equal-methods

---

*Matrix Package Methods for Function all.equal()*

---

**Description**

Methods for function [all.equal\(\)](#) (from R package **base**) are defined for all [Matrix](#) classes.

**Methods**

**target = "Matrix", current = "Matrix" \**

**target = "ANY", current = "Matrix" \**

**target = "Matrix", current = "ANY"** these three methods are simply using [all.equal.numeric](#) directly and work via [as.vector\(\)](#).

There are more methods, notably also for "[sparseVector](#)"s, see `showMethods("all.equal")`.

Examples

```
showMethods("all.equal")

(A <- spMatrix(3,3, i= c(1:3,2:1), j=c(3:1,1:2), x = 1:5))
ex <- expand(lu. <- lu(A))
stopifnot(all.equal(as(A[lu.@p + 1L, lu.@q + 1L], "CsparseMatrix"),
 lu.@L %%% lu.@U),
 with(ex, all.equal(as(P %%% A %%% t(Q), "CsparseMatrix"),
 L %%% U)),
 with(ex, all.equal(as(A, "CsparseMatrix"),
 t(P) %%% L %%% U %%% Q)))
```

---

|           |                                                      |
|-----------|------------------------------------------------------|
| asUniqueT | <i>Standardize a Sparse Matrix in Triplet Format</i> |
|-----------|------------------------------------------------------|

---

Description

Detect or standardize a [TsparseMatrix](#) with unsorted or duplicated  $(i, j)$  pairs.

Usage

```
anyDuplicatedT(x, ...)
isUniqueT(x, byrow = FALSE, isT = is(x, "TsparseMatrix"))
asUniqueT(x, byrow = FALSE, isT = is(x, "TsparseMatrix"))
aggregateT(x)
```

Arguments

- x an R object. `anyDuplicatedT` and `aggregateT` require x inheriting from [TsparseMatrix](#). `asUniqueT` requires x inheriting from [Matrix](#) and coerces x to [TsparseMatrix](#) if necessary.
- ... optional arguments passed to the default method for generic function [anyDuplicated](#).
- byrow a logical indicating if x should be sorted by row then by column.
- isT a logical indicating if x inherits from virtual class [TsparseMatrix](#).

Value

`anyDuplicatedT(x)` returns the index of the first duplicated  $(i, j)$  pair in x (0 if there are no duplicated pairs).

`isUniqueT(x)` returns TRUE if x is a [TsparseMatrix](#) with sorted, nonduplicated  $(i, j)$  pairs and FALSE otherwise.

`asUniqueT(x)` returns the unique [TsparseMatrix](#) representation of x with sorted, nonduplicated  $(i, j)$  pairs. Values corresponding to identical  $(i, j)$  pairs are aggregated by addition, where in the logical case “addition” refers to logical OR.

`aggregateT(x)` aggregates without sorting.

See Also

Virtual class [TsparseMatrix](#).

**Examples**

```

example("dgTMatrix-class", echo=FALSE)
-> 'T2' with (i,j,x) slots of length 5 each
T2u <- asUniqueT(T2)
stopifnot(## They "are" the same (and print the same):
 all.equal(T2, T2u, tol=0),
 ## but not internally:
 anyDuplicatedT(T2) == 2,
 anyDuplicatedT(T2u) == 0,
 length(T2 @x) == 5,
 length(T2u@x) == 3)

isUniqueT(T2) # FALSE
isUniqueT(T2u) # TRUE

T3 <- T2u
T3[1, c(1,3)] <- 10; T3[2, c(1,5)] <- 20
T3u <- asUniqueT(T3)
str(T3u) # sorted in 'j', and within j, sorted in i
stopifnot(isUniqueT(T3u))

Logical l.TMatrix and n.TMatrix :
(L2 <- T2 > 0)
validObject(L2u <- asUniqueT(L2))
(N2 <- as(L2, "nMatrix"))
validObject(N2u <- asUniqueT(N2))
stopifnot(N2u@i == L2u@i, L2u@i == T2u@i, N2@i == L2@i, L2@i == T2@i,
 N2u@j == L2u@j, L2u@j == T2u@j, N2@j == L2@j, L2@j == T2@j)
now with a nasty NA [partly failed in Matrix 1.1-5]:
L.0N <- L.1N <- L2
L.0N@x[1:2] <- c(FALSE, NA)
L.1N@x[1:2] <- c(TRUE, NA)
validObject(L.0N)
validObject(L.1N)
(m.0N <- as.matrix(L.0N))
(m.1N <- as.matrix(L.1N))
stopifnot(identical(10L, which(is.na(m.0N))), !anyNA(m.1N))
symnum(m.0N)
symnum(m.1N)

```

**Description**

Return the matrix obtained by setting to zero elements below a diagonal (`triu`), above a diagonal (`tril`), or outside of a general band (`band`).

**Usage**

```

band(x, k1, k2, ...)
triu(x, k = 0L, ...)
tril(x, k = 0L, ...)

```

**Arguments**

|                        |                                                                                                                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a matrix-like object                                                                                                                                                                                                                                       |
| <code>k, k1, k2</code> | integers specifying the diagonals that are not set to zero, $k1 \leq k2$ . These are interpreted relative to the main diagonal, which is $k = 0$ . Positive and negative values of $k$ indicate diagonals above and below the main diagonal, respectively. |
| <code>...</code>       | optional arguments passed to methods, currently unused by package <b>Matrix</b> .                                                                                                                                                                          |

**Details**

`triu(x, k)` is equivalent to `band(x, k, dim(x)[2])`. Similarly, `tril(x, k)` is equivalent to `band(x, -dim(x)[1], k)`.

**Value**

An object of a suitable matrix class, inheriting from `triangularMatrix` where appropriate. It inherits from `sparseMatrix` if and only if `x` does.

**Methods**

`x = "CsparseMatrix"` method for compressed, sparse, column-oriented matrices.

`x = "RsparseMatrix"` method for compressed, sparse, row-oriented matrices.

`x = "TsparseMatrix"` method for sparse matrices in triplet format.

`x = "diagonalMatrix"` method for diagonal matrices.

`x = "denseMatrix"` method for dense matrices in packed or unpacked format.

`x = "matrix"` method for traditional matrices of implicit class `matrix`.

**See Also**

`bandSparse` for the *construction* of a banded sparse matrix directly from its non-zero diagonals.

**Examples**

```
A random sparse matrix :
set.seed(7)
m <- matrix(0, 5, 5)
m[sample(length(m), size = 14)] <- rep(1:9, length=14)
(mm <- as(m, "CsparseMatrix"))

tril(mm) # lower triangle
tril(mm, -1) # strict lower triangle
triu(mm, 1) # strict upper triangle
band(mm, -1, 2) # general band
(m5 <- Matrix(rnorm(25), ncol = 5))
tril(m5) # lower triangle
tril(m5, -1) # strict lower triangle
triu(m5, 1) # strict upper triangle
band(m5, -1, 2) # general band
(m65 <- Matrix(rnorm(30), ncol = 5)) # not square
triu(m65) # result not "dtrMatrix" unless square
(sm5 <- crossprod(m65)) # symmetric
 band(sm5, -1, 1) # "dsyMatrix": symmetric band preserves symmetry property
as(band(sm5, -1, 1), "sparseMatrix") # often preferable
(sm <- round(crossprod(triu(mm/2)))) # sparse symmetric ("dsC*")
```

```
band(sm, -1,1) # remains "dsC", *however*
band(sm, -2,1) # -> "dgC"
```

bandSparse

*Construct Sparse Banded Matrix from (Sup-/Super-) Diagonals***Description**

Construct a sparse banded matrix by specifying its non-zero sup- and super-diagonals.

**Usage**

```
bandSparse(n, m = n, k, diagonals, symmetric = FALSE,
 repr = "C", giveCsparse = (repr == "C"))
```

**Arguments**

- |             |                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| n, m        | the matrix dimension $(n, m) = (nrow, ncol)$ .                                                                                                                                                                                                                                                                                                                                                                             |
| k           | integer vector of “diagonal numbers”, with identical meaning as in <code>band(*, k)</code> , i.e., relative to the main diagonal, which is $k=0$ .                                                                                                                                                                                                                                                                         |
| diagonals   | optional list of sub-/super- diagonals; if missing, the result will be a pattern matrix, i.e., inheriting from class <code>nMatrix</code> .<br>diagonals can also be $n' \times d$ matrix, where $d \leftarrow \text{length}(k)$ and $n' \geq \min(n, m)$ . In that case, the sub-/super- diagonals are taken from the columns of diagonals, where only the first several rows will be used (typically) for off-diagonals. |
| symmetric   | logical; if true the result will be symmetric (inheriting from class <code>symmetricMatrix</code> ) and only the upper or lower triangle must be specified (via $k$ and diagonals).                                                                                                                                                                                                                                        |
| repr        | <b>character</b> string, one of "C", "T", or "R", specifying the sparse <i>representation</i> to be used for the result, i.e., one from the super classes <code>CsparseMatrix</code> , <code>TsparseMatrix</code> , or <code>RsparseMatrix</code> .                                                                                                                                                                        |
| giveCsparse | <b>(deprecated, replaced with repr):</b> logical indicating if the result should be a <code>CsparseMatrix</code> or a <code>TsparseMatrix</code> , where the default was TRUE, and now is determined from repr; very often Csparse matrices are more efficient subsequently, but not always.                                                                                                                               |

**Value**

a sparse matrix (of `class CsparseMatrix`) of dimension  $n \times m$  with diagonal “bands” as specified.

**See Also**

`band`, for *extraction* of matrix bands; `bdiag`, `diag`, `sparseMatrix`, `Matrix`.

**Examples**

```

diags <- list(1:30, 10*(1:20), 100*(1:20))
s1 <- bandSparse(13, k = -c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
s1
s2 <- bandSparse(13, k = c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
stopifnot(identical(s1, t(s2)), is(s1,"dsCMatrix"))

a pattern Matrix of *full* (sub-)diagonals:
bk <- c(0:4, 7,9)
(s3 <- bandSparse(30, k = bk, symm = TRUE))

If you want a pattern matrix, but with "sparse"-diagonals,
you currently need to go via logical sparse:
llis <- lapply(list(rpois(20, 2), rpois(20, 1), rpois(20, 3))[c(1:3, 2:3, 3:2)],
 as.logical)
(s4 <- bandSparse(20, k = bk, symm = TRUE, diag = llis))
(s4. <- as(drop0(s4), "nsparseMatrix"))

n <- 1e4
bk <- c(0:5, 7,11)
bMat <- matrix(1:8, n, 8, byrow=TRUE)
bLis <- as.data.frame(bMat)
B <- bandSparse(n, k = bk, diag = bLis)
Bs <- bandSparse(n, k = bk, diag = bLis, symmetric=TRUE)
B [1:15, 1:30]
Bs[1:15, 1:30]
can use a list *or* a matrix for specifying the diagonals:
stopifnot(identical(B, bandSparse(n, k = bk, diag = bMat)),
 identical(Bs, bandSparse(n, k = bk, diag = bMat, symmetric=TRUE))
 , inherits(B, "dtCMatrix") # triangular!
)

```

bdiag

*Construct a Block Diagonal Matrix***Description**

Build a block diagonal matrix given several building block matrices.

**Usage**

```

bdiag(...)
.bdiag(lst)

```

**Arguments**

... individual matrices or a [list](#) of matrices.  
 lst non-empty [list](#) of matrices.

**Details**

For non-trivial argument list, `bdiag()` calls `.bdiag()`. The latter may be useful to programmers.

**Value**

A *sparse* matrix obtained by combining the arguments into a block diagonal matrix.

The value of `bdiag()` inherits from class `CsparseMatrix`, whereas `.bdiag()` returns a `TsparseMatrix`.

**Note**

This function has been written and is efficient for the case of relatively few block matrices which are typically sparse themselves.

It is currently *inefficient* for the case of many small dense block matrices. For the case of *many* dense  $k \times k$  matrices, the `bdiag_m()` function in the ‘Examples’ is an order of magnitude faster.

**Author(s)**

Martin Maechler, built on a version posted by Berton Gunter to R-help; earlier versions have been posted by other authors, notably Scott Chasalow to S-news. Doug Bates’s faster implementation builds on `TsparseMatrix` objects.

**See Also**

`Diagonal` for constructing matrices of class `diagonalMatrix`, or `kronecker` which also works for “Matrix” inheriting matrices.

`bandSparse` constructs a *banded* sparse matrix from its non-zero sub-/super - diagonals.

Note that other CRAN R packages have own versions of `bdiag()` which return traditional matrices.

**Examples**

```
bdiag(matrix(1:4, 2), diag(3))
combine "Matrix" class and traditional matrices:
bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))

mlist <- list(1, 2:3, diag(x=5:3), 27, cbind(1,3:6), 100:101)
bdiag(mlist)
stopifnot(identical(bdiag(mlist),
 bdiag(lapply(mlist, as.matrix))))

ml <- c(as(matrix((1:24)%% 11 == 0, 6,4), "nMatrix"),
 rep(list(Diagonal(2, x=TRUE)), 3))
mln <- c(ml, Diagonal(x = 1:3))
stopifnot(is(bdiag(ml), "lsparseMatrix"),
 is(bdiag(mln), "dsparseMatrix"))

random (diagonal-)block-triangular matrices:
rblockTri <- function(nb, max.ni, lambda = 3) {
 .bdiag(replicate(nb, {
 n <- sample.int(max.ni, 1)
 tril(Matrix(rpois(n * n, lambda = lambda), n, n)) }))
}

(T4 <- rblockTri(4, 10, lambda = 1))
image(T1 <- rblockTri(12, 20))

##' Fast version of Matrix :: .bdiag() -- for the case of *many* (k x k) matrices:
```

```
##' @param lmat list(<mat1>, <mat2>,, <mat_N>) where each mat_j is a k x k 'matrix'
##' @return a sparse (N*k x N*k) matrix of class \code{"\linkS4class{dgCMatrix}"}.
bdiag_m <- function(lmat) {
 ## Copyright (C) 2016 Martin Maechler, ETH Zurich
 if(!length(lmat)) return(new("dgCMatrix"))
 stopifnot(is.list(lmat), is.matrix(lmat[[1]]),
 (k <- (d <- dim(lmat[[1]]))[1]) == d[2], # k x k
 all(vapply(lmat, dim, integer(2)) == k)) # all of them
 N <- length(lmat)
 if(N * k > .Machine$integer.max)
 stop("resulting matrix too large; would be M x M, with M=", N*k)
 M <- as.integer(N * k)
 ## result: an M x M matrix
 new("dgCMatrix", Dim = c(M,M),
 ## 'i :' maybe there's a faster way (w/o matrix indexing), but elegant?
 i = as.vector(matrix(0L:(M-1L), nrow=k)[, rep(seq_len(N), each=k)]),
 p = k * 0L:M,
 x = as.double(unlist(lmat, recursive=FALSE, use.names=FALSE)))
}

l12 <- replicate(12, matrix(rpois(16, lambda = 6.4), 4, 4),
 simplify=FALSE)
dim(T12 <- bdiag_m(l12))# 48 x 48
T12[1:20, 1:20]
```

---

boolmatmult-methods      *Boolean Arithmetic Matrix Products: %%% and Methods*

---

## Description

For boolean or “pattern” matrices, i.e., R objects of class `nMatrix`, it is natural to allow matrix products using boolean instead of numerical arithmetic.

In package **Matrix**, we use the binary operator `%%` (aka “infix”) function) for this and provide methods for all our matrices and the traditional R matrices (see `matrix`).

## Value

a pattern matrix, i.e., inheriting from “`nMatrix`”, or an “`ldiMatrix`” in case of a diagonal matrix.

## Methods

We provide methods for both the “traditional” (R base) matrices and numeric vectors and conceptually all matrices and `sparseVectors` in package **Matrix**.

```
signature(x = "ANY", y = "ANY")
signature(x = "ANY", y = "Matrix")
signature(x = "Matrix", y = "ANY")
signature(x = "nMatrix", y = "nMatrix")
signature(x = "nMatrix", y = "nsparseMatrix")
signature(x = "nsparseMatrix", y = "nMatrix")
signature(x = "nsparseMatrix", y = "nsparseMatrix")
signature(x = "sparseVector", y = "sparseVector")
```

**Note**

These boolean arithmetic matrix products had been newly introduced for **Matrix** 1.2.0 (March 2015). Its implementation has still not been tested extensively.

Originally, it was left unspecified how non-structural zeros, i.e., 0's as part of the M@x slot should be treated for numeric ("**dMatrix**") and logical ("**lMatrix**") sparse matrices. We now specify that boolean matrix products should behave as if applied to `drop0(M)`, i.e., as if dropping such zeros from the matrix before using it.

Equivalently, for all matrices M, boolean arithmetic should work as if applied to  $M \neq 0$  (or  $M \neq \text{FALSE}$ ).

The current implementation ends up coercing both x and y to (virtual) class `nsparseMatrix` which may be quite inefficient for dense matrices. A future implementation may well return a matrix with **different** class, but the "same" content, i.e., the same matrix entries  $m_{ij}$ .

**See Also**

`%*%`, `crossprod()`, or `tcrossprod()`, for (regular) matrix product methods.

**Examples**

```
set.seed(7)
L <- Matrix(rnorm(20) > 1, 4, 5)
(N <- as(L, "nMatrix"))
L. <- L; L.[1:2,1] <- TRUE; L.@x[1:2] <- FALSE; L. # has "zeros" to drop0()
D <- Matrix(round(rnorm(30)), 5, 6) # -> values in -1:1 (for this seed)
L %%% D
stopifnot(identical(L %%% D, N %%% D),
 all(L %%% D == as((L %*% abs(D)) > 0, "sparseMatrix"))))

cross products , possibly with boolArith = TRUE :
crossprod(N) # -> sparse patter'n' (TRUE/FALSE : boolean arithmetic)
crossprod(N + 0) # -> numeric Matrix (with same "pattern")
stopifnot(all(crossprod(N) == t(N) %%% N),
 identical(crossprod(N), crossprod(N + 0, boolArith=TRUE)),
 identical(crossprod(L), crossprod(N, boolArith=FALSE)))
crossprod(D, boolArith = TRUE) # pattern: "nsCMatrix"
crossprod(L, boolArith = TRUE) # ditto
crossprod(L, boolArith = FALSE) # numeric: "dsCMatrix"
```

---

BunchKaufman-class      *Dense Bunch-Kaufman Factorizations*

---

**Description**

Classes BunchKaufman and pBunchKaufman represent Bunch-Kaufman factorizations of  $n \times n$  real, symmetric matrices  $A$ , having the general form

$$A = UD_UU' = LD_LL'$$

where  $D_U$  and  $D_L$  are symmetric, block diagonal matrices composed of  $b_U$  and  $b_L$   $1 \times 1$  or  $2 \times 2$  diagonal blocks;  $U = \prod_{k=1}^{b_U} P_k U_k$  is the product of  $b_U$  row-permuted unit upper triangular matrices, each having nonzero entries above the diagonal in 1 or 2 columns; and  $L = \prod_{k=1}^{b_L} P_k L_k$

is the product of  $b_L$  row-permuted unit lower triangular matrices, each having nonzero entries below the diagonal in 1 or 2 columns.

These classes store the nonzero entries of the  $2b_U + 1$  or  $2b_L + 1$  factors, which are individually sparse, in a dense format as a vector of length  $nn$  (BunchKaufman) or  $n(n+1)/2$  (pBunchKaufman), the latter giving the “packed” representation.

### Slots

`Dim`, `Dimnames` inherited from virtual class [MatrixFactorization](#).

`uplo` a string, either “U” or “L”, indicating which triangle (upper or lower) of the factorized symmetric matrix was used to compute the factorization and in turn how the `x` slot is partitioned.

`x` a numeric vector of length  $n*n$  (BunchKaufman) or  $n*(n+1)/2$  (pBunchKaufman), where  $n=Dim[1]$ . The details of the representation are specified by the manual for LAPACK routines `dsytrf` and `dsptrf`.

`perm` an integer vector of length  $n=Dim[1]$  specifying row and column interchanges as described in the manual for LAPACK routines `dsytrf` and `dsptrf`.

### Extends

Class [BunchKaufmanFactorization](#), directly. Class [MatrixFactorization](#), by class [BunchKaufmanFactorization](#), distance 2.

### Instantiation

Objects can be generated directly by calls of the form `new("BunchKaufman", ...)` or `new("pBunchKaufman", ...)`, but they are more typically obtained as the value of [BunchKaufman\(x\)](#) for `x` inheriting from [dsyMatrix](#) or [dspMatrix](#).

### Methods

`coerce signature(from = "BunchKaufman", to = "dtrMatrix")`: returns a [dtrMatrix](#), useful for inspecting the internal representation of the factorization; see ‘Note’.

`coerce signature(from = "pBunchKaufman", to = "dtpMatrix")`: returns a [dtpMatrix](#), useful for inspecting the internal representation of the factorization; see ‘Note’.

`determinant signature(from = "p?BunchKaufman", logarithm = "logical")`: computes the determinant of the factorized matrix  $A$  or its logarithm.

`expand1 signature(x = "p?BunchKaufman")`: see [expand1-methods](#).

`expand2 signature(x = "p?BunchKaufman")`: see [expand2-methods](#).

`solve signature(a = "p?BunchKaufman", b = .)`: see [solve-methods](#).

### Note

In **Matrix** < 1.6-0, class [BunchKaufman](#) extended [dtrMatrix](#) and class [pBunchKaufman](#) extended [dtpMatrix](#), reflecting the fact that the internal representation of the factorization is fundamentally triangular: there are  $n(n+1)/2$  “parameters”, and these can be arranged systematically to form an  $n \times n$  triangular matrix. **Matrix** 1.6-0 removed these extensions so that methods would no longer be inherited from [dtrMatrix](#) and [dtpMatrix](#). The availability of such methods gave the wrong impression that [BunchKaufman](#) and [pBunchKaufman](#) represent a (singular) matrix, when in fact they represent an ordered set of matrix factors.

The coercions `as(., "dtrMatrix")` and `as(., "dtpMatrix")` are provided for users who understand the caveats.

## Examples

```
showClass("BunchKaufman")
set.seed(1)

n <- 6L
(A <- forceSymmetric(Matrix(rnorm(n * n), n, n)))

With dimnames, to see that they are propagated :
dimnames(A) <- rep.int(list(paste0("x", seq_len(n))), 2L)

(bk.A <- BunchKaufman(A))
str(e.bk.A <- expand2(bk.A, complete = FALSE), max.level = 2L)
str(E.bk.A <- expand2(bk.A, complete = TRUE), max.level = 2L)

Underlying LAPACK representation
(m.bk.A <- as(bk.A, "dtrMatrix"))
stopifnot(identical(as(m.bk.A, "matrix"), `dim<-`(bk.A@x, bk.A@Dim)))

Number of factors is 2*b+1, b <= n, which can be nontrivial ...
(b <- (length(E.bk.A) - 1L) %% 2L)

ae1 <- function(a, b, ...) all.equal(as(a, "matrix"), as(b, "matrix"), ...)
ae2 <- function(a, b, ...) ae1(unname(a), unname(b), ...)

A ~ U DU U', U := prod(Pk Uk) in floating point
stopifnot(exprs = {
 identical(names(e.bk.A), c("U", "DU", "U."))
 identical(e.bk.A[["U"]], Reduce(`*`, E.bk.A[seq_len(b)]))
 identical(e.bk.A[["U."]], t(e.bk.A[["U"]]))
 ae1(A, with(e.bk.A, U %*% DU %*% U.))
})

Factorization handled as factorized matrix
b <- rnorm(n)
stopifnot(identical(det(A), det(bk.A)),
 identical(solve(A, b), solve(bk.A, b)))
```

## Description

Computes the Bunch-Kaufman factorization of an  $n \times n$  real, symmetric matrix  $A$ , which has the general form

$$A = UD_UU' = LD_LL'$$

where  $D_U$  and  $D_L$  are symmetric, block diagonal matrices composed of  $b_U$  and  $b_L$   $1 \times 1$  or  $2 \times 2$  diagonal blocks;  $U = \prod_{k=1}^{b_U} P_k U_k$  is the product of  $b_U$  row-permuted unit upper triangular matrices, each having nonzero entries above the diagonal in 1 or 2 columns; and  $L = \prod_{k=1}^{b_L} P_k L_k$  is the product of  $b_L$  row-permuted unit lower triangular matrices, each having nonzero entries below the diagonal in 1 or 2 columns.

Methods are built on LAPACK routines dsytrf and dsptrf.

## Usage

```
BunchKaufman(x, ...)
S4 method for signature 'dsyMatrix'
BunchKaufman(x, warnSing = TRUE, ...)
S4 method for signature 'dspMatrix'
BunchKaufman(x, warnSing = TRUE, ...)
S4 method for signature 'matrix'
BunchKaufman(x, uplo = "U", ...)
```

## Arguments

|                       |                                                                                                                                                                                                           |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | a <a href="#">finite</a> symmetric matrix or <a href="#">Matrix</a> to be factorized. If <code>x</code> is square but not symmetric, then it will be <i>treated</i> as symmetric; see <code>uplo</code> . |
| <code>warnSing</code> | a logical indicating if a <a href="#">warning</a> should be signaled for singular <code>x</code> .                                                                                                        |
| <code>uplo</code>     | a string, either "U" or "L", indicating which triangle of <code>x</code> should be used to compute the factorization.                                                                                     |
| <code>...</code>      | further arguments passed to or from methods.                                                                                                                                                              |

## Value

An object representing the factorization, inheriting from virtual class [BunchKaufmanFactorization](#). The specific class is [BunchKaufman](#) unless `x` inherits from virtual class [packedMatrix](#), in which case it is [pBunchKaufman](#).

Generic functions [expand1](#) and [expand2](#), for constructing matrix factors from the result.

Generic functions [Cholesky](#), [Schur](#), [lu](#), and [qr](#), for computing other factorizations.

## Examples

```
showMethods("BunchKaufman", inherited = FALSE)
set.seed(0)

data(CAex, package = "Matrix")
class(CAex) # dgCMatix
isSymmetric(CAex) # symmetric, but not formally

A <- as(CAex, "symmetricMatrix")
class(A) # dsCMatix

Have methods for denseMatrix (unpacked and packed),
but not yet sparseMatrix ...
Not run:
(bk.A <- BunchKaufman(A))

End(Not run)
(bk.A <- BunchKaufman(as(A, "unpackedMatrix"))))

A ~ U DU U' in floating point
str(e.bk.A <- expand2(bk.A), max.level = 2L)
stopifnot(all.equal(as(A, "matrix"), as(Reduce(`*`, e.bk.A), "matrix")))
```

---

CAex

*Albers' example Matrix with "Difficult" Eigen Factorization*

---

## Description

An example of a sparse matrix for which `eigen()` seemed to be difficult, an unscaled version of this has been posted to the web, accompanying an E-mail to R-help (<https://stat.ethz.ch/mailman/listinfo/r-help>), by Casper J Albers, Open University, UK.

## Usage

```
data(CAex)
```

## Format

This is a  $72 \times 72$  symmetric matrix with 216 non-zero entries in five bands, stored as sparse matrix of class `dgCMatix`.

## Details

Historical note (2006-03-30): In earlier versions of R, `eigen(CAex)` fell into an infinite loop whereas `eigen(CAex, EISPACK=TRUE)` had been okay.

## Examples

```
data(CAex, package = "Matrix")
str(CAex) # of class "dgCMatix"

image(CAex)# -> it's a simple band matrix with 5 bands
and the eigen values are basically 1 (42 times) and 0 (30 x):
```

```

zapsmall(ev <- eigen(CAex, only.values=TRUE)$values)
i.e., the matrix is symmetric, hence
sCA <- as(CAex, "symmetricMatrix")
and
stopifnot(class(sCA) == "dsCMatrix",
 as(sCA, "matrix") == as(CAex, "matrix"))

```

cbind2-methods

*'cbind()' and 'rbind()' recursively built on cbind2/rbind2*

## Description

The base functions `cbind` and `rbind` are defined for an arbitrary number of arguments and hence have the first formal argument `...`. Now, when S4 objects are found among the arguments, base `cbind()` and `rbind()` internally “dispatch” *recursively*, calling `cbind2` or `rbind2` respectively, where these have methods defined and so should dispatch appropriately.

`cbind2()` and `rbind2()` are from the **methods** package, i.e., standard R, and have been provided for binding together *two* matrices, where in **Matrix**, we have defined methods for these and the 'Matrix' matrices.

## Usage

```

cbind(..., deparse.level = 1)
rbind(..., deparse.level = 1)

S4 method for signature 'Matrix,Matrix'
cbind2(x, y, ...)
S4 method for signature 'Matrix,Matrix'
rbind2(x, y, ...)

```

## Arguments

|                            |                                                                                                                                                                                                               |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>           | for <code>[cr]bind</code> , vector- or matrix-like R objects to be bound together; for <code>[cr]bind2</code> , further arguments passed to or from methods; see <code>cbind</code> and <code>cbind2</code> . |
| <code>deparse.level</code> | integer controlling the construction of labels in the case of non-matrix-like arguments; see <code>cbind</code> .                                                                                             |
| <code>x, y</code>          | vector- or matrix-like R objects to be bound together.                                                                                                                                                        |

## Value

typically a ‘matrix-like’ object of a similar `class` as the first argument in `...`

Note that sometimes by default, the result is a `sparseMatrix` if one of the arguments is (even in the case where this is not efficient). In other cases, the result is chosen to be sparse when there are more zero entries than non-zero ones (as the default sparse in `Matrix()`).

## Author(s)

Martin Maechler

**Examples**

```
(a <- matrix(c(2:1,1:2), 2,2))

(M1 <- cbind(0, rbind(a, 7))) # a traditional matrix

D <- Diagonal(2)
(M2 <- cbind(4, a, D, -1, D, 0)) # a sparse Matrix

stopifnot(validObject(M2), inherits(M2, "sparseMatrix"),
 dim(M2) == c(2,9))
```

---

CHMfactor-class

*Sparse Cholesky Factorizations*

---

**Description**

CHMfactor is the virtual class of sparse Cholesky factorizations of  $n \times n$  real, symmetric matrices  $A$ , having the general form

$$P_1 A P_1' = L_1 D L_1' \stackrel{D_{jj} \geq 0}{=} L L'$$

or (equivalently)

$$A = P_1' L_1 D L_1' P_1 \stackrel{D_{jj} \geq 0}{=} P_1' L L' P_1$$

where  $P_1$  is a permutation matrix,  $L_1$  is a unit lower triangular matrix,  $D$  is a diagonal matrix, and  $L = L_1 \sqrt{D}$ . The second equalities hold only for positive semidefinite  $A$ , for which the diagonal entries of  $D$  are non-negative and  $\sqrt{D}$  is well-defined.

The implementation of class CHMfactor is based on CHOLMOD's C-level `cholmod_factor_struct`. Virtual subclasses CHMsimpl and CHMsuper separate the simplicial and supernodal variants. These have nonvirtual subclasses `[dn]CHMsimpl` and `[dn]CHMsuper`, where prefix 'd' and prefix 'n' are reserved for numeric and symbolic factorizations, respectively.

**Usage**

```
isLDL(x)
```

**Arguments**

**x** an object inheriting from virtual class CHMfactor, almost always the result of a call to generic function [Cholesky](#).

**Value**

`isLDL(x)` returns TRUE or FALSE: TRUE if  $x$  stores the lower triangular entries of  $L_1 - I + D$ , FALSE if  $x$  stores the lower triangular entries of  $L$ .

**Slots**

Of CHMfactor:

Dim, Dimnames inherited from virtual class [MatrixFactorization](#).

colcount an integer vector of length Dim[1] giving an *estimate* of the number of nonzero entries in each column of the lower triangular Cholesky factor. If symbolic analysis was performed prior to factorization, then the estimate is exact.

perm a 0-based integer vector of length Dim[1] specifying the permutation applied to the rows and columns of the factorized matrix. perm of length 0 is valid and equivalent to the identity permutation, implying no pivoting.

type an integer vector of length 6 specifying details of the factorization. The elements correspond to members ordering, is\_ll, is\_super, is\_monotonic, maxcsize, and maxesize of the original cholmod\_factor\_struct. Simplicial and supernodal factorizations are distinguished by is\_super. Simplicial factorizations do not use maxcsize or maxesize. Supernodal factorizations do not use is\_ll or is\_monotonic.

Of CHMsimpl (all unused by nCHMsimpl):

nz an integer vector of length Dim[1] giving the number of nonzero entries in each column of the lower triangular Cholesky factor. There is at least one nonzero entry in each column, because the diagonal elements of the factor are stored explicitly.

p an integer vector of length Dim[1]+1. Row indices of nonzero entries in column j of the lower triangular Cholesky factor are obtained as i[p[j]+seq\_len(nz[j]))+1.

i an integer vector of length greater than or equal to sum(nz) containing the row indices of nonzero entries in the lower triangular Cholesky factor. These are grouped by column and sorted within columns, but the columns themselves need not be ordered monotonically. Columns may be overallocated, i.e., the number of elements of i reserved for column j may exceed nz[j].

prv, nxt integer vectors of length Dim[1]+2 indicating the order in which the columns of the lower triangular Cholesky factor are stored in i and x. Starting from  $j \leftarrow \text{Dim}[1]+2$ , the recursion  $j \leftarrow \text{nxt}[j+1]+1$  traverses the columns in forward order and terminates when  $\text{nxt}[j+1] = -1$ . Starting from  $j \leftarrow \text{Dim}[1]+1$ , the recursion  $j \leftarrow \text{prv}[j+1]+1$  traverses the columns in backward order and terminates when  $\text{prv}[j+1] = -1$ .

Of dCHMsimpl:

x a numeric vector parallel to i containing the corresponding nonzero entries of the lower triangular Cholesky factor  $L$  or (if and only if type[2] is 0) of the lower triangular matrix  $L_1 - I + D$ .

Of CHMsuper:

super, pi, px integer vectors of length nsuper+1, where nsuper is the number of supernodes. super[j]+1 is the index of the leftmost column of supernode j. The row indices of supernode j are obtained as s[pi[j]+seq\_len(pi[j+1]-pi[j]))+1. The numeric entries of supernode j are obtained as x[px[j]+seq\_len(px[j+1]-px[j]))+1 (if slot x is available).

s an integer vector of length greater than or equal to Dim[1] containing the row indices of the supernodes. s may contain duplicates, but not within a supernode, where the row indices must be increasing.

Of dCHMsuper:

x a numeric vector of length less than or equal to prod(Dim) containing the numeric entries of the supernodes.

## Extends

Class [MatrixFactorization](#), directly.

## Instantiation

Objects can be generated directly by calls of the form `new("dCHMsimpl", ...)`, etc., but `dCHMsimpl` and `dCHMsuper` are more typically obtained as the value of `Cholesky(x, ...)` for `x` inheriting from [sparseMatrix](#) (often [dsCMatrix](#)).

There is currently no API outside of calls to `new` for generating `nCHMsimpl` and `nCHMsuper`. These classes are vestigial and may be formally deprecated in a future version of **Matrix**.

## Methods

`coerce` signature(`from` = "CHMsimpl", `to` = "dtCMatrix"): returns a [dtCMatrix](#) representing the lower triangular Cholesky factor  $L$  or the lower triangular matrix  $L_1 - I + D$ , the latter if and only if `from@type[2]` is 0.

`coerce` signature(`from` = "CHMsuper", `to` = "dgCMatrix"): returns a [dgCMatrix](#) representing the lower triangular Cholesky factor  $L$ . Note that, for supernodes spanning two or more columns, the supernodal algorithm by design stores non-structural zeros above the main diagonal, hence [dgCMatrix](#) is indeed more appropriate than [dtCMatrix](#) as a coercion target.

`determinant` signature(`from` = "CHMfactor", `logarithm` = "logical"): behaves according to an optional argument `sqrt`. If `sqrt` = FALSE, then this method computes the determinant of the factorized matrix  $A$  or its logarithm. If `sqrt` = TRUE, then this method computes the determinant of the factor  $L = L_1 \text{sqrt}(D)$  or its logarithm, giving NaN for the modulus when  $D$  has negative diagonal elements. For backwards compatibility, the default value of `sqrt` is TRUE, but that can be expected change in a future version of **Matrix**, hence defensive code will always set `sqrt` (to TRUE, if the code must remain backwards compatible with **Matrix** < 1.6-0). Calls to this method not setting `sqrt` may warn about the pending change. The warnings can be disabled with `options(Matrix.warnSqrtDefault = 0)`.

`diag` signature(`x` = "CHMfactor"): returns a numeric vector of length  $n$  containing the diagonal elements of  $D$ , which (if they are all non-negative) are the squared diagonal elements of  $L$ .

`expand` signature(`x` = "CHMfactor"): see [expand-methods](#).

`expand1` signature(`x` = "CHMsimpl"): see [expand1-methods](#).

`expand1` signature(`x` = "CHMsuper"): see [expand1-methods](#).

`expand2` signature(`x` = "CHMsimpl"): see [expand2-methods](#).

`expand2` signature(`x` = "CHMsuper"): see [expand2-methods](#).

`image` signature(`x` = "CHMfactor"): see [image-methods](#).

`nnzero` signature(`x` = "CHMfactor"): see [nnzero-methods](#).

`solve` signature(`a` = "CHMfactor", `b` = .): see [solve-methods](#).

`update` signature(`object` = "CHMfactor"): returns a copy of `object` with the same nonzero pattern but with numeric entries updated according to additional arguments `parent` and `mult`, where `parent` is (coercible to) a [dsCMatrix](#) or a [dgCMatrix](#) and `mult` is a numeric vector of positive length.

The numeric entries are updated with those of the Cholesky factor of  $F(\text{parent}) + \text{mult}[1] * I$ , i.e.,  $F(\text{parent})$  plus `mult[1]` times the identity matrix, where  $F$  = [identity](#) for symmetric `parent` and  $F$  = [tcrossprod](#) for other `parent`. The nonzero pattern of  $F(\text{parent})$  must match that of  $S$  if `object` = `Cholesky(S, ...)`.

`updown` signature(`update` = ., `C` = ., `object` = "CHMfactor"): see [updown-methods](#).

chol-methods

*Compute the Cholesky Factor of a Matrix*

## Description

Computes the upper triangular Cholesky factor of an  $n \times n$  real, symmetric, positive semidefinite matrix  $A$ , optionally after pivoting. That is the factor  $L'$  in

$$P_1 A P_1' = L L'$$

or (equivalently)

$$A = P_1' L L' P_1$$

where  $P_1$  is a permutation matrix.

Methods for [denseMatrix](#) are built on LAPACK routines `dpstrf`, `dpotrf`, and `dpptrf`. The latter two do not permute rows or columns, so that  $P_1$  is an identity matrix.

Methods for [sparseMatrix](#) are built on CHOLMOD routines `cholmod_analyze` and `cholmod_factorize_p`.

## Usage

```

chol(x, ...)
S4 method for signature 'dsyMatrix'
chol(x, pivot = FALSE, tol = -1, ...)
S4 method for signature 'dspMatrix'
chol(x, ...)
S4 method for signature 'dsCMatrix'
chol(x, pivot = FALSE, ...)
S4 method for signature 'ddiMatrix'
chol(x, ...)
S4 method for signature 'generalMatrix'
chol(x, uplo = "U", ...)
S4 method for signature 'triangularMatrix'
chol(x, uplo = "U", ...)

```

## Arguments

**x** a [finite](#), symmetric, positive semidefinite matrix or [Matrix](#) to be factorized. If  $x$  is square but not symmetric, then it will be *treated* as symmetric; see `uplo`. Methods for dense  $x$  require positive definiteness when `pivot = FALSE`. Methods for sparse (but not diagonal)  $x$  require positive definiteness unconditionally.

|                    |                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pivot</code> | a logical indicating if the rows and columns of $x$ should be pivoted. Methods for sparse $x$ employ the approximate minimum degree (AMD) algorithm in order to reduce fill-in, i.e., without regard for numerical stability.                                                           |
| <code>tol</code>   | a <a href="#">finite</a> numeric tolerance, used only if <code>pivot = TRUE</code> . The factorization algorithm stops if the pivot is less than or equal to <code>tol</code> . Negative <code>tol</code> is equivalent to <code>nrow(x) * .Machine\$double.eps * max(diag(x))</code> . |
| <code>uplo</code>  | a string, either "U" or "L", indicating which triangle of $x$ should be used to compute the factorization. The default is "U", even for lower triangular $x$ , to be consistent with <a href="#">chol</a> from <b>base</b> .                                                            |
| <code>...</code>   | further arguments passed to or from methods.                                                                                                                                                                                                                                            |

### Details

For  $x$  inheriting from [diagonalMatrix](#), the diagonal result is computed directly and without pivoting, i.e., bypassing CHOLMOD.

For all other  $x$ , `chol(x, pivot = value)` calls [Cholesky](#)( $x$ , `perm = value`, ...) under the hood. If you must know the permutation  $P_1$  in addition to the Cholesky factor  $L'$ , then call [Cholesky](#) directly, as the result of `chol(x, pivot = TRUE)` specifies  $L'$  but not  $P_1$ .

### Value

A matrix, [triangularMatrix](#), or [diagonalMatrix](#) representing the upper triangular Cholesky factor  $L'$ . The result is a traditional matrix if  $x$  is a traditional matrix, dense if  $x$  is dense, and sparse if  $x$  is sparse.

chol2inv-methods

*Inverse from Cholesky Factor*

## Description

Given *formally* upper and lower triangular matrices  $U$  and  $L$ , compute  $(U'U)^{-1}$  and  $(LL')^{-1}$ , respectively.

This function can be seen as way to compute the inverse of a symmetric positive definite matrix given its Cholesky factor. Equivalently, it can be seen as a way to compute  $(X'X)^{-1}$  given the  $R$  part of the QR factorization of  $X$ , if  $R$  is constrained to have positive diagonal entries.

## Usage

```

chol2inv(x, ...)
S4 method for signature 'dtrMatrix'
chol2inv(x, ...)
S4 method for signature 'dtCMatrix'
chol2inv(x, ...)
S4 method for signature 'generalMatrix'
chol2inv(x, uplo = "U", ...)

```

## Arguments

**x** a square matrix or [Matrix](#), typically the result of a call to [chol](#). If  $x$  is square but not (formally) triangular, then only the upper or lower triangle is considered, depending on optional argument `uplo` if  $x$  is a [Matrix](#).

`uplo` a string, either "U" or "L", indicating which triangle of `x` contains the Cholesky factor. The default is "U", to be consistent with `chol2inv` from **base**.

`...` further arguments passed to or from methods.

### Value

A matrix, `symmetricMatrix`, or `diagonalMatrix` representing the inverse of the positive definite matrix whose Cholesky factor is `x`. The result is a traditional matrix if `x` is a traditional matrix, dense if `x` is dense, and sparse if `x` is sparse.

### See Also

The default method from **base**, `chol2inv`, called for traditional matrices `x`.

Generic function `chol`, for computing the upper triangular Cholesky factor  $L'$  of a symmetric positive semidefinite matrix.

Generic function `solve`, for solving linear systems and (as a corollary) for computing inverses more generally.

### Examples

```
(A <- Matrix(cbind(c(1, 1, 1), c(1, 2, 4), c(1, 4, 16))))
(R <- chol(A))
(L <- t(R))
(R2i <- chol2inv(R))
(L2i <- chol2inv(R))
stopifnot(exprs = {
 all.equal(R2i, tcrossprod(solve(R)))
 all.equal(L2i, crossprod(solve(L)))
 all.equal(as(R2i %%% A, "matrix"), diag(3L)) # the identity
 all.equal(as(L2i %%% A, "matrix"), diag(3L)) # ditto
})
```

---

Cholesky-class

Dense Cholesky Factorizations

---

### Description

Classes `Cholesky` and `pCholesky` represent dense, pivoted Cholesky factorizations of  $n \times n$  real, symmetric, positive semidefinite matrices  $A$ , having the general form

$$P_1 A P_1' = L_1 D L_1' = L L'$$

or (equivalently)

$$A = P_1' L_1 D L_1' P_1 = P_1' L L' P_1$$

where  $P_1$  is a permutation matrix,  $L_1$  is a unit lower triangular matrix,  $D$  is a non-negative diagonal matrix, and  $L = L_1 \sqrt{D}$ .

These classes store the entries of the Cholesky factor  $L$  or its transpose  $L'$  in a dense format as a vector of length  $nn$  (`Cholesky`) or  $n(n+1)/2$  (`pCholesky`), the latter giving the “packed” representation.

## Slots

Dim, Dimnames inherited from virtual class [MatrixFactorization](#).

uplo a string, either "U" or "L", indicating which triangle (upper or lower) of the factorized symmetric matrix was used to compute the factorization and in turn whether x stores  $L'$  or  $L$ .

x a numeric vector of length  $n*n$  (Cholesky) or  $n*(n+1)/2$  (pCholesky), where  $n=Dim[1]$ , listing the entries of the Cholesky factor  $L$  or its transpose  $L'$  in column-major order.

perm a 1-based integer vector of length  $Dim[1]$  specifying the permutation applied to the rows and columns of the factorized matrix. perm of length 0 is valid and equivalent to the identity permutation, implying no pivoting.

## Extends

Class [CholeskyFactorization](#), directly. Class [MatrixFactorization](#), by class [CholeskyFactorization](#), distance 2.

## Instantiation

Objects can be generated directly by calls of the form `new("Cholesky", ...)` or `new("pCholesky", ...)`, but they are more typically obtained as the value of [Cholesky](#)(x) for x inheriting from [dsyMatrix](#) or [dspMatrix](#) (often the subclasses of those reserved for positive semidefinite matrices, namely [dpoMatrix](#) and [dppMatrix](#)).

## Methods

coerce signature(from = "Cholesky", to = "dtrMatrix"): returns a [dtrMatrix](#) representing the Cholesky factor  $L$  or its transpose  $L'$ ; see 'Note'.

coerce signature(from = "pCholesky", to = "dtpMatrix"): returns a [dtpMatrix](#) representing the Cholesky factor  $L$  or its transpose  $L'$ ; see 'Note'.

determinant signature(from = "p?Cholesky", logarithm = "logical"): computes the determinant of the factorized matrix  $A$  or its logarithm.

diag signature(x = "p?Cholesky"): returns a numeric vector of length  $n$  containing the diagonal elements of  $D$ , which are the squared diagonal elements of  $L$ .

expand1 signature(x = "p?Cholesky"): see [expand1-methods](#).

expand2 signature(x = "p?Cholesky"): see [expand2-methods](#).

solve signature(a = "p?Cholesky", b = .): see [solve-methods](#).

## Note

In **Matrix** <1.6-0, class Cholesky extended [dtrMatrix](#) and class pCholesky extended [dtpMatrix](#), reflecting the fact that the factor  $L$  is indeed a triangular matrix. **Matrix** 1.6-0 removed these extensions so that methods would no longer be inherited from [dtrMatrix](#) and [dtpMatrix](#). The availability of such methods gave the wrong impression that Cholesky and pCholesky represent a (singular) matrix, when in fact they represent an ordered set of matrix factors.

The coercions `as(., "dtrMatrix")` and `as(., "dtpMatrix")` are provided for users who understand the caveats.

Generic functions [Cholesky](#), [expand1](#) and [expand2](#).

## Examples

```
showClass("Cholesky")
set.seed(1)

m <- 30L
n <- 6L
(A <- crossprod(Matrix(rnorm(m * n), m, n)))

With dimnames, to see that they are propagated :
dimnames(A) <- dn <- rep.int(list(paste0("x", seq_len(n))), 2L)

(ch.A <- Cholesky(A)) # pivoted, by default
str(e.ch.A <- expand2(ch.A, LDL = TRUE), max.level = 2L)
str(E.ch.A <- expand2(ch.A, LDL = FALSE), max.level = 2L)

Underlying LAPACK representation
(m.ch.A <- as(ch.A, "dtrMatrix")) # which is L', not L, because
A@uplo == "U"
stopifnot(identical(as(m.ch.A, "matrix"), `dim<-`(ch.A@x, ch.A@Dim)))

ae1 <- function(a, b, ...) all.equal(as(a, "matrix"), as(b, "matrix"), ...)
ae2 <- function(a, b, ...) ae1(unname(a), unname(b), ...)

A ~ P1' L1 D L1' P1 ~ P1' L L' P1 in floating point
stopifnot(exprs = {
 identical(names(e.ch.A), c("P1.", "L1", "D", "L1.", "P1"))
 identical(names(E.ch.A), c("P1.", "L", "L.", "P1"))
 identical(e.ch.A[["P1"]],
 new("pMatrix", Dim = c(n, n), Dimnames = c(list(NULL), dn[2L]),
 margin = 2L, perm = invertPerm(ch.A@perm)))
 identical(e.ch.A[["P1."]], t(e.ch.A[["P1"]]))
 identical(e.ch.A[["L1."]], t(e.ch.A[["L1"]]))
 identical(E.ch.A[["L."]], t(E.ch.A[["L"]]))
 identical(e.ch.A[["D"]], Diagonal(x = diag(ch.A)))
 all.equal(E.ch.A[["L"]], with(e.ch.A, L1 %*% sqrt(D)))
 ae1(A, with(e.ch.A, P1. %*% L1 %*% D %*% L1. %*% P1))
 ae1(A, with(E.ch.A, P1. %*% L %*% L. %*% P1))
 ae2(A[ch.A@perm, ch.A@perm], with(e.ch.A, L1 %*% D %*% L1.))
})
```

```

 ae2(A[ch.A@perm, ch.A@perm], with(E.ch.A, L %*% L.))
 })

Factorization handled as factorized matrix
b <- rnorm(n)
all.equal(det(A), det(ch.A), tolerance = 0)
all.equal(solve(A, b), solve(ch.A, b), tolerance = 0)

For identical results, we need the _unpivoted_ factorization
computed by det(A) and solve(A, b)
(ch.A.nopivot <- Cholesky(A, perm = FALSE))
stopifnot(identical(det(A), det(ch.A.nopivot)),
 identical(solve(A, b), solve(ch.A.nopivot, b)))

```

Cholesky-methods

*Methods for Cholesky Factorization***Description**

Computes the pivoted Cholesky factorization of an  $n \times n$  real, symmetric matrix  $A$ , which has the general form

$$P_1 A P_1' = L_1 D L_1' \stackrel{D_{jj} \geq 0}{=} L L'$$

or (equivalently)

$$A = P_1' L_1 D L_1' P_1 \stackrel{D_{jj} \geq 0}{=} P_1' L L' P_1$$

where  $P_1$  is a permutation matrix,  $L_1$  is a unit lower triangular matrix,  $D$  is a diagonal matrix, and  $L = L_1 \sqrt{D}$ . The second equalities hold only for positive semidefinite  $A$ , for which the diagonal entries of  $D$  are non-negative and  $\sqrt{D}$  is well-defined.

Methods for [denseMatrix](#) are built on LAPACK routines `dpstrf`, `dpotrf`, and `dpptrf`. The latter two do not permute rows or columns, so that  $P_1$  is an identity matrix.

Methods for [sparseMatrix](#) are built on CHOLMOD routines `cholmod_analyze` and `cholmod_factorize_p`.

**Usage**

```

Cholesky(A, ...)
S4 method for signature 'dsyMatrix'
Cholesky(A, perm = TRUE, tol = -1, ...)
S4 method for signature 'dspMatrix'
Cholesky(A, ...)
S4 method for signature 'dsCMatrix'
Cholesky(A, perm = TRUE, LDL = !super, super = FALSE,
 Imult = 0, ...)
S4 method for signature 'ddiMatrix'
Cholesky(A, ...)
S4 method for signature 'generalMatrix'
Cholesky(A, uplo = "U", ...)
S4 method for signature 'triangularMatrix'
Cholesky(A, uplo = "U", ...)
S4 method for signature 'matrix'
Cholesky(A, uplo = "U", ...)

```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>A</code>     | a <a href="#">finite</a> , symmetric matrix or <a href="#">Matrix</a> to be factorized. If $A$ is square but not symmetric, then it will be <i>treated</i> as symmetric; see <code>uplo</code> . Methods for dense $A$ require positive definiteness when <code>perm = FALSE</code> and positive semidefiniteness when <code>perm = TRUE</code> . Methods for sparse $A$ require positive definiteness when <code>LDL = TRUE</code> and nonzero leading principal minors (after pivoting) when <code>LDL = FALSE</code> . Methods for sparse, <i>diagonal</i> $A$ are an exception, requiring positive semidefiniteness unconditionally. |
| <code>perm</code>  | a logical indicating if the rows and columns of $A$ should be pivoted. Methods for sparse $A$ employ the approximate minimum degree (AMD) algorithm in order to reduce fill-in, i.e., without regard for numerical stability. Pivoting for sparsity may introduce nonpositive leading principal minors, causing the factorization to fail, in which case it may be necessary to set <code>perm = FALSE</code> .                                                                                                                                                                                                                          |
| <code>tol</code>   | a <a href="#">finite</a> numeric tolerance, used only if <code>perm = TRUE</code> . The factorization algorithm stops if the pivot is less than or equal to <code>tol</code> . Negative <code>tol</code> is equivalent to <code>nrow(A) * .Machine\$double.eps * max(diag(A))</code> .                                                                                                                                                                                                                                                                                                                                                   |
| <code>LDL</code>   | a logical indicating if the simplicial factorization should be computed as $P_1' L_1 D L_1' P_1$ , such that the result stores the lower triangular entries of $L_1 - I + D$ . The alternative is $P_1' L L' P_1$ , such that the result stores the lower triangular entries of $L = L_1 \sqrt{D}$ . This argument is ignored if <code>super = TRUE</code> (or if <code>super = NA</code> and the supernodal algorithm is chosen), as the supernodal code does not yet support the <code>LDL = TRUE</code> variant.                                                                                                                      |
| <code>super</code> | a logical indicating if the factorization should use the supernodal algorithm. The alternative is the simplicial algorithm. Setting <code>super = NA</code> leaves the choice to a CHOLMOD-internal heuristic.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>Imult</code> | a <a href="#">finite</a> number. The matrix that is factorized is $A + \text{Imult} * \text{diag}(\text{nrow}(A))$ , i.e., $A$ plus <code>Imult</code> times the identity matrix. This argument is useful for symmetric, indefinite $A$ , as <code>Imult &gt; max(rowSums(abs(A)) - diag(abs(A)))</code> ensures that $A + \text{Imult} * \text{diag}(\text{nrow}(A))$ is diagonally dominant. (Symmetric, diagonally dominant matrices are positive definite.)                                                                                                                                                                          |
| <code>uplo</code>  | a string, either "U" or "L", indicating which triangle of $A$ should be used to compute the factorization. The default is "U", even for lower triangular $A$ , to be consistent with <a href="#">chol</a> from <a href="#">base</a> .                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>...</code>   | further arguments passed to or from methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Details**

Note that the result of a call to `Cholesky` inherits from [CholeskyFactorization](#) but not [Matrix](#). Users who just want a matrix should consider using [chol](#), whose methods are simple wrappers around `Cholesky` returning just the upper triangular Cholesky factor  $L'$ , typically as a [triangularMatrix](#). However, a more principled approach would be to construct factors as needed from the `CholeskyFactorization` object, e.g., with `expand1(x, "L")`, if  $x$  is the object.

The behaviour of `Cholesky(A, perm = TRUE)` for dense  $A$  is somewhat exceptional, in that it expects *without* checking that  $A$  is positive semidefinite. By construction, if  $A$  is positive semidefinite and the exact algorithm encounters a zero pivot, then the unfactorized trailing submatrix is the zero matrix, and there is nothing left to do. Hence when the finite precision algorithm encounters a pivot less than `tol`, it signals a warning instead of an error and zeros the trailing submatrix in order to guarantee that  $P' L L' P$  is positive semidefinite even if  $A$  is not. It follows that one way to test for

positive semidefiniteness of  $A$  in the event of a warning is to analyze the error

$$\frac{\|A - P'LL'P\|}{\|A\|}.$$

See the examples and LAPACK Working Note (“LAWN”) 161 for details.

### Value

An object representing the factorization, inheriting from virtual class `CholeskyFactorization`. For a traditional matrix  $A$ , the specific class is `Cholesky`. For  $A$  inheriting from `unpackedMatrix`, `packedMatrix`, and `sparseMatrix`, the specific class is `Cholesky`, `pCholesky`, and `dCHMsimpl` or `dCHMsupper`, respectively.

### See Also

Classes `Cholesky`, `pCholesky`, `dCHMsimpl` and `dCHMsupper` and their methods.

Classes `dpoMatrix`, `dppMatrix`, and `dsCMatrix`.

Generic function `chol`, for obtaining the upper triangular Cholesky factor  $L'$  as a matrix or `Matrix`.

Generic functions `expand1` and `expand2`, for constructing matrix factors from the result.

Generic functions `BunchKaufman`, `Schur`, `lu`, and `qr`, for computing other factorizations.

### Examples

```
showMethods("Cholesky", inherited = FALSE)
set.seed(0)

---- Dense -----

.... Positive definite

n <- 6L
(A1 <- crossprod(Matrix(rnorm(n * n), n, n)))
(ch.A1.nopivot <- Cholesky(A1, perm = FALSE))
```

```

(ch.A1 <- Cholesky(A1))
stopifnot(exprs = {
 length(ch.A1@perm) == ncol(A1)
 isPerm(ch.A1@perm)
 is.unsorted(ch.A1@perm) # typically not the identity permutation
 length(ch.A1@nopivot@perm) == 0L
})

A ~ P1' L D L' P1 ~ P1' L L' P1 in floating point
str(e.ch.A1 <- expand2(ch.A1, LDL = TRUE), max.level = 2L)
str(E.ch.A1 <- expand2(ch.A1, LDL = FALSE), max.level = 2L)
stopifnot(exprs = {
 all.equal(as(A1, "matrix"), as(Reduce(`%*%`, e.ch.A1), "matrix"))
 all.equal(as(A1, "matrix"), as(Reduce(`%*%`, E.ch.A1), "matrix"))
})

.... Positive semidefinite but not positive definite

A2 <- A1
A2[1L,] <- A2[, 1L] <- 0
A2
try(Cholesky(A2, perm = FALSE)) # fails as not positive definite
ch.A2 <- Cholesky(A2) # returns, with a warning and ...
A2.hat <- Reduce(`%*%`, expand2(ch.A2, LDL = FALSE))
norm(A2 - A2.hat, "2") / norm(A2, "2") # 7.670858e-17

.... Not positive semidefinite

A3 <- A1
A3[1L,] <- A3[, 1L] <- -1
A3
try(Cholesky(A3, perm = FALSE)) # fails as not positive definite
ch.A3 <- Cholesky(A3) # returns, with a warning and ...
A3.hat <- Reduce(`%*%`, expand2(ch.A3, LDL = FALSE))
norm(A3 - A3.hat, "2") / norm(A3, "2") # 1.781568

Indeed, 'A3' is not positive semidefinite, but 'A3.hat' _is_
ch.A3.hat <- Cholesky(A3.hat)
A3.hat.hat <- Reduce(`%*%`, expand2(ch.A3.hat, LDL = FALSE))
norm(A3.hat - A3.hat.hat, "2") / norm(A3.hat, "2") # 1.777944e-16

---- Sparse -----

Really just three cases modulo permutation :
##
type factorization minors of P1 A P1'
1 simplicial P1 A P1' = L1 D L1' nonzero
2 simplicial P1 A P1' = L L ' positive
3 supernodal P1 A P2' = L L ' positive

data(KNex, package = "Matrix")
A4 <- crossprod(KNex[["mm"]])

ch.A4 <-
list(pivoted =
 list(simpl1 = Cholesky(A4, perm = TRUE, super = FALSE, LDL = TRUE),
 simpl0 = Cholesky(A4, perm = TRUE, super = FALSE, LDL = FALSE),

```

```

 super0 = Cholesky(A4, perm = TRUE, super = TRUE)),
 unpivoted =
 list(simpl1 = Cholesky(A4, perm = FALSE, super = FALSE, LDL = TRUE),
 simpl0 = Cholesky(A4, perm = FALSE, super = FALSE, LDL = FALSE),
 super0 = Cholesky(A4, perm = FALSE, super = TRUE)))
ch.A4

s <- simplify2array
rapply2 <- function(object, f, ...) rapply(object, f, , , how = "list", ...)

s(rapply2(ch.A4, isLDL))
s(m.ch.A4 <- rapply2(ch.A4, expand1, "L")) # giving L = L1 sqrt(D)

By design, the pivoted and simplicial factorizations
are more sparse than the unpivoted and supernodal ones ...
s(rapply2(m.ch.A4, object.size))

Which is nicely visualized by lattice-based methods for 'image'
inm <- c("pivoted", "unpivoted")
jnm <- c("simpl1", "simpl0", "super0")
for(i in 1:2)
 for(j in 1:3)
 print(image(m.ch.A4[[c(i, j)]]), main = paste(inm[i], jnm[j])),
 split = c(j, i, 3L, 2L), more = i * j < 6L)

simpl1 <- ch.A4[[c("pivoted", "simpl1")]]
stopifnot(exprs = {
 length(simpl1@perm) == ncol(A4)
 isPerm(simpl1@perm, 0L)
 is.unsorted(simpl1@perm) # typically not the identity permutation
})

One can expand with and without D regardless of isLDL(.),
but "without" requires L = L1 sqrt(D), which is conditional
on min(diag(D)) >= 0, hence "with" is the default
isLDL(simpl1)
stopifnot(min(diag(simpl1)) >= 0)
str(e.ch.A4 <- expand2(simpl1, LDL = TRUE), max.level = 2L) # default
str(E.ch.A4 <- expand2(simpl1, LDL = FALSE), max.level = 2L)
stopifnot(exprs = {
 all.equal(E.ch.A4[["L"]], e.ch.A4[["L1"]] %*% sqrt(e.ch.A4[["D"]]))
 all.equal(E.ch.A4[["L."]], sqrt(e.ch.A4[["D"]]) %*% e.ch.A4[["L1."]])
 all.equal(A4, as(Reduce(`%*%`, e.ch.A4), "symmetricMatrix"))
 all.equal(A4, as(Reduce(`%*%`, E.ch.A4), "symmetricMatrix"))
})

The "same" permutation matrix with "alternate" representation
[i, perm[i]] {margin=1} <-> [invertPerm(perm)[j], j] {margin=2}
alt <- function(P) {
 P@margin <- 1L + !(P@margin - 1L) # 1 <-> 2
 P@perm <- invertPerm(P@perm)
 P
}

Expansions are elegant but inefficient (transposes are redundant)
hence programmers should consider methods for 'expand1' and 'diag'
stopifnot(exprs = {

```

```

 identical(expand1(simpl1, "P1"), alt(e.ch.A4[["P1"]]))
 identical(expand1(simpl1, "L"), E.ch.A4[["L"]])
 identical(Diagonal(x = diag(simpl1)), e.ch.A4[["D"]])
 })

chol(A, pivot = value) is a simple wrapper around
Cholesky(A, perm = value, LDL = FALSE, super = FALSE),
returning L' = sqrt(D) L1' _but_ giving no information
about the permutation P1
selectMethod("chol", "dsCMatrix")
stopifnot(all.equal(chol(A4, pivot = TRUE), E.ch.A4[["L."]]))

Now a symmetric matrix with positive _and_ negative eigenvalues,
hence _not_ positive semidefinite
A5 <- new("dsCMatrix",
 Dim = c(7L, 7L),
 p = c(0:1, 3L, 6:7, 10:11, 15L),
 i = c(0L, 0:1, 0:3, 2:5, 3:6),
 x = c(1, 6, 38, 10, 60, 103, -4, 6, -32, -247, -2, -16, -128, -2, -67))
(ev <- eigen(A5, only.values = TRUE)$values)
(t.ev <- table(factor(sign(ev), -1:1))) # the matrix "inertia"

ch.A5 <- Cholesky(A5)
isLDL(ch.A5)
(d.A5 <- diag(ch.A5)) # diag(D) is partly negative

Sylvester's law of inertia holds here, but not in general
in finite precision arithmetic
stopifnot(identical(table(factor(sign(d.A5), -1:1)), t.ev))

try(expand1(ch.A5, "L")) # unable to compute L = L1 sqrt(D)
try(expand2(ch.A5, LDL = FALSE)) # ditto
try(chol(A5, pivot = TRUE)) # ditto

The default expansion is "square root free" and still works here
str(e.ch.A5 <- expand2(ch.A5, LDL = TRUE), max.level = 2L)
stopifnot(all.equal(A5, as(Reduce("%*%", e.ch.A5), "symmetricMatrix")))

Version of the SuiteSparse library, which includes CHOLMOD
Mv <- Matrix.Version()
Mv[["suitesparse"]]

```

---

coerce-methods-graph    *Conversions "graph" <-> (sparse) Matrix*

---

## Description

Since 2005, package **Matrix** has supported coercions to and from class **graph** from package **graph**. Since 2013, this functionality has been exposed via functions **T2graph** and **graph2T**, which, unlike methods for **as**(from, "<Class>"), support optional arguments.

## Usage

```

graph2T(from, use.weights =)
T2graph(from, need.uniq = !isUniqueT(from), edgemode = NULL)

```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| from        | for graph2T(), an R object of class "graph";<br>for T2graph(), a sparse matrix inheriting from "TsparseMatrix".                                                                                                                                                                                                                           |
| use.weights | logical indicating if weights should be used, i.e., equivalently the result will be numeric, i.e. of class <b>dgTMatrix</b> ; otherwise the result will be <b>ngTMatrix</b> or <b>nsTMatrix</b> , the latter if the graph is undirected. The default looks if there are weights in the graph, and if any differ from 1, weights are used. |
| need.uniq   | a logical indicating if from may need to be internally "uniqified"; do not set this and hence rather use the default, unless you know what you are doing!                                                                                                                                                                                 |
| edgemode    | one of NULL, "directed", or "undirected". The default NULL looks if the matrix is symmetric and assumes "undirected" in that case.                                                                                                                                                                                                        |

**Value**

For graph2T(), a sparse matrix inheriting from "TsparseMatrix".

For T2graph() an R object of class "graph".

**See Also**

Package **igraph**, which provides similar coercions to and from its class **igraph** via functions `graph_from_adjacency_matrix` and `as_adjacency_matrix`.

**Examples**

```
if(requireNamespace("graph")) {
 n4 <- LETTERS[1:4]; dns <- list(n4,n4)
 show(a1 <- sparseMatrix(i= c(1:4), j=c(2:4,1), x = 2, dimnames=dns))
 show(g1 <- as(a1, "graph")) # directed
 unlist(graph::edgeWeights(g1)) # all '2'

 show(a2 <- sparseMatrix(i= c(1:4,4), j=c(2:4,1:2), x = TRUE, dimnames=dns))
 show(g2 <- as(a2, "graph")) # directed
 # now if you want it undirected:
 show(g3 <- T2graph(as(a2,"TsparseMatrix"), edgemode="undirected"))
 show(m3 <- as(g3,"Matrix"))
 show(graph2T(g3)) # a "pattern Matrix" (nsTMatrix)

 a. <- sparseMatrix(i=4:1, j=1:4, dimnames=list(n4, n4), repr="T") # no 'x'
 show(a.) # "ngTMatrix"
 show(g. <- as(a., "graph"))

}
```

## Description

Methods for coercion from and to sparse matrices from package **SparseM** are provided here, for ease of porting functionality to the **Matrix** package, and comparing functionality of the two packages. All these work via the usual `as(, "<class>")` coercion,

```
as(from, Class)
```

## Methods

```
from = "matrix.csr", to = "dgRMatrix" ...
from = "matrix.csc", to = "dgCMatrix" ...
from = "matrix.coo", to = "dgTMatrix" ...
from = "dgRMatrix", to = "matrix.csr" ...
from = "dgCMatrix", to = "matrix.csc" ...
from = "dgTMatrix", to = "matrix.coo" ...
from = "Matrix", to = "matrix.csr" ...
from = "matrix.csr", to = "dgCMatrix" ...
from = "matrix.coo", to = "dgCMatrix" ...
from = "matrix.csr", to = "Matrix" ...
from = "matrix.csc", to = "Matrix" ...
from = "matrix.coo", to = "Matrix" ...
```

---

colSums-methods

*Form Row and Column Sums and Means*

---

## Description

Form row and column sums and means for objects, for [sparseMatrix](#) the result may optionally be sparse ([sparseVector](#)), too. Row or column names are kept respectively as for **base** matrices and [colSums](#) methods, when the result is [numeric](#) vector.

## Usage

```
colSums(x, na.rm = FALSE, dims = 1L, ...)
rowSums(x, na.rm = FALSE, dims = 1L, ...)
colMeans(x, na.rm = FALSE, dims = 1L, ...)
rowMeans(x, na.rm = FALSE, dims = 1L, ...)

S4 method for signature 'CsparseMatrix'
colSums(x, na.rm = FALSE, dims = 1L,
 sparseResult = FALSE, ...)
S4 method for signature 'CsparseMatrix'
rowSums(x, na.rm = FALSE, dims = 1L,
```

```

 sparseResult = FALSE, ...)
S4 method for signature 'CsparseMatrix'
colMeans(x, na.rm = FALSE, dims = 1L,
 sparseResult = FALSE, ...)
S4 method for signature 'CsparseMatrix'
rowMeans(x, na.rm = FALSE, dims = 1L,
 sparseResult = FALSE, ...)

```

### Arguments

|                           |                                                                                                                                                                                                            |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | a Matrix, i.e., inheriting from <a href="#">Matrix</a> .                                                                                                                                                   |
| <code>na.rm</code>        | logical. Should missing values (including NaN) be omitted from the calculations?                                                                                                                           |
| <code>dims</code>         | completely ignored by the Matrix methods.                                                                                                                                                                  |
| <code>...</code>          | potentially further arguments, for method <=> generic compatibility.                                                                                                                                       |
| <code>sparseResult</code> | logical indicating if the result should be sparse, i.e., inheriting from class <a href="#">sparseVector</a> . Only applicable when <code>x</code> is inheriting from a <a href="#">sparseMatrix</a> class. |

### Value

returns a numeric vector if `sparseResult` is FALSE as per default. Otherwise, returns a [sparseVector](#).

`dimnames(x)` are only kept (as `names(v)`) when the resulting `v` is [numeric](#), since [sparseVectors](#) do not have names.

### See Also

[colSums](#) and the [sparseVector](#) classes.

### Examples

```

(M <- bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))) # 7 x 8
colSums(M)
d <- Diagonal(10, c(0,0,10,0,0,2,rep(0,5)))
MM <- kronecker(d, M)
dim(MM) # 70 80
length(MM@x) # 160, but many are '0' ; drop those:
MM <- drop0(MM)
length(MM@x) # 32
cm <- colSums(MM)
(scm <- colSums(MM, sparseResult = TRUE))
stopifnot(is(scm, "sparseVector"),
 identical(cm, as.numeric(scm)))
rowSums(MM, sparseResult = TRUE) # 14 of 70 are not zero
colMeans(MM, sparseResult = TRUE) # 16 of 80 are not zero
Since we have no 'NA's, these two are equivalent :
stopifnot(identical(rowMeans(MM, sparseResult = TRUE),
 rowMeans(MM, sparseResult = TRUE, na.rm = TRUE)),
 rowMeans(Diagonal(16)) == 1/16,
 colSums(Diagonal(7)) == 1)

dimnames(x) --> names(<value>) :
dimnames(M) <- list(paste0("r", 1:7), paste0("V",1:8))
M

```

```
colSums(M)
rowMeans(M)
Assertions :
stopifnot(exprs = {
 all.equal(colSums(M),
 structure(c(1,1,6,6,6,6,3,2), names = colnames(M)))
 all.equal(rowMeans(M),
 structure(c(1,1,4,8,12,3,2)/8, names = paste0("r", 1:7)))
})
```

---

|         |                                                                            |
|---------|----------------------------------------------------------------------------|
| condest | <i>Compute Approximate CONDition number and 1-Norm of (Large) Matrices</i> |
|---------|----------------------------------------------------------------------------|

---

## Description

“Estimate”, i.e. compute approximately the CONDition number of a (potentially large, often sparse) matrix  $A$ . It works by apply a fast *randomized* approximation of the 1-norm, `norm(A, "1")`, through `onenormest(.)`.

## Usage

```
condest(A, t = min(n, 5), normA = norm(A, "1"),
 silent = FALSE, quiet = TRUE)

onenormest(A, t = min(n, 5), A.x, At.x, n,
 silent = FALSE, quiet = silent,
 iter.max = 10, eps = 4 * .Machine$double.eps)
```

## Arguments

|                        |                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>A</code>         | a square matrix, optional for <code>onenormest()</code> , where instead of $A$ , $A.x$ and $At.x$ can be specified, see there. |
| <code>t</code>         | number of columns to use in the iterations.                                                                                    |
| <code>normA</code>     | number; (an estimate of) the 1-norm of $A$ , by default <code>norm(A, "1")</code> ; may be replaced by an estimate.            |
| <code>silent</code>    | logical indicating if warning and (by default) convergence messages should be displayed.                                       |
| <code>quiet</code>     | logical indicating if convergence messages should be displayed.                                                                |
| <code>A.x, At.x</code> | when $A$ is missing, these two must be given as functions which compute $A \% x$ , or $t(A) \% x$ , respectively.              |
| <code>n</code>         | <code>== nrow(A)</code> , only needed when $A$ is not specified.                                                               |
| <code>iter.max</code>  | maximal number of iterations for the 1-norm estimator.                                                                         |
| <code>eps</code>       | the relative change that is deemed irrelevant.                                                                                 |

## Details

`condest()` calls `lu(A)`, and subsequently `onenormest(A.x = , At.x = )` to compute an approximate norm of the *inverse* of  $A$ ,  $A^{-1}$ , in a way which keeps using sparse matrices efficiently when  $A$  is sparse.

Note that `onenormest()` uses random vectors and hence *both* functions' results are random, i.e., depend on the random seed, see, e.g., `set.seed()`.

**Value**

Both functions return a [list](#); `condest()` with components,

`est`            a number  $> 0$ , the estimated (1-norm) condition number  $\hat{\kappa}$ ; when  $r := \text{rcond}(A)$ ,  $1/\hat{\kappa} \approx r$ .

`v`            the maximal  $Ax$  column, scaled to  $\text{norm}(v) = 1$ . Consequently,  $\text{norm}(Av) = \text{norm}(A)/\text{est}$ ; when `est` is large, `v` is an approximate null vector.

The function `onenormest()` returns a list with components,

`est`            a number  $> 0$ , the estimated  $\text{norm}(A, "1")$ .

`v`            0-1 integer vector length `n`, with an 1 at the index `j` with maximal column  $A[, j]$  in  $A$ .

`w`            numeric vector, the largest  $Ax$  found.

`iter`          the number of iterations used.

**Author(s)**

This is based on octave's `condest()` and `onenormest()` implementations with original author Jason Riedy, U Berkeley; translation to R and adaption by Martin Maechler.

|---------------------|---------------------------------------------------------------------------|
| CsparseMatrix-class | <i>Class "CsparseMatrix" of Sparse Matrices in Column-compressed Form</i> |
|---------------------|---------------------------------------------------------------------------|

---

## Description

The "CsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed column-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("CsparseMatrix")` for its subclasses.

## Slots

- i:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the *0-based* row numbers for each non-zero element in the matrix, i.e., `i` must be in `0:(nrow(.)-1)`.
- p:** `integer` vector for providing pointers, one for each column, to the initial (zero-based) index of elements in the column. `.@p` is of length `ncol(.) + 1`, with `p[1] == 0` and `p[length(p)] == nnzero`, such that in fact, `diff(.@p)` are the number of non-zero elements for each column. In other words, `m@p[1:ncol(m)]` contains the indices of those elements in `m@x` that are the first elements in the respective column of `m`.

**Dim, Dimnames:** inherited from the superclass, see the `sparseMatrix` class.

## Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

## Methods

matrix products `%*%`, `crossprod()` and `tcrossprod()`, several `solve` methods, and other matrix methods available:

t signature(x = "CsparseMatrix"): ...
tril signature(x = "CsparseMatrix"): ...
triu signature(x = "CsparseMatrix"): ...
```

### Note

All classes extending `CsparseMatrix` have a common validity (see [validObject](#)) check function. That function additionally checks the `i` slot for each column to contain increasing row numbers. In earlier versions of **Matrix** ( $\leq 0.999375-16$ ), [validObject](#) automatically re-sorted the entries when necessary, and hence `new()` calls with somewhat permuted `i` and `x` slots worked, as `new(...)` (with slot arguments) automatically checks the validity.

Now, you have to use [sparseMatrix](#) to achieve the same functionality or know how to use `.validateCsparse()` to do so.

### See Also

---

### Description

This is the virtual class of all dense numeric (i.e., **double**, hence “*ddense*”) S4 matrices. Its most important subclass is the [dgeMatrix](#) class.

### Extends

Class “`dMatrix`” directly; class “`Matrix`”, by the above.

### Slots

the same slots at its subclass [dgeMatrix](#), see there.

### Methods

Most methods are implemented via `as(*, "generalMatrix")` and are mainly used as “fallbacks” when the subclass doesn’t need its own specialized method.

Use [showMethods](#)(class = “`ddenseMatrix`”, where = “`package:Matrix`”) for an overview.

**See Also**

The virtual classes [Matrix](#), [dMatrix](#), and [dsparseMatrix](#).

**Examples**

```
showClass("ddenseMatrix")

showMethods(class = "ddenseMatrix", where = "package:Matrix")
```

---

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| ddiMatrix-class | <i>Class "ddiMatrix" of Diagonal Numeric Matrices</i> |
|-----------------|-------------------------------------------------------|

---

**Description**

The class "ddiMatrix" of numerical diagonal matrices. Note that diagonal matrices now extend [sparseMatrix](#), whereas they did extend dense matrices earlier.

**Objects from the Class**

Objects can be created by calls of the form `new("ddiMatrix", ...)` but typically rather via [Diagonal](#).

**Slots**

**x:** numeric vector. For an  $n \times n$  matrix, the x slot is of length  $n$  or  $\emptyset$ , depending on the diag slot:  
**diag:** "character" string, either "U" or "N" where "U" denotes unit-diagonal, i.e., identity matrices.  
**Dim,Dimnames:** matrix dimension and [dimnames](#), see the [Matrix](#) class description.

**Extends**

Class "[diagonalMatrix](#)", directly. Class "[dMatrix](#)", directly. Class "[sparseMatrix](#)", indirectly, see `showClass("ddiMatrix")`.

**Methods**

```
%*% signature(x = "ddiMatrix", y = "ddiMatrix"): ...
```

**See Also**

Class [diagonalMatrix](#) and function [Diagonal](#).

**Examples**

```
(d2 <- Diagonal(x = c(10,1)))
str(d2)
slightly larger in internal size:
str(as(d2, "sparseMatrix"))

M <- Matrix(cbind(1,2:4))
M %*% d2 #> `fast' multiplication
```

```
chol(d2) # trivial
stopifnot(is(cd2 <- chol(d2), "ddiMatrix"),
 all.equal(cd2@x, c(sqrt(10),1)))
```

denseLU-class

*Dense LU Factorizations*

## Description

denseLU is the class of dense, row-pivoted LU factorizations of  $m \times n$  real matrices  $A$ , having the general form

$$P_1 A = LU$$

or (equivalently)

$$A = P_1' LU$$

where  $P_1$  is an  $m \times m$  permutation matrix,  $L$  is an  $m \times \min(m, n)$  unit lower trapezoidal matrix, and  $U$  is a  $\min(m, n) \times n$  upper trapezoidal matrix. If  $m = n$ , then the factors  $L$  and  $U$  are triangular.

## Slots

Dim, Dimnames inherited from virtual class [MatrixFactorization](#).

x a numeric vector of length `prod(Dim)` storing the triangular  $L$  and  $U$  factors together in a packed format. The details of the representation are specified by the manual for LAPACK routine `dgetrf`.

perm an integer vector of length `min(Dim)` specifying the permutation  $P_1$  as a product of transpositions. The corresponding permutation vector can be obtained as `asPerm(perm)`.

## Extends

Class [LU](#), directly. Class [MatrixFactorization](#), by class [LU](#), distance 2.

## Instantiation

Objects can be generated directly by calls of the form `new("denseLU", ...)`, but they are more typically obtained as the value of `lu(x)` for  $x$  inheriting from [denseMatrix](#) (often [dgeMatrix](#)).

## Methods

`coerce` signature(`from` = "denseLU", `to` = "dgeMatrix"): returns a [dgeMatrix](#) with the dimensions of the factorized matrix  $A$ , equal to  $L$  below the diagonal and equal to  $U$  on and above the diagonal.

`determinant` signature(`from` = "denseLU", `logarithm` = "logical"): computes the determinant of the factorized matrix  $A$  or its logarithm.

`expand` signature(`x` = "denseLU"): see [expand-methods](#).

`expand1` signature(`x` = "denseLU"): see [expand1-methods](#).

`expand2` signature(`x` = "denseLU"): see [expand2-methods](#).

`solve` signature(`a` = "denseLU", `b` = "missing"): see [solve-methods](#).

## Examples

```
showClass("denseLU")
set.seed(1)

n <- 3L
(A <- Matrix(round(rnorm(n * n), 2L), n, n))

With dimnames, to see that they are propagated :
dimnames(A) <- dn <- list(paste0("r", seq_len(n)),
 paste0("c", seq_len(n)))

(lu.A <- lu(A))
str(e.lu.A <- expand2(lu.A), max.level = 2L)

Underlying LAPACK representation
(m.lu.A <- as(lu.A, "dgeMatrix")) # which is L and U interlaced
stopifnot(identical(as(m.lu.A, "matrix"), `dim<-`(lu.A@x, lu.A@Dim)))

ae1 <- function(a, b, ...) all.equal(as(a, "matrix"), as(b, "matrix"), ...)
ae2 <- function(a, b, ...) ae1(unname(a), unname(b), ...)

A ~ P1' L U in floating point
stopifnot(exprs = {
 identical(names(e.lu.A), c("P1.", "L", "U"))
 identical(e.lu.A[["P1."]],
 new("pMatrix", Dim = c(n, n), Dimnames = c(dn[1L], list(NULL)),
 margin = 1L, perm = invertPerm(asPerm(lu.A@perm)))
 identical(e.lu.A[["L"]],
 new("dtrMatrix", Dim = c(n, n), Dimnames = list(NULL, NULL),
 uplo = "L", diag = "U", x = lu.A@x))
 identical(e.lu.A[["U"]],
 new("dtrMatrix", Dim = c(n, n), Dimnames = c(list(NULL), dn[2L]),
 uplo = "U", diag = "N", x = lu.A@x))
 ae1(A, with(e.lu.A, P1. %*% L %*% U))
 ae2(A[asPerm(lu.A@perm),], with(e.lu.A, L %*% U))
})

Factorization handled as factorized matrix
b <- rnorm(n)
stopifnot(identical(det(A), det(lu.A)),
 identical(solve(A, b), solve(lu.A, b)))
```

|-------------------|----------------------------------------------------------|
| denseMatrix-class | <i>Virtual Class "denseMatrix" of All Dense Matrices</i> |
|-------------------|----------------------------------------------------------|

---

### Description

This is the virtual class of all dense (S4) matrices. It partitions into two subclasses [packedMatrix](#) and [unpackedMatrix](#). Alternatively into the (currently) three subclasses [ddenseMatrix](#), [ldenseMatrix](#), and [ndenseMatrix](#).

`denseMatrix` is (hence) the direct superclass of these ( $2 + 3 = 5$ ) classes.

### Extends

class "Matrix" directly.

### Slots

exactly those of its superclass "[Matrix](#)", i.e., "Dim" and "Dimnames".

### Methods

Use [showMethods](#)(class = "denseMatrix", where = "package:Matrix") for an overview of methods.

Extraction ("[\[](#)") methods, see [\[-methods](#).

### See Also

[colSums](#), [kronecker](#), and other such methods with own help pages.

Its superclass [Matrix](#), and main subclasses, [ddenseMatrix](#) and [sparseMatrix](#).

### Examples

```
showClass("denseMatrix")
```

---

|                 |                                                             |
|-----------------|-------------------------------------------------------------|
| dgCMatrix-class | <i>Compressed, sparse, column-oriented numeric matrices</i> |
|-----------------|-------------------------------------------------------------|

---

### Description

The `dgCMatrix` class is a class of sparse numeric matrices in the compressed, sparse, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. `dgCMatrix` is the "*standard*" class for sparse numeric matrices in the **Matrix** package.

### Objects from the Class

Objects can be created by calls of the form `new("dgCMatrix", ...)`, more typically via `as(*, "CsparseMatrix")` or similar. Often however, more easily via [Matrix](#)(\*, sparse = TRUE), or most efficiently via [sparseMatrix](#)() .

**Slots**

**x:** Object of class "numeric" - the non-zero elements of the matrix.  
**...** all other slots are inherited from the superclass "[CsparseMatrix](#)".

**Methods**

Matrix products (e.g., [crossprod-methods](#)), and (among other)

**coerce** signature(from = "matrix", to = "dgCMatrix")

**diag** signature(x = "dgCMatrix"): returns the diagonal of x

**dim** signature(x = "dgCMatrix"): returns the dimensions of x

**image** signature(x = "dgCMatrix"): plots an image of x using the [levelplot](#) function

**solve** signature(a = "dgCMatrix", b = "..."): see [solve-methods](#), notably the extra argument sparse.

**lu** signature(x = "dgCMatrix"): computes the LU decomposition of a square dgCMatrix object

**See Also**

Classes [dsCMatrix](#), [dtCMatrix](#), [lu](#)

**Examples**

```
(m <- Matrix(c(0,0,2:0), 3,5))
str(m)
m[,1]
```

---

dgeMatrix-class

---

Class "dgeMatrix" of Dense Numeric (S4 Class) Matrices

---

**Description**

A general numeric dense matrix in the S4 Matrix representation. dgeMatrix is the "standard" class for dense numeric matrices in the **Matrix** package.

**Objects from the Class**

Objects can be created by calls of the form `new("dgeMatrix", ...)` or, more commonly, by coercion from the Matrix class (see [Matrix](#)) or by [Matrix\(...\)](#).

**Slots**

**x:** Object of class "numeric" - the numeric values contained in the matrix, in column-major order.

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** a list of length two - inherited from class [Matrix](#).

**factors:** Object of class "list" - a list of factorizations of the matrix.

## Methods

The are group methods (see, e.g., [Arith](#))

**Arith** signature(e1 = "dgeMatrix", e2 = "dgeMatrix"): ...

**Arith** signature(e1 = "dgeMatrix", e2 = "numeric"): ...

**Arith** signature(e1 = "numeric", e2 = "dgeMatrix"): ...

**Math** signature(x = "dgeMatrix"): ...

**Math2** signature(x = "dgeMatrix", digits = "numeric"): ...

matrix products `%*%`, [crossprod\(\)](#) and `tcrossprod()`, several [solve](#) methods, and other matrix methods available:

**Schur** signature(x = "dgeMatrix", vectors = "logical"): ...

**Schur** signature(x = "dgeMatrix", vectors = "missing"): ...

**chol** signature(x = "dgeMatrix"): see [chol](#).

**colMeans** signature(x = "dgeMatrix"): columnwise means (averages)

**colSums** signature(x = "dgeMatrix"): columnwise sums

**diag** signature(x = "dgeMatrix"): ...

**dim** signature(x = "dgeMatrix"): ...

**dimnames** signature(x = "dgeMatrix"): ...

**eigen** signature(x = "dgeMatrix", only.values = "logical"): ...

**eigen** signature(x = "dgeMatrix", only.values = "missing"): ...

**norm** signature(x = "dgeMatrix", type = "character"): ...

**norm** signature(x = "dgeMatrix", type = "missing"): ...

**rcond** signature(x = "dgeMatrix", norm = "character") or norm = "missing": the reciprocal condition number, [rcond\(\)](#).

**rowMeans** signature(x = "dgeMatrix"): rowwise means (averages)

**rowSums** signature(x = "dgeMatrix"): rowwise sums

**t** signature(x = "dgeMatrix"): matrix transpose

## See Also

Classes [Matrix](#), [dtrMatrix](#), and [dsyMatrix](#).

---

dgRMatrix-class

*Sparse Compressed, Row-oriented Numeric Matrices*

---

## Description

The `dgRMatrix` class is a class of sparse numeric matrices in the compressed, sparse, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Note:** The column-oriented sparse classes, e.g., [dgCMatrix](#), are preferred and better supported in the **Matrix** package.

## Objects from the Class

Objects can be created by calls of the form `new("dgRMatrix", ...)`.

## Slots

**j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each non-zero element in the matrix.

**p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**x**: Object of class "numeric" - the non-zero elements of the matrix.

**Dim**: Object of class "integer" - the dimensions of the matrix.

## Methods

**diag** signature(`x = "dgRMatrix"`): returns the diagonal of `x`

**dim** signature(`x = "dgRMatrix"`): returns the dimensions of `x`

**image** signature(`x = "dgRMatrix"`): plots an image of `x` using the [levelplot](#) function

## See Also

the [RsparseMatrix](#) class, the virtual class of all sparse compressed row-oriented matrices, with its methods. The [dgCMatrix](#) class (column compressed sparse) is really preferred.

---

 dgTMatrix-class

*Sparse matrices in triplet form*

---

## Description

The "dgTMatrix" class is the class of sparse matrices stored as (possibly redundant) triplets. The internal representation is not at all unique, contrary to the one for class [dgCMatrix](#).

## Objects from the Class

Objects can be created by calls of the form `new("dgTMatrix", ...)`, but more typically via [spMatrix\(\)](#) or [sparseMatrix\(\\*, repr = "T"\)](#).

## Slots

**i**: [integer](#) row indices of non-zero entries *in 0-base*, i.e., must be in  $0:(nrow(.)-1)$ .

**j**: [integer](#) column indices of non-zero entries. Must be the same length as slot `i` and *0-based* as well, i.e., in  $0:(ncol(.)-1)$ .

**x**: [numeric](#) vector - the (non-zero) entry at position  $(i, j)$ . Must be the same length as slot `i`. If an index pair occurs more than once, the corresponding values of slot `x` are added to form the element of the matrix.

**Dim**: Object of class "integer" of length 2 - the dimensions of the matrix.

**Methods**

**+** signature(e1 = "dgTMatrix", e2 = "dgTMatrix")  
**image** signature(x = "dgTMatrix"): plots an image of x using the [levelplot](#) function  
**t** signature(x = "dgTMatrix"): returns the transpose of x

**Note**

Triplet matrices are a convenient form in which to construct sparse matrices after which they can be coerced to [dgCMatrix](#) objects.

Note that both `new(.)` and [spMatrix](#) constructors for "dgTMatrix" (and other "TsparseMatrix" classes) implicitly add  $x_k$ 's that belong to identical  $(i_k, j_k)$  pairs.

However this means that a matrix typically can be stored in more than one possible "TsparseMatrix" representations. Use [asUniqueT\(\)](#) in order to ensure uniqueness of the internal representation of such a matrix.

**See Also**

Class [dgCMatrix](#) or the superclasses [dsparseMatrix](#) and [TsparseMatrix](#); [asUniqueT](#).

**Examples**

```
m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "TsparseMatrix"))
str(mT)
mT[1,]
mT[4, drop = FALSE]
stopifnot(identical(mT[lower.tri(mT)],
 m [lower.tri(m)]))
mT[lower.tri(mT,diag=TRUE)] <- 0
mT

Triplet representation with repeated (i,j) entries
adds the corresponding x's:
T2 <- new("dgTMatrix",
 i = as.integer(c(1,1,0,3,3)),
 j = as.integer(c(2,2,4,0,0)), x=10*1:5, Dim=4:5)
str(T2) # contains (i,j,x) slots exactly as above, but
T2 ## has only three non-zero entries, as for repeated (i,j)'s,
 ## the corresponding x's are "implicitly" added
stopifnot(nnzero(T2) == 3)
```

---

Diagonal

---

Construct a Diagonal Matrix

---

**Description**

Construct a formally diagonal [Matrix](#), i.e., an object inheriting from virtual class [diagonalMatrix](#) (or, if desired, a *mathematically* diagonal [CsparseMatrix](#)).

**Usage**

```

Diagonal(n, x = NULL, names = FALSE)

.sparseDiagonal(n, x = NULL, uplo = "U", shape = "t", unitri = TRUE, kind, cols)
.trDiagonal(n, x = NULL, uplo = "U", unitri = TRUE, kind)
.symDiagonal(n, x = NULL, uplo = "U", kind)

```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| n      | integer indicating the dimension of the (square) matrix. If missing, then <code>length(x)</code> is used.                                                                                                                                                                                                                                                                                                      |
| x      | numeric or logical vector listing values for the diagonal entries, to be recycled as necessary. If <code>NULL</code> (the default), then the result is a unit diagonal matrix. <code>.sparseDiagonal()</code> and friends ignore non- <code>NULL</code> <code>x</code> when <code>kind = "n"</code> .                                                                                                          |
| names  | either <code>logical</code> <code>TRUE</code> or <code>FALSE</code> or then a <code>character</code> vector of <code>length</code> <code>n</code> . If true <i>and</i> <code>names(x)</code> is not <code>NULL</code> , use that as both row and column names for the resulting matrix. When a character vector, use it for both dimnames.                                                                     |
| uplo   | one of <code>c("U", "L")</code> , specifying the uplo slot of the result if the result is formally triangular or symmetric.                                                                                                                                                                                                                                                                                    |
| shape  | one of <code>c("t", "s", "g")</code> , indicating if the result should be formally triangular, symmetric, or “general”. The result will inherit from virtual class <code>triangularMatrix</code> , <code>symmetricMatrix</code> , or <code>generalMatrix</code> , respectively.                                                                                                                                |
| unitri | logical indicating if a formally triangular result with ones on the diagonal should be formally <i>unit</i> triangular, i.e., with diag slot equal to “U” rather than “N”.                                                                                                                                                                                                                                     |
| kind   | one of <code>c("d", "l", "n")</code> , indicating the “mode” of the result: numeric, logical, or pattern. The result will inherit from virtual class <code>dsparseMatrix</code> , <code>lsparseMatrix</code> , or <code>nsparseMatrix</code> , respectively. Values other than “n” are ignored when <code>x</code> is non- <code>NULL</code> ; in that case the mode is determined by <code>typeof(x)</code> . |
| cols   | optional integer vector with values in $0:(n-1)$ , indexing columns of the specified diagonal matrix. If specified, then the result is (mathematically) $D[, cols+1]$ rather than $D$ , where $D = \text{Diagonal}(n, x)$ , and it is always “general” (i.e., shape is ignored).                                                                                                                               |

**Value**

`Diagonal()` returns an object inheriting from virtual class `diagonalMatrix`.

`.sparseDiagonal()` returns a `CsparseMatrix` representation of `Diagonal(n, x)` or, if `cols` is given, of `Diagonal(n, x)[, cols+1]`. The precise class of the result depends on `shape` and `kind`.

`.trDiagonal()` and `.symDiagonal()` are simple wrappers, for `.sparseDiagonal(shape = "t")` and `.sparseDiagonal(shape = "s")`, respectively.

`.sparseDiagonal()` exists primarily to leverage efficient C-level methods available for `CsparseMatrix`.

**Author(s)**

Martin Maechler

**See Also**

the generic function `diag` for *extraction* of the diagonal from a matrix works for all “Matrices”.

`bandSparse` constructs a *banded* sparse matrix from its non-zero sub-/super - diagonals. `band(A)` returns a band matrix containing some sub-/super - diagonals of A.

`Matrix` for general matrix construction; further, class `diagonalMatrix`.

**Examples**

```
Diagonal(3)
Diagonal(x = 10^(3:1))
Diagonal(x = (1:4) >= 2)#-> "ldiMatrix"

Use Diagonal() + kronecker() for "repeated-block" matrices:
M1 <- Matrix(0+0:5, 2,3)
(M <- kronecker(Diagonal(3), M1))

(S <- crossprod(Matrix(rbinom(60, size=1, prob=0.1), 10,6)))
(SI <- S + 10*.symDiagonal(6)) # sparse symmetric still
stopifnot(is(SI, "dsCMatrix"))
(I4 <- .sparseDiagonal(4, shape="t"))# now (2012-10) unittriangular
stopifnot(I4@diag == "U", all(I4 == diag(4)))
```

---

diagonalMatrix-class    *Class "diagonalMatrix" of Diagonal Matrices*

---

**Description**

Class "diagonalMatrix" is the virtual class of all diagonal matrices.

**Objects from the Class**

A virtual Class: No objects may be created from it.

**Slots**

**diag:** `character` string, either "U" or "N", where "U" means ‘unit-diagonal’.

**Dim:** matrix dimension, and

**Dimnames:** the `dimnames`, a `list`, see the `Matrix` class description. Typically `list(NULL, NULL)` for diagonal matrices.

**Extends**

Class "`sparseMatrix`", directly.

## Methods

These are just a subset of the signature for which defined methods. Currently, there are (too) many explicit methods defined in order to ensure efficient methods for diagonal matrices.

```
coerce signature(from = "matrix", to = "diagonalMatrix"): ...
coerce signature(from = "Matrix", to = "diagonalMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "generalMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "triangularMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "nMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "matrix"): ...
coerce signature(from = "diagonalMatrix", to = "sparseVector"): ...
t signature(x = "diagonalMatrix"): ...
 and many more methods

solve signature(a = "diagonalMatrix", b, ...): is trivially implemented, of course; see also
 solve-methods.

which signature(x = "nMatrix"), semantically equivalent to base function which(x,
 arr.ind).

"Math" signature(x = "diagonalMatrix"): all these group methods return a
 "diagonalMatrix", apart from cumsum() etc which return a vector also for base matrix.

* signature(e1 = "ddiMatrix", e2="denseMatrix"): arithmetic and other operators from the
 Ops group have a few dozen explicit method definitions, in order to keep the results diagonal
 in many cases, including the following:

/ signature(e1 = "ddiMatrix", e2="denseMatrix"): the result is from class ddiMatrix which
 is typically very desirable. Note that when e2 contains off-diagonal zeros or NAs, we implicitly
 use $0/x = 0$, hence differing from traditional R arithmetic (where $0/0 \mapsto \text{NaN}$), in order to
 preserve sparsity.

summary (object = "diagonalMatrix"): Returns an object of S3 class "diagSummary" which
 is the summary of the vector object@x plus a simple heading, and an appropriate print
 method.
```

|         |                                                                                          |
|---------|------------------------------------------------------------------------------------------|
| diagU2N | <i>Transform Triangular Matrices from Unit Triangular to General Triangular and Back</i> |
|---------|------------------------------------------------------------------------------------------|

---

## Description

Transform a triangular matrix `x`, i.e., of [class `triangularMatrix`](#), from (internally!) unit triangular (“unittriangular”) to “general” triangular (`diagU2N(x)`) or back (`diagN2U(x)`). Note that the latter, `diagN2U(x)`, also sets the diagonal to one in cases where `diag(x)` was not all one.

`.diagU2N(x)` and `.diagN2U(x)` assume *without* checking that `x` is a [triangularMatrix](#) with suitable `diag` slot (“U” and “N”, respectively), hence they should be used with care.

## Usage

```

diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)

```

```

.diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
.diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)

```

## Arguments

|                         |                                                                                                                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | a <a href="#">triangularMatrix</a> , often sparse.                                                                                                                                                  |
| <code>cl</code>         | (optional, for speedup only:) class (definition) of <code>x</code> .                                                                                                                                |
| <code>checkDense</code> | logical indicating if dense (see <a href="#">denseMatrix</a> ) matrices should be considered at all; i.e., when false, as per default, the result will be sparse even when <code>x</code> is dense. |

## Details

The concept of unit triangular matrices with a `diag` slot of “U” stems from LAPACK.

## Value

a triangular matrix of the same [class](#) but with a different `diag` slot. For `diagU2N` (semantically) with identical entries as `x`, whereas in `diagN2U(x)`, the off-diagonal entries are unchanged and the diagonal is set to all 1 even if it was not previously.

## Note

Such internal storage details should rarely be of relevance to the user. Hence, these functions really are rather *internal* utilities.

## See Also

["triangularMatrix"](#), ["dtCMatrix"](#).

## Examples

```
(T <- Diagonal(7) + triu(Matrix(rpois(49, 1/4), 7, 7), k = 1))
(uT <- diagN2U(T)) # "unitriangular"
(t.u <- diagN2U(10*T)) # changes the diagonal!
stopifnot(all(T == uT), diag(t.u) == 1,
 identical(T, diagU2N(uT)))
T[upper.tri(T)] <- 5 # still "dtC"
T <- diagN2U(as(T, "triangularMatrix"))
dT <- as(T, "denseMatrix") # (unitriangular)
dT.n <- diagU2N(dT, checkDense = TRUE)
sT.n <- diagU2N(dT)
stopifnot(is(dT.n, "denseMatrix"), is(sT.n, "sparseMatrix"),
 dT@diag == "U", dT.n@diag == "N", sT.n@diag == "N",
 all(dT == dT.n), all(dT == sT.n))
```

---

dimScale

*Scale the Rows and Columns of a Matrix*

---

## Description

dimScale, rowScale, and colScale implement  $D1 \%*\% x \%*\% D2$ ,  $D \%*\% x$ , and  $x \%*\% D$  for diagonal matrices  $D1$ ,  $D2$ , and  $D$  with diagonal entries  $d1$ ,  $d2$ , and  $d$ , respectively. Unlike the explicit products, these functions preserve `dimnames(x)` and symmetry where appropriate.

## Usage

```
dimScale(x, d1 = sqrt(1/diag(x, names = FALSE)), d2 = d1)
rowScale(x, d)
colScale(x, d)
```

## Arguments

|                                                    |                                                                                                                          |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                                     | a matrix, possibly inheriting from virtual class <a href="#">Matrix</a> .                                                |
| <code>d1</code> , <code>d2</code> , <code>d</code> | numeric vectors giving factors by which to scale the rows or columns of <code>x</code> ; they are recycled as necessary. |

## Details

`dimScale(x)` (with `d1` and `d2` unset) is only roughly equivalent to `cov2cor(x)`. `cov2cor` sets the diagonal entries of the result to 1 (exactly); `dimScale` does not.

## Value

The result of scaling `x`, currently always inheriting from virtual class [dMatrix](#).

It inherits from [triangularMatrix](#) if and only if `x` does. In the special case of `dimScale(x, d1, d2)` with identical `d1` and `d2`, it inherits from [symmetricMatrix](#) if and only if `x` does.

## Author(s)

Mikael Jagan

```

n <- 6L
(x <- forceSymmetric(matrix(1, n, n)))
dimnames(x) <- rep.int(list(letters[seq_len(n)]), 2L)

d <- seq_len(n)
(D <- Diagonal(x = d))

(scx <- dimScale(x, d)) # symmetry and 'dimnames' kept
(mmx <- D %*% x %*% D) # symmetry and 'dimnames' lost
stopifnot(identical(unname(as(scx, "generalMatrix")), mmx))

rowScale(x, d)
colScale(x, d)

```

dMatrix-class

*(Virtual) Class "dMatrix" of "double" Matrices***Description**

The dMatrix class is a virtual class contained by all actual classes of numeric matrices in the **Matrix** package. Similarly, all the actual classes of logical matrices inherit from the lMatrix class.

**Slots**

Common to *all* matrix object in the package:

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a [character](#) vector length equal the corresponding Dim element.

**Methods**

There are (relatively simple) group methods (see, e.g., [Arith](#))

**Arith** signature(e1 = "dMatrix", e2 = "dMatrix"): ...

**Arith** signature(e1 = "dMatrix", e2 = "numeric"): ...

**Arith** signature(e1 = "numeric", e2 = "dMatrix"): ...

**Math** signature(x = "dMatrix"): ...

**Math2** signature(x = "dMatrix", digits = "numeric"): this group contains [round\(\)](#) and [signif\(\)](#).

**Compare** signature(e1 = "numeric", e2 = "dMatrix"): ...

**Compare** signature(e1 = "dMatrix", e2 = "numeric"): ...

**Compare** signature(e1 = "dMatrix", e2 = "dMatrix"): ...

**Summary** signature(x = "dMatrix"): The "Summary" group contains the seven functions `max()`, `min()`, `range()`, `prod()`, `sum()`, `any()`, and `all()`.

The following methods are also defined for all double matrices:

**expm** signature(x = "dMatrix"): computes the "*Matrix Exponential*", see `expm`.

The following methods are defined for all logical matrices:

**which** signature(x = "lsparseMatrix") and many other subclasses of "lMatrix": as the **base** function `which(x, arr.ind)` returns the indices of the `TRUE` entries in x; if `arr.ind` is true, as a 2-column matrix of row and column indices. Since **Matrix** version 1.2-9, if `useNames` is true, as by default, with `dimnames`, the same as `base::which`.

## See Also

The nonzero-pattern matrix class `nMatrix`, which can be used to store non-NA logical matrices even more compactly.

The numeric matrix classes `dgeMatrix`, `dgCMatrix`, and `Matrix`.

`drop0(x, tol=1e-10)` is sometimes preferable to (and more efficient than) `zapsmall(x, digits=10)`.

## Examples

```
showClass("dMatrix")

set.seed(101)
round(Matrix(rnorm(28), 4,7), 2)
M <- Matrix(rlnorm(56, sd=10), 4,14)
(M. <- zapsmall(M))
table(as.logical(M. == 0))
```

---

dmperm

Dulmage-Mendelsohn Permutation / Decomposition

---

## Description

For any  $n \times m$  (typically) sparse matrix x compute the Dulmage-Mendelsohn row and columns permutations which at first splits the  $n$  rows and  $m$  columns into coarse partitions each; and then a finer one, reordering rows and columns such that the permuted matrix is "as upper triangular" as possible.

## Usage

```
dmperm(x, nAns = 6L, seed = 0L)
```

## Arguments

|      |                                                                                                                                                                                                                                                                                                                          |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x    | a typically sparse matrix; internally coerced to either " <code>dgCMatrix</code> " or " <code>dtCMatrix</code> ".                                                                                                                                                                                                        |
| nAns | an integer specifying the <code>length</code> of the resulting <code>list</code> . Must be 2, 4, or 6.                                                                                                                                                                                                                   |
| seed | an integer code in -1,0,1; determining the (initial) permutation; by default, <code>seed = 0</code> , no (or the identity) permutation; <code>seed = -1</code> uses the "reverse" permutation <code>k:1</code> ; for <code>seed = 1</code> , it is a <i>random</i> permutation (using R's RNG, <code>seed</code> , etc). |

## Details

See the book section by Tim Davis; page 122–127, in the References.

## Value

a named [list](#) with (by default) 6 components,

|     |                                                                                  |
|-----|----------------------------------------------------------------------------------|
| p   | integer vector with the permutation p, of length nrow(x).                        |
| q   | integer vector with the permutation q, of length ncol(x).                        |
| r   | integer vector of length nb+1, where block k is rows r[k] to r[k+1]-1 in A[p,q]. |
| s   | integer vector of length nb+1, where block k is cols s[k] to s[k+1]-1 in A[p,q]. |
| rr5 | integer vector of length 5, defining the coarse row decomposition.               |
| cc5 | integer vector of length 5, defining the coarse column decomposition.            |

[Schur](#), the class of permutation matrices; “[pMatrix](#)”.

## Examples

```
set.seed(17)
(S9 <- rsparsematrix(9, 9, nnz = 10, symmetric=TRUE)) # dsCMatrix
str(dm9 <- dmperm(S9))
(S9p <- with(dm9, S9[p, q]))
looks good, but *not* quite upper triangular; these, too:
str(dm9.0 <- dmperm(S9, seed=-1)) # non-random too.
str(dm9_1 <- dmperm(S9, seed= 1)) # a random one
The last two permutations differ, but have the same effect!
(S9p0 <- with(dm9.0, S9[p, q])) # .. hmm ..
stopifnot(all.equal(S9p0, S9p))# same as as default, but different from the random one
```

```
set.seed(11)
(M <- triu(rsparsematrix(9,11, 1/4)))
dM <- dmperm(M); with(dM, M[p, q])
(Mp <- M[sample.int(nrow(M)), sample.int(ncol(M))])
dMp <- dmperm(Mp); with(dMp, Mp[p, q])
```

```
set.seed(7)
(n7 <- rsparsematrix(5, 12, nnz = 10, rand.x = NULL))
str(dm.7 <- dmperm(n7))
stopifnot(exprs = {
 lengths(dm.7[1:2]) == dim(n7)
```

```

 identical(dm.7, dmperm(as(n7, "dMatrix")))
 identical(dm.7[1:4], dmperm(n7, nAns=4))
 identical(dm.7[1:2], dmperm(n7, nAns=2))
 })

```

dpoMatrix-class

*Positive Semi-definite Dense (Packed | Non-packed) Numeric Matrices*

## Description

- The "dpoMatrix" class is the class of positive-semidefinite symmetric matrices in nonpacked storage.
- The "dppMatrix" class is the same except in packed storage. Only the upper triangle or the lower triangle is required to be available.
- The "corMatrix" and "copMatrix" classes represent correlation matrices. They extend "dpoMatrix" and "dppMatrix", respectively, with an additional slot sd allowing restoration of the original covariance matrix.

## Objects from the Class

Objects can be created by calls of the form `new("dpoMatrix", ...)` or from `crossprod` applied to an "dgeMatrix" object.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

**Dimnames:** inherited from class "Matrix"

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**sd:** (for "corMatrix" and "copMatrix") a [numeric](#) vector of length n containing the (original)  $\sqrt{\text{var}(\cdot)}$  entries which allow reconstruction of a covariance matrix from the correlation matrix.

## Extends

Class "dsyMatrix", directly.

Classes "dgeMatrix", "symmetricMatrix", and many more by class "dsyMatrix".

## Methods

**chol** signature(x = "dpoMatrix"): Returns (and stores) the Cholesky decomposition of x, see [chol](#).

**determinant** signature(x = "dpoMatrix"): Returns the [determinant](#) of x, via `chol(x)`, see above.

**rcond** signature( $x = \text{"dpoMatrix"}$ ,  $\text{norm} = \text{"character"}$ ): Returns (and stores) the reciprocal of the condition number of  $x$ . The norm can be "O" for the one-norm (the default) or "I" for the infinity-norm. For symmetric matrices the result does not depend on the norm.

**solve** signature( $a = \text{"dpoMatrix"}$ ,  $b = \text{"..."}\text{"}$ ), and

**solve** signature( $a = \text{"dppMatrix"}$ ,  $b = \text{"..."}\text{"}$ ) work via the Cholesky composition, see also the Matrix [solve-methods](#).

**Arith** signature( $e1 = \text{"dpoMatrix"}$ ,  $e2 = \text{"numeric"}$ ) (and quite a few other signatures): The result of ("elementwise" defined) arithmetic operations is typically *not* positive-definite anymore. The only exceptions, currently, are multiplications, divisions or additions with *positive* `length(.) == 1` numbers (or [logicals](#)).

### Note

Currently the validity methods for these classes such as [getValidity](#)(`getClass("dpoMatrix")`) for efficiency reasons only check the diagonal entries of the matrix – they may not be negative. This is only necessary but not sufficient for a symmetric matrix to be positive semi-definite.

A more reliable (but often more expensive) check for positive semi-definiteness would look at the signs of `diag(BunchKaufman(.))` (with some tolerance for very small negative values), and for (strict) positive definiteness at something like `!inherits(tryCatch(chol(.), error=identity), "error")`. Indeed, when *coercing* to these classes, a version of [Cholesky](#)() or [chol](#)() is typically used, e.g., see `selectMethod("coerce", c(from="dsyMatrix", to="dpoMatrix"))`.

### See Also

Classes [dsyMatrix](#) and [dgeMatrix](#); further, [Matrix](#), [rcond](#), [chol](#), [solve](#), [crossprod](#).

### Examples

```
h6 <- Hilbert(6)
rcond(h6)
str(h6)
h6 * 27720 # is ``integer``
solve(h6)
str(hp6 <- pack(h6))

Note that as(*, "corMatrix") *scales* the matrix
(ch6 <- as(h6, "corMatrix"))
stopifnot(all.equal(as(h6 * 27720, "dsyMatrix"), round(27720 * h6),
 tolerance = 1e-14),
 all.equal(ch6@sd^(-2), 2*(1:6)-1,
 tolerance = 1e-12))
chch <- Cholesky(ch6, perm = FALSE)
stopifnot(identical(chch, ch6@factors$Cholesky),
 all(abs(crossprod(as(chch, "dtrMatrix")) - ch6) < 1e-10))
```

---

drop0

*Drop Non-Structural Zeros from a Sparse Matrix*

---

### Description

Deletes “non-structural” zeros (i.e., zeros stored explicitly, in memory) from a sparse matrix and returns the result.

**Usage**

```
drop0(x, tol = 0, is.Csparse = NA, give.Csparse = TRUE)
```

**Arguments**

|              |                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x            | a <a href="#">Matrix</a> , typically inheriting from virtual class <a href="#">sparseMatrix</a> . <a href="#">denseMatrix</a> and traditional vectors and matrices are coerced to <a href="#">CsparseMatrix</a> , with zeros dropped automatically, hence users passing such x should consider <code>as(x, "CsparseMatrix")</code> instead, notably in the <code>tol = 0</code> case. |
| tol          | a non-negative number. If x is numeric, then entries less than or equal to tol in absolute value are deleted.                                                                                                                                                                                                                                                                         |
| is.Csparse   | a logical used only if <code>give.Csparse</code> is TRUE, indicating if x already inherits from virtual class <a href="#">CsparseMatrix</a> , in which case coercion is not attempted, permitting some (typically small) speed-up.                                                                                                                                                    |
| give.Csparse | a logical indicating if the result must inherit from virtual class <a href="#">CsparseMatrix</a> . If FALSE and x inherits from <a href="#">RsparseMatrix</a> , <a href="#">TsparseMatrix</a> , or <a href="#">indMatrix</a> , then the result preserves the class of x. The default value is TRUE only for backwards compatibility.                                                  |

**Value**

A [sparseMatrix](#), the result of deleting non-structural zeros from x, possibly after coercion.

**Note**

`drop0` is sometimes called in conjunction with [zapsmall](#), e.g., when dealing with sparse matrix products; see the example.

**See Also**

Function [sparseMatrix](#), for constructing objects inheriting from virtual class [sparseMatrix](#); [nnzero](#).

**Examples**

```
(m <- sparseMatrix(i = 1:8, j = 2:9, x = c(0:2, 3:-1),
 dims = c(10L, 20L)))
drop0(m)

A larger example:
t5 <- new("dtCMatrix", Dim = c(5L, 5L), uplo = "L",
 x = c(10, 1, 3, 10, 1, 10, 1, 10, 10),
 i = c(0L,2L,4L, 1L, 3L,2L,4L, 3L, 4L),
 p = c(0L, 3L, 5L, 7:9))
TT <- kronecker(t5, kronecker(kronecker(t5, t5), t5))
IT <- solve(TT)
I. <- TT %%% IT ; nnzero(I.) # 697 (== 625 + 72)
I.0 <- drop0(zapsmall(I.))
which actually can be more efficiently achieved by
I.. <- drop0(I., tol = 1e-15)
stopifnot(all(I.0 == Diagonal(625)), nnzero(I..) == 625)
```

## Description

The dsCMatrix class is a class of symmetric, sparse numeric matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The dsTMatrix class is the class of symmetric, sparse numeric matrices in triplet format.

## Objects from the Class

Objects can be created by calls of the form `new("dsCMatrix", ...)` or `new("dsTMatrix", ...)`, or automatically via e.g., `as(*, "symmetricMatrix")`, or (for dsCMatrix) also from `Matrix(.)`.

Creation "from scratch" most efficiently happens via `sparseMatrix(*, symmetric=TRUE)`.

## Slots

**uplo:** A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored.

**i:** Object of class "integer" of length nnZ (*half* number of non-zero elements). These are the row numbers for each non-zero element in the lower triangle of the matrix.

**p:** (only in class "dsCMatrix":) an [integer](#) vector for providing pointers, one for each column, see the detailed description in [CsparseMatrix](#).

**j:** (only in class "dsTMatrix":) Object of class "integer" of length nnZ (as i). These are the column numbers for each non-zero element in the lower triangle of the matrix.

**x:** Object of class "numeric" of length nnZ – the non-zero elements of the matrix (to be duplicated for full matrix).

**factors:** Object of class "list" - a list of factorizations of the matrix.

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

## Extends

Both classes extend classes [symmetricMatrix](#) [dsparseMatrix](#) directly; dsCMatrix further directly extends [CsparseMatrix](#), where dsTMatrix does [TsparseMatrix](#).

## Methods

**solve** signature(a = "dsCMatrix", b = "..."): `x <- solve(a,b)` solves  $Ax = b$  for  $x$ ; see [solve-methods](#).

**chol** signature(x = "dsCMatrix", pivot = "logical"): Returns (and stores) the Cholesky decomposition of x, see [chol](#).

**Cholesky** signature(A = "dsCMatrix",...): Computes more flexibly Cholesky decompositions, see [Cholesky](#).

**determinant** signature(x = "dsCMatrix", logarithm = "missing"): Evaluate the determinant of x on the logarithm scale. This creates and stores the Cholesky factorization.

- determinant** signature(x = "dsCMatrix", logarithm = "logical"): Evaluate the determinant of x on the logarithm scale or not, according to the logarithm argument. This creates and stores the Cholesky factorization.
- t** signature(x = "dsCMatrix"): Transpose. As for all symmetric matrices, a matrix for which the upper triangle is stored produces a matrix for which the lower triangle is stored and vice versa, i.e., the uplo slot is swapped, and the row and column indices are interchanged.
- t** signature(x = "dsTMatrix"): Transpose. The uplo slot is swapped from "U" to "L" or vice versa, as for a "dsCMatrix", see above.

### See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#) and those mentioned above.

### Examples

```
mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)
mm # automatically dsCMatrix
str(mm)
mT <- as(as(mm, "generalMatrix"), "TsparseMatrix")

Either
(symM <- as(mT, "symmetricMatrix")) # dsT
(symC <- as(symM, "CsparseMatrix")) # dsC
or
sT <- Matrix(mT, sparse=TRUE, forceCheck=TRUE) # dsT

sym2 <- as(symC, "TsparseMatrix")
--> the same as 'symM', a "dsTMatrix"
```

---

dsparseMatrix-class      *Virtual Class "dsparseMatrix" of Numeric Sparse Matrices*

---

### Description

The Class "dsparseMatrix" is the virtual (super) class of all numeric sparse matrices.

### Slots

- Dim:** the matrix dimension, see class "[Matrix](#)".
- Dimnames:** see the "[Matrix](#)" class.
- x:** a [numeric](#) vector containing the (non-zero) matrix entries.

### Extends

- Class "dMatrix" and "sparseMatrix", directly.
- Class "Matrix", by the above classes.

### See Also

the documentation of the (non virtual) sub classes, see `showClass("dsparseMatrix")`; in particular, [dgTMatrix](#), [dgCMatrix](#), and [dgRMatrix](#).

**Examples**

```
showClass("dsparseMatrix")
```

---

dsRMatrix-class

*Symmetric Sparse Compressed Row Matrices*

---

**Description**

The `dsRMatrix` class is a class of symmetric, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Objects from the Class**

These `"..RMatrix"` classes are currently still mostly unimplemented!

Objects can be created by calls of the form `new("dsRMatrix", ...)`.

**Slots**

**uplo:** A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored. At present only the lower triangle form is allowed.

**j:** Object of class `"integer"` of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p:** Object of class `"integer"` of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**factors:** Object of class `"list"` - a list of factorizations of the matrix.

**x:** Object of class `"numeric"` - the non-zero elements of the matrix.

**Dim:** Object of class `"integer"` - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** List of length two, see [Matrix](#).

**Extends**

Classes [dsparseMatrix](#), [symmetricMatrix](#), and [RsparseMatrix](#), directly.

Class `"dMatrix"`, by class `"dsparseMatrix"`; class `"sparseMatrix"`, by classes `"dsparseMatrix"` and `"RsparseMatrix"`.

**Methods**

**forceSymmetric** signature(`x = "dsRMatrix"`, `uplo = "missing"`): a trivial method just returning `x`

**forceSymmetric** signature(`x = "dsRMatrix"`, `uplo = "character"`): if `uplo == x@uplo`, this trivially returns `x`; otherwise `t(x)`.

**See Also**

the classes [dgCMatrix](#), [dgTMatrix](#), and [dgeMatrix](#).

**Examples**

```
(m0 <- new("dsRMatrix"))
m2 <- new("dsRMatrix", Dim = c(2L,2L),
 x = c(3,1), j = c(1L,1L), p = 0:2)
m2
stopifnot(colSums(as(m2, "TsparseMatrix")) == 3:4)
str(m2)
(ds2 <- forceSymmetric(diag(2))) # dsy*
dR <- as(ds2, "RsparseMatrix")
dR # dsRMatrix
```

dsyMatrix-class

*Symmetric Dense (Packed or Unpacked) Numeric Matrices***Description**

- The "dsyMatrix" class is the class of symmetric, dense matrices in *non-packed* storage and
- "dspMatrix" is the class of symmetric dense matrices in *packed* storage, see [pack\(\)](#). Only the upper triangle or the lower triangle is stored.

**Objects from the Class**

Objects can be created by calls of the form `new("dsyMatrix", ...)` or `new("dspMatrix", ...)`, respectively.

**Slots**

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#).

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

"dsyMatrix" extends class "dgeMatrix", directly, whereas  
 "dspMatrix" extends class "ddenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, *indirectly*, use [showClass\("dsyMatrix"\)](#), e.g., for details.

**Methods**

**norm** signature(`x = "dspMatrix"`, `type = "character"`), or `x = "dsyMatrix"` or `type = "missing"`: Computes the matrix norm of the desired type, see, [norm](#).

**rcond** signature(`x = "dspMatrix"`, `type = "character"`), or `x = "dsyMatrix"` or `type = "missing"`: Computes the reciprocal condition number, [rcond\(\)](#).

**solve** signature(`a = "dspMatrix"`, `b = "..."`), and

**solve** signature(a = "dsyMatrix", b = "..."):  $x \leftarrow \text{solve}(a, b)$  solves  $Ax = b$  for  $x$ ; see [solve-methods](#).

**t** signature(x = "dsyMatrix"): Transpose; swaps from upper triangular to lower triangular storage, i.e., the uplo slot from "U" to "L" or vice versa, the same as for all symmetric matrices.

### See Also

The *positive (Semi-)definite* dense (packed or non-packed numeric matrix classes [dpoMatrix](#), [dppMatrix](#) and [corMatrix](#),

Classes [dgeMatrix](#) and [Matrix](#); [solve](#), [norm](#), [rcond](#), [t](#)

### Examples

```
Only upper triangular part matters (when uplo == "U" as per default)
(sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77)))
str(t(sy2)) # uplo = "L", and the lower tri. (i.e. NA is replaced).

chol(sy2) #-> "Cholesky" matrix
(sp2 <- pack(sy2)) # a "dspMatrix"

Coercing to dpoMatrix gives invalid object:
sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7))
try(as(sy3, "dpoMatrix")) # -> error: not positive definite

4x4 example
m <- matrix(0,4,4); m[upper.tri(m)] <- 1:6
(sym <- m+t(m)+diag(11:14, 4))
(S1 <- pack(sym))
(S2 <- t(S1))
stopifnot(all(S1 == S2)) # equal "seen as matrix", but differ internally :
str(S1)
S2@x
```

---

dtCMatrix-class

*Triangular, (compressed) sparse column matrices*

---

### Description

The "dtCMatrix" class is a class of triangular, sparse matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The "dtTMatrix" class is a class of triangular, sparse matrices in triplet format.

### Objects from the Class

Objects can be created by calls of the form `new("dtCMatrix", ...)` or calls of the form `new("dtTMatrix", ...)`, but more typically automatically via [Matrix\(\)](#) or coercions such as `as(x, "triangularMatrix")`.

**Slots**

- uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- p: (only present in "dtCMatrix":) an [integer](#) vector for providing pointers, one for each column, see the detailed description in [CsparseMatrix](#).
- i: Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- j: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each non-zero element in the matrix. (Only present in the dtTMatrix class.)
- x: Object of class "numeric" - the non-zero elements of the matrix.
- Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

**Extends**

Class "dgCMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix", "sparseMatrix", and more by class "dgCMatrix" etc, see the examples.

**Methods**

- solve** signature(a = "dtCMatrix", b = "..."): sparse triangular solve (aka "backsolve" or "forwardsolve"), see [solve-methods](#).
- t** signature(x = "dtCMatrix"): returns the transpose of x
- t** signature(x = "dtTMatrix"): returns the transpose of x

**See Also**

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#), and [dtrMatrix](#).

**Examples**

```
showClass("dtCMatrix")
showClass("dtTMatrix")
t1 <- new("dtTMatrix", x= c(3,7), i= 0:1, j=3:2, Dim= as.integer(c(4,4)))
t1
from 0-diagonal to unit-diagonal {low-level step}:
tu <- t1 ; tu@diag <- "U"
tu
(cu <- as(tu, "CsparseMatrix"))
str(cu)# only two entries in @i and @x
stopifnot(cu@i == 1:0,
 all(2 * sympart(cu) == Diagonal(4) + forceSymmetric(cu)))

t1[1,2:3] <- -1:-2
diag(t1) <- 10*c(1:2,3:2)
t1 # still triangular
(it1 <- solve(t1))
t1. <- solve(it1)
all(abs(t1 - t1.) < 10 * .Machine$double.eps)
```

```
2nd example
U5 <- new("dtCMatrix", i= c(1L, 0:3), p=c(0L,0L,0:2, 5L), Dim = c(5L, 5L),
 x = rep(1, 5), diag = "U")
U5
(iu <- solve(U5)) # contains one '0'
validObject(iu2 <- solve(U5, Diagonal(5)))# failed in earlier versions

I5 <- iu %*% U5 # should equal the identity matrix
i5 <- iu2 %*% U5
m53 <- matrix(1:15, 5,3, dimnames=list(NULL,letters[1:3]))
asDiag <- function(M) as(drop0(M), "diagonalMatrix")
stopifnot(
 all.equal(Diagonal(5), asDiag(I5), tolerance=1e-14) ,
 all.equal(Diagonal(5), asDiag(i5), tolerance=1e-14) ,
 identical(list(NULL, dimnames(m53)[[2]]), dimnames(solve(U5, m53)))
)
```

---

dtpMatrix-class

Packed Triangular Dense Matrices - "dtpMatrix"

---

## Description

The "dtpMatrix" class is the class of triangular, dense, numeric matrices in packed storage. The "dtrMatrix" class is the same except in nonpacked storage.

## Objects from the Class

Objects can be created by calls of the form `new("dtpMatrix", ...)` or by coercion from other classes of matrices.

## Slots

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order. For a packed square matrix of dimension  $d \times d$ , `length(x)` is of length  $d(d+1)/2$  (also when `diag == "U"`!).
- Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix" and more by class "ddenseMatrix" etc, see the examples.

## Methods

**%\*%** signature(x = "dtpMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see `showMethods("%*%", class = "dtpMatrix")`.

**determinant** signature(x = "dtpMatrix", logarithm = "logical"): the `determinant(x)` trivially is `prod(diag(x))`, but computed on log scale to prevent over- and underflow.

**diag** signature(x = "dtpMatrix"): ...

**norm** signature(x = "dtpMatrix", type = "character"): ...

**rcond** signature(x = "dtpMatrix", norm = "character"): ...

**solve** signature(a = "dtpMatrix", b = "..."): efficiently using internal backsolve or forward-solve, see [solve-methods](#).

**t** signature(x = "dtpMatrix"): `t(x)` remains a "dtpMatrix", lower triangular if x is upper triangular, and vice versa.

## See Also

Class [dtrMatrix](#)

## Examples

```
showClass("dtrMatrix")

example("dtrMatrix-class", echo=FALSE)
(p1 <- pack(T2))
str(p1)
(pp <- pack(T))
ip1 <- solve(p1)
stopifnot(length(p1@x) == 3, length(pp@x) == 3,
 p1 @ uplo == T2 @ uplo, pp @ uplo == T @ uplo,
 identical(t(pp), p1), identical(t(p1), pp),
 all((l.d <- p1 - T2) == 0), is(l.d, "dtpMatrix"),
 all((u.d <- pp - T) == 0), is(u.d, "dtpMatrix"),
 l.d@uplo == T2@uplo, u.d@uplo == T@uplo,
 identical(t(ip1), solve(pp)), is(ip1, "dtpMatrix"),
 all.equal(as(solve(p1,p1), "diagonalMatrix"), Diagonal(2)))
```

---

dtRMatrix-class

*Triangular Sparse Compressed Row Matrices*

---

## Description

The `dtRMatrix` class is a class of triangular, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing columnnd order.

## Objects from the Class

This class is currently still mostly unimplemented!

Objects can be created by calls of the form `new("dtRMatrix", ...)`.

**Slots**

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. At present only the lower triangle form is allowed.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**j:** Object of class "integer" of length `nnzero(.)` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p:** Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row. (Only present in the dsRMatrix class.)

**x:** Object of class "numeric" - the non-zero elements of the matrix.

**Dim:** The dimension (a length-2 "integer")

**Dimnames:** corresponding names (or NULL), inherited from the [Matrix](#), see there.

**Extends**

Class "dgRMatrix", directly. Class "dsparseMatrix", by class "dgRMatrix". Class "dMatrix", by class "dgRMatrix". Class "sparseMatrix", by class "dgRMatrix". Class "Matrix", by class "dgRMatrix".

**Methods**

No methods currently with class "dsRMatrix" in the signature.

**See Also**

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#)

**Examples**

```
(m0 <- new("dtrMatrix"))
(m2 <- new("dtrMatrix", Dim = c(2L,2L),
 x = c(5, 1:2), p = c(0L,2:3), j = c(0:1,1L)))
str(m2)
(m3 <- as(Diagonal(2), "RsparseMatrix"))# --> dtrMatrix
```

---

dtrMatrix-class

*Triangular, dense, numeric matrices*

---

**Description**

The "dtrMatrix" class is the class of triangular, dense, numeric matrices in nonpacked storage. The "dtpMatrix" class is the same except in packed storage, see [pack\(\)](#).

**Objects from the Class**

Objects can be created by calls of the form `new("dtrMatrix", ...)`.

**Slots**

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

**Extends**

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "Matrix" and others, by class "ddenseMatrix".

**Methods**

Among others (such as matrix products, e.g. [?crossprod-methods](#)),

**norm** signature(x = "dtrMatrix", type = "character"): ..

**rcond** signature(x = "dtrMatrix", norm = "character"): ..

**solve** signature(a = "dtrMatrix", b = "..."): efficiently use a "forwardsolve" or backsolve for a lower or upper triangular matrix, respectively, see also [solve-methods](#).

**+, -, \*, ..., ==, >=, ...** all the [Ops](#) group methods are available. When applied to two triangular matrices, these return a triangular matrix when easily possible.

**See Also**

Classes [ddenseMatrix](#), [dtpMatrix](#), [triangularMatrix](#)

**Examples**

```
(m <- rbind(2:3, 0:-1))
(M <- as(m, "generalMatrix"))

(T <- as(M, "triangularMatrix")) # formally upper triangular
(T2 <- as(t(M), "triangularMatrix"))
stopifnot(T@uplo == "U", T2@uplo == "L", identical(T2, t(T)))

m <- matrix(0,4,4); m[upper.tri(m)] <- 1:6
(t1 <- Matrix(m+diag(,4)))
str(t1p <- pack(t1))
(t1pu <- diagN2U(t1p))
stopifnot(exprs = {
 inherits(t1, "dtrMatrix"); validObject(t1)
 inherits(t1p, "dtpMatrix"); validObject(t1p)
 inherits(t1pu, "dtCMatrix"); validObject(t1pu)
 t1pu@x == 1:6
 all(t1pu == t1p)
 identical((t1pu - t1)@x, numeric())# sparse all-0
})
```

---

|                |                                     |
|----------------|-------------------------------------|
| expand-methods | <i>Expand Matrix Factorizations</i> |
|----------------|-------------------------------------|

---

**Description**

expand1 and expand2 construct matrix factors from objects specifying matrix factorizations. Such objects typically do not store the factors explicitly, employing instead a compact representation to save memory.

**Usage**

```
expand1(x, which, ...)
expand2(x, ...)

expand (x, ...)
```

**Arguments**

|       |                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------|
| x     | a matrix factorization, typically inheriting from virtual class <a href="#">MatrixFactorization</a> . |
| which | a character string indicating a matrix factor.                                                        |
| ...   | further arguments passed to or from methods.                                                          |

**Details**

Methods for expand are retained only for backwards compatibility with **Matrix** < 1.6-0. New code should use expand1 and expand2, whose methods provide more control and behave more consistently. Notably, expand2 obeys the rule that the product of the matrix factors in the returned list should reproduce (within some tolerance) the factorized matrix, *including* its dimnames.

Hence if x is a matrix and y is its factorization, then

```
all.equal(as(x, "matrix"), as(Reduce(`%*%`, expand2(y)), "matrix"))
```

should in most cases return TRUE.

**Value**

expand1 returns an object inheriting from virtual class [Matrix](#), representing the factor indicated by which, always without row and column names.

expand2 returns a list of factors, typically with names using conventional notation, as in list(L=, U=). The first and last factors get the row and column names of the factorized matrix, which are preserved in the Dimnames slot of x.

**Methods**

The following table lists methods for expand1 together with allowed values of argument which.

|                         |                          |
|-------------------------|--------------------------|
| class(x)                | which                    |
| <a href="#">Schur</a>   | c("Q", "T", "Q.")        |
| <a href="#">denseLU</a> | c("P1", "P1.", "L", "U") |

```

sparseLU c("P1", "P1.", "P2", "P2.", "L", "U")
sparseQR c("P1", "P1.", "P2", "P2.", "Q", "Q1", "R", "R1")
BunchKaufman, pBunchKaufman c("U", "DU", "U.", "L", "DL", "L.")
Cholesky, pCholesky c("P1", "P1.", "L1", "D", "L1.", "L", "L.")
CHMsiml, CHMsiml c("P1", "P1.", "L1", "D", "L1.", "L", "L.")

```

Methods for `expand2` and `expand` are described below. Factor names and classes apply also to `expand1`.

`expand2 signature(x = "CHMsiml")`: expands the factorization  $A = P_1' L_1 D L_1' P_1 = P_1' L L' P_1$  as `list(P1., L1, D, L1., P1)` (the default) or as `list(P1., L, L., P1)`, depending on optional logical argument `LDL`. `P1` and `P1.` are `pMatrix`, `L1`, `L1.`, `L`, and `L.` are `dtcMatrix`, and `D` is a `ddiMatrix`.

`expand2 signature(x = "CHMsuper")`: as `CHMsiml`, but the triangular factors are stored as `dgCMatrix`.

`expand2 signature(x = "p?Cholesky")`: expands the factorization  $A = L_1 D L_1' = L L'$  as `list(L1, D, L1.)` (the default) or as `list(L, L.)`, depending on optional logical argument `LDL`. `L1`, `L1.`, `L`, and `L.` are `dtrMatrix` or `dtpMatrix`, and `D` is a `ddiMatrix`.

`expand2 signature(x = "p?BunchKaufman")`: expands the factorization  $A = U D_U U' = L D_L L'$  where  $U = \prod_{k=1}^{b_U} P_k U_k$  and  $L = \prod_{k=1}^{b_L} P_k L_k$  as `list(U, DU, U.)` or `list(L, DL, L.)`, depending on `x@uplo`. If optional argument `complete` is `TRUE`, then an unnamed list giving the full expansion with  $2b_U + 1$  or  $2b_L + 1$  matrix factors is returned instead.  $P_k$  are represented as `pMatrix`,  $U_k$  and  $L_k$  are represented as `dtcMatrix`, and  $D_U$  and  $D_L$  are represented as `dsCMatrix`.

`expand2 signature(x = "Schur")`: expands the factorization  $A = Q T Q'$  as `list(Q, T, Q.)`. `Q` and `Q.` are `x@Q` and `t(x@Q)` modulo `Dimnames`, and `T` is `x@T`.

`expand2 signature(x = "sparseLU")`: expands the factorization  $A = P_1' L U P_2'$  as `list(P1., L, U, P2.)`. `P1.` and `P2.` are `pMatrix`, and `L` and `U` are `dtCMatrix`.

`expand2 signature(x = "denseLU")`: expands the factorization  $A = P_1' L U$  as `list(P1., L, U)`. `P1.` is a `pMatrix`, and `L` and `U` are `dtrMatrix` if square and `dgeMatrix` otherwise.

`expand2 signature(x = "sparseQR")`: expands the factorization  $A = P_1' Q R P_2' = P_1' Q_1 R_1 P_2'$  as `list(P1., Q, R, P2.)` or `list(P1., Q1, R1, P2.)`, depending on optional logical argument `complete`. `P1.` and `P2.` are `pMatrix`, `Q` and `Q1` are `dgeMatrix`, `R` is a `dgCMatrix`, and `R1` is a `dtCMatrix`.

`expand signature(x = "CHMfactor")`: as `expand2`, but returning `list(P, L)`. `expand(x)[["P"]]` and `expand2(x)[["P1"]]` represent the same permutation matrix  $P_1$  but have opposite margin slots and inverted perm slots. The components of `expand(x)` do not preserve `x@Dimnames`.

`expand signature(x = "sparseLU")`: as `expand2`, but returning `list(P, L, U, Q)`. `expand(x)[["Q"]]` and `expand2(x)[["P2.")]` represent the same permutation matrix  $P_2'$  but have opposite margin slots and inverted perm slots. `expand(x)[["P"]]` represents the permutation matrix  $P_1$  rather than its transpose  $P_1'$ ; it is `expand2(x)[["P1.")]` with an inverted perm slot. `expand(x)[["L"]]` and `expand2(x)[["L"]]` represent the same unit lower triangular matrix  $L$ , but with diag slot equal to `"N"` and `"U"`, respectively. `expand(x)[["L"]]` and `expand(x)[["U"]]` store the *permuted* first and second components of `x@Dimnames` in their `Dimnames` slots.

`expand signature(x = "denseLU")`: as `expand2`, but returning `list(L, U, P)`. `expand(x)[["P"]]` and `expand2(x)[["P1.")]` are identical modulo `Dimnames`. The components of `expand(x)` do not preserve `x@Dimnames`.

**See Also**

The virtual class [MatrixFactorization](#) of matrix factorizations.

Generic functions [Cholesky](#), [BunchKaufman](#), [Schur](#), [lu](#), and [qr](#) for *computing* factorizations.

**Examples**

```
showMethods("expand1", inherited = FALSE)
showMethods("expand2", inherited = FALSE)
set.seed(0)

(A <- Matrix(rnorm(9L, 0, 10), 3L, 3L))
(lu.A <- lu(A))
(e.lu.A <- expand2(lu.A))
stopifnot(exprs = {
 is.list(e.lu.A)
 identical(names(e.lu.A), c("P1.", "L", "U"))
 all(sapply(e.lu.A, is, "Matrix"))
 all.equal(as(A, "matrix"), as(Reduce(`%*%`, e.lu.A), "matrix"))
})

'expand1' and 'expand2' give equivalent results modulo
dimnames and representation of permutation matrices;
see also function 'alt' in example("Cholesky-methods")
(a1 <- sapply(names(e.lu.A), expand1, x = lu.A, simplify = FALSE))
all.equal(a1, e.lu.A)

see help("denseLU-class") and others for more examples
```

expm-methods

*Matrix Exponential***Description**

Compute the exponential of a matrix.

**Usage**

```
expm(x)
```

**Arguments**

**x** a matrix, typically inheriting from the [dMatrix](#) class.

**Details**

The exponential of a matrix is defined as the infinite Taylor series  $\text{expm}(A) = I + A + A^2/2! + A^3/3! + \dots$  (although this is definitely not the way to compute it). The method for the `dgeMatrix` class uses Ward's diagonal Pade' approximation with three step preconditioning, a recommendation from Moler & Van Loan (1978) "Nineteen dubious ways...".

**Value**

The matrix exponential of `x`.

**Author(s)**

This is a translation of the implementation of the corresponding Octave function contributed to the Octave project by A. Scottedward Hodel <A.S.Hodel@Eng.Auburn.EDU>. A bug in there has been fixed by Martin Maechler.

**See Also**

Package **expm**, which provides newer (in some cases faster, more accurate) algorithms for computing the matrix exponential via its own (non-generic) function `expm()`. **expm** also implements `logm()`, `sqrtm()`, etc.

Generic function [Schur](#).

**Examples**

```
(m1 <- Matrix(c(1,0,1,1), ncol = 2))
(e1 <- expm(m1)) ; e <- exp(1)
stopifnot(all.equal(e1@x, c(e,0,e,e), tolerance = 1e-15))
(m2 <- Matrix(c(-49, -64, 24, 31), ncol = 2))
(e2 <- expm(m2))
(m3 <- Matrix(cbind(0, rbind(6*diag(3), 0)))) # sparse!
(e3 <- expm(m3)) # upper triangular
```

---

externalFormats

Read and write external matrix formats

---

**Description**

Read matrices stored in the Harwell-Boeing or MatrixMarket formats or write `sparseMatrix` objects to one of these formats.

**Usage**

```
readHB(file)
readMM(file)
writeMM(obj, file, ...)
```

## Arguments

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>obj</code>  | a real sparse matrix                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>file</code> | for <code>writeMM</code> - the name of the file to be written. For <code>readHB</code> and <code>readMM</code> the name of the file to read, as a character scalar. The names of files storing matrices in the Harwell-Boeing format usually end in <code>".rua"</code> or <code>".rsa"</code> . Those storing matrices in the MatrixMarket format usually end in <code>".mtx"</code> .<br>Alternatively, <code>readHB</code> and <code>readMM</code> accept connection objects. |
| <code>...</code>  | optional additional arguments. Currently none are used in any methods.                                                                                                                                                                                                                                                                                                                                                                                                           |

## Value

The `readHB` and `readMM` functions return an object that inherits from the `"Matrix"` class. Methods for the `writeMM` generic functions usually return `NULL` and, as a side effect, the matrix `obj` is written to file in the MatrixMarket format (`writeMM`).

## Note

The Harwell-Boeing format is older and less flexible than the MatrixMarket format. The function `writeHB` was deprecated and has now been removed. Please use `writeMM` instead.

Note that these formats do *not* know anything about `dimnames`, hence these are dropped by `writeMM()`.

A very simple way to export small sparse matrices `S`, is to use `summary(S)` which returns a `data.frame` with columns `i`, `j`, and possibly `x`, see `summary` in `sparseMatrix-class`, and an example below.

## References

<https://math.nist.gov/MatrixMarket/>  
<https://sparse.tamu.edu/>

## Examples

```
str(pores <- readMM(system.file("external/pores_1.mtx", package = "Matrix")))
str(utm <- readHB(system.file("external/utm300.rua", package = "Matrix")))
str(lunda <- readMM(system.file("external/lunda.mtx", package = "Matrix")))
str(lunda <- readHB(system.file("external/lunda.rsa", package = "Matrix")))
https://math.nist.gov/MatrixMarket/data/Harwell-Boeing/counterx/counterx.htm
str(jgl <- readMM(system.file("external/jgl009.mtx", package = "Matrix")))

NOTE: The following examples take quite some time
---- even on a fast internet connection:
if(FALSE) {
 ## The URL has been corrected, but we need an untar step:
 u. <- url("https://www.cise.ufl.edu/research/sparse/RB/Boeing/msc00726.tar.gz")
 str(sm <- readHB(gzcon(u.)))
}

data(KNex, package = "Matrix")
Store as MatrixMarket (".mtx") file, here inside temporary dir./folder:
(MMfile <- file.path(tempdir(), "mmMM.mtx"))
writeMM(KNex$mm, file=MMfile)
file.info(MMfile)[c("size", "ctime")] # (some confirmation of the file's)
```

```
very simple export - in triplet format - to text file:
data(CAex, package = "Matrix")
s.CA <- summary(CAex)
s.CA # shows (i, j, x) [columns of a data frame]
message("writing to ", outf <- tempfile())
write.table(s.CA, file = outf, row.names=FALSE)
and read it back -- showing off sparseMatrix():
str(dd <- read.table(outf, header=TRUE))
has columns (i, j, x) -> we can use via do.call() as arguments to sparseMatrix():
mm <- do.call(sparseMatrix, dd)
stopifnot(all.equal(mm, CAex, tolerance=1e-15))
```

---

facmul-methods

---

*Multiplication by Factors from Matrix Factorizations*

---

## Description

Multiplies a matrix or vector on the left or right by a factor from a matrix factorization or its transpose.

## Usage

```
facmul(x, factor, y, trans = FALSE, left = TRUE, ...)
```

## Arguments

|                     |                                                                                                                                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | a <a href="#">MatrixFactorization</a> object.                                                                                                             |
| <code>factor</code> | a character string indicating a factor in the factorization represented by <code>x</code> , typically an element of <code>names(expand2(x, ...))</code> . |
| <code>y</code>      | a matrix or vector to be multiplied on the left or right by the factor or its transpose.                                                                  |
| <code>trans</code>  | a logical indicating if the transpose of the factor should be used, rather than the factor itself.                                                        |
| <code>left</code>   | a logical indicating if the <code>y</code> should be multiplied on the left by the factor, rather than on the right.                                      |
| <code>...</code>    | further arguments passed to or from methods.                                                                                                              |

## Details

`facmul` is experimental and currently no methods are exported from **Matrix**.

## Value

The value of `op(M) %*% y` or `y %*% op(M)`, depending on `left`, where `M` is the factor (always *without* `dimnames`) and `op(M)` is `M` or `t(M)`, depending on `trans`.

## Examples

```
Conceptually, methods for 'facmul' _would_ behave as follows ...
Not run:
n <- 3L
x <- lu(Matrix(rnorm(n * n), n, n))
y <- rnorm(n)
L <- unname(expand2(x)[[nm <- "L"]])
stopifnot(exprs = {
 all.equal(facmul(x, nm, y, trans = FALSE, left = TRUE), L %*% y)
 all.equal(facmul(x, nm, y, trans = FALSE, left = FALSE), y %*% L)
 all.equal(facmul(x, nm, y, trans = TRUE, left = TRUE), crossprod(L, y))
 all.equal(facmul(x, nm, y, trans = TRUE, left = FALSE), tcrossprod(y, L))
})

End(Not run)
```

---

fastMisc

*“Low Level” Coercions and Methods*

---

## Description

“Semi-API” functions used internally by **Matrix**, often to bypass S4 dispatch and avoid the associated overhead. These are exported to provide this capability to expert users. Typical users should continue to rely on S4 generic functions to dispatch suitable methods, by calling, e.g., `as(. , <class>)` for coercions.

## Usage

```
.M2kind(from, kind = ".", sparse = NA)

.M2gen(from, kind = ".")
.M2sym(from, ...)
.M2tri(from, ...)
.M2diag(from)

.M2v(from)
.M2m(from)
.M2unpacked(from)
.M2packed(from)
.M2C(from)
.M2R(from)
.M2T(from)

.M2V(from)
.m2V(from, kind = ".")

.sparse2dense(from, packed = FALSE)
.diag2dense(from, kind = ".", shape = "t", packed = FALSE, uplo = "U")
.ind2dense(from, kind = "n")
.m2dense(from, class = ".ge", uplo = "U", diag = "N", trans = FALSE)

.dense2sparse(from, repr = "C")
```

```

.diag2sparse(from, kind = ".", shape = "t", repr = "C", uplo = "U")
.ind2sparse(from, kind = "n", repr = ".")
.m2sparse(from, class = ".gC", uplo = "U", diag = "N", trans = FALSE)

.tCRT(x, lazy = TRUE)

.diag.dsC(x, Chx = Cholesky(x, LDL = TRUE), res.kind = "diag")

.solve.dgC.lu (a, b, tol = .Machine$double.eps, check = TRUE)
.solve.dgC.qr (a, b, order = 3L, check = TRUE)
.solve.dgC.chol(a, b, check = TRUE)

.updateCHMfactor(object, parent, mult = 0)

```

## Arguments

|               |                                                                                                                                                                                                                                                                                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| from, x, a, b | a <a href="#">Matrix</a> , matrix, or vector.                                                                                                                                                                                                                                                                                                   |
| kind          | a string (".", "n", "l", or "d") specifying the “kind” of the result. "." indicates that the kind of from should be preserved. "n" is equivalent to "z" if from is complex and to "d" otherwise. "n" indicates that the result should inherit from <a href="#">nMatrix</a> or <a href="#">nsparseVector</a> (and so on).                        |
| shape         | a string (".", "g", "s", or "t") specifying the “shape” of the result. "." indicates that the shape of from should be preserved. "g" indicates that the result should inherit from <a href="#">generalMatrix</a> (and so on).                                                                                                                   |
| repr          | a string (".", "C", "R", or "T") specifying the sparse representation of the result. "." is accepted only by <code>.ind2sparse</code> and indicates the most efficient representation, which is "C" ("R") for <code>margin = 2</code> (1). "C" indicates that the result should inherit from <a href="#">CsparseMatrix</a> (and so on).         |
| packed        | a logical indicating if the result should inherit from <a href="#">packedMatrix</a> rather than from <a href="#">unpackedMatrix</a> . It is ignored for from inheriting from <a href="#">generalMatrix</a> .                                                                                                                                    |
| sparse        | a logical indicating if the result should inherit from <a href="#">sparseMatrix</a> rather than from <a href="#">denseMatrix</a> . If NA, then the result will be formally sparse if and only if from is.                                                                                                                                       |
| uplo          | a string ("U" or "L") indicating whether the result (if symmetric or triangular) should store the upper or lower triangle of from. The elements of from in the opposite triangle are ignored.                                                                                                                                                   |
| diag          | a string ("N" or "U") indicating whether the result (if triangular) should be formally nonunit or unit triangular. In the unit triangular case, the diagonal elements of from are ignored.                                                                                                                                                      |
| trans         | a logical indicating if the result should be a 1-row matrix rather than a 1-column matrix where from is a vector but not a matrix.                                                                                                                                                                                                              |
| class         | a string whose first three characters specify the class of the result. It should match the pattern <code>"^[.nld](ge sy tr sp tp)"</code> for <code>.m2dense</code> and <code>"^[.nld][gst][CRT]"</code> for <code>.m2sparse</code> , where "." in the first position is equivalent to "l" for logical arguments and "d" for numeric arguments. |
| ...           | optional arguments passed to <a href="#">isSymmetric</a> or <a href="#">isTriangular</a> .                                                                                                                                                                                                                                                      |
| lazy          | a logical indicating if the transpose should be constructed with minimal allocation, but possibly <i>without</i> preserving representation.                                                                                                                                                                                                     |
| Chx           | optionally, the <a href="#">Cholesky</a> (x, ...) factorization of x. If supplied, then x is unused.                                                                                                                                                                                                                                            |

|          |                                                                                                                                                                                                                                     |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| res.kind | a string in c("trace", "sumLog", "prod", "min", "max", "range", "diag", "diagBack").                                                                                                                                                |
| tol      | see <a href="#">lu-methods</a> .                                                                                                                                                                                                    |
| order    | see <a href="#">qr-methods</a> .                                                                                                                                                                                                    |
| check    | a logical indicating if the first argument should be tested for inheritance from <a href="#">dgCMatrix</a> and coerced if necessary. Set to FALSE for speed only if it is known to already inherit from <a href="#">dgCMatrix</a> . |
| object   | a Cholesky factorization inheriting from virtual class CHMfactor, almost always the result of a call to generic function <a href="#">Cholesky</a> .                                                                                 |
| parent   | an object of class <a href="#">dsCMatrix</a> or class <a href="#">dgCMatrix</a> .                                                                                                                                                   |
| mult     | a numeric vector of positive length. Only the first element is used, and that must be finite.                                                                                                                                       |

## Details

Functions with names of the form `.<A>2<B>` implement coercions from virtual class A to the “nearest” non-virtual subclass of virtual class B, where the virtual classes are abbreviated as follows:

M [Matrix](#)

V [sparseVector](#)

m matrix

v vector

dense [denseMatrix](#)

unpacked [unpackedMatrix](#)

packed [packedMatrix](#)

sparse [CsparseMatrix](#), [RsparseMatrix](#), or [TsparseMatrix](#)

C [CsparseMatrix](#)

R [RsparseMatrix](#)

T [TsparseMatrix](#)

gen [generalMatrix](#)

sym [symmetricMatrix](#)

tri [triangularMatrix](#)

diag [diagonalMatrix](#)

ind [indMatrix](#)

Abbreviations should be seen as a guide, rather than as an exact description of behaviour. Notably, `.m2dense`, `.m2sparse`, and `.m2V` accept vectors that are not matrices.

`.tCRT(x)`: If `lazy = TRUE`, then `.tCRT` constructs the transpose of `x` using the most efficient representation, which for ‘CRT’ is ‘RCT’. If `lazy = FALSE`, then `.tCRT` preserves the representation of `x`, behaving as the corresponding methods for generic function `t`.

`.diag.dsC(x)`: `.diag.dsC` computes (or uses if `Chx` is supplied) the Cholesky factorization of `x` as  $LDL'$  in order to calculate one of several possible statistics from the diagonal entries of  $D$ . See `res.kind` under ‘Arguments’.

`.solve.dgC.*(a, b)`: `.solve.dgC.lu(a, b)` needs a square matrix `a`. `.solve.dgC.qr(a, b)` needs a “long” matrix `a`, with `nrow(a) >= ncol(a)`. `.solve.dgC.chol(a, b)` needs a “wide” matrix `a`, with `nrow(a) <= ncol(a)`.

All three may be used to solve sparse linear systems directly. Only `.solve.dgC.qr` and `.solve.dgC.chol` be used to solve sparse *least squares* problems.

`.updateCHMfactor(object, parent, mult)`: `.updateCHMfactor` updates `object` with the result of Cholesky factorizing  $F(\text{parent}) + \text{mult}[1] * \text{diag}(\text{nrow}(\text{parent}))$ , i.e.,  $F(\text{parent})$  plus `mult[1]` times the identity matrix, where  $F = \text{identity}$  if `parent` is a `dsCMatrix` and  $F = \text{tcrossprod}$  if `parent` is a `dgCMatrix`. The nonzero pattern of  $F(\text{parent})$  must match that of `S` if `object = Cholesky(S, ...)`.

## Examples

```
D. <- diag(x = c(1, 1, 2, 3, 5, 8))
D.0 <- Diagonal(x = c(0, 0, 0, 3, 5, 8))
S. <- toeplitz(as.double(1:6))
C. <- new("dgCMatrix", Dim = c(3L, 4L),
 p = c(0L, 1L, 1L, 1L, 3L), i = c(1L, 0L, 2L), x = c(-8, 2, 3))
```

```
stopifnot(exprs = {
 identical(.M2tri(D.), as(D., "triangularMatrix"))
 identical(.M2sym(D.), as(D., "symmetricMatrix"))
 identical(.M2diag(D.), as(D., "diagonalMatrix"))
 identical(.M2kind(C., "l"),
 as(C., "lMatrix"))
 identical(.M2kind(.sparse2dense(C.), "l"),
 as(as(C., "denseMatrix"), "lMatrix"))
 identical(.diag2sparse(D.0, ".", "t", "C"),
 .dense2sparse(.diag2dense(D.0, ".", "t", TRUE), "C"))
 identical(.M2gen(.diag2dense(D.0, ".", "s", FALSE)),
 .sparse2dense(.M2gen(.diag2sparse(D.0, ".", "s", "T"))))
 identical(S.,
 .M2m(.m2sparse(S., ".sR")))
 identical(S. * lower.tri(S.) + diag(1, 6L),
 .M2m(.m2dense(S., ".tr", "L", "U")))
 identical(.M2R(C.), .M2R(.M2T(C.)))
 identical(.tCRT(C.), .M2R(t(C.)))
})
```

```
A <- tcrossprod(C.)/6 + Diagonal(3, 1/3); A[1,2] <- 3; A
stopifnot(exprs = {
 is.numeric(x. <- c(2.2, 0, -1.2))
 all.equal(x., .solve.dgC.lu(A, c(1,0,0), check=FALSE))
 all.equal(x., .solve.dgC.qr(A, c(1,0,0), check=FALSE))
})
```

## Solving sparse least squares:

```
X <- rbind(A, Diagonal(3)) # design matrix X (for L.S.)
Xt <- t(X) # *transposed* X (for L.S.)
(y <- drop(crossprod(Xt, 1:3)) + c(-1,1)/1000) # small rand.err.
str(solveCh <- .solve.dgC.chol(Xt, y, check=FALSE)) # Xt *is* dgC..
stopifnot(exprs = {
 all.equal(solveCh$coef, 1:3, tol = 1e-3) # rel.err ~ 1e-4
 all.equal(solveCh$coef, drop(solve(tcrossprod(Xt), Xt %*% y)))
})
```

```

 all.equal(solveCh$coef, .solve.dgC.qr(X, y, check=FALSE))
 })

```

---

## forceSymmetric-methods

*Force a Matrix to 'symmetricMatrix' Without Symmetry Checks*

---

### Description

Force a square matrix `x` to a [symmetricMatrix](#), **without** a symmetry check as it would be applied for `as(x, "symmetricMatrix")`.

### Usage

```
forceSymmetric(x, uplo)
```

### Arguments

|                   |                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | any square matrix (of numbers), either “traditional” ( <a href="#">matrix</a> ) or inheriting from <a href="#">Matrix</a> .                                                                                                                                                                                                          |
| <code>uplo</code> | optional string, “U” or “L” indicating which “triangle” half of <code>x</code> should determine the result. The default is “U” unless <code>x</code> already has a <code>uplo</code> slot (i.e., when it is <a href="#">symmetricMatrix</a> , or <a href="#">triangularMatrix</a> ), where the default will be <code>x@uplo</code> . |

### Value

a square matrix inheriting from class [symmetricMatrix](#).

### See Also

[symmpart](#) for the symmetric part of a matrix, or the coercions `as(x, <symmetricMatrix class>)`.

### Examples

```

Hilbert matrix
i <- 1:6
h6 <- 1/outer(i - 1L, i, "+")
sd <- sqrt(diag(h6))
hh <- t(h6/sd)/sd # theoretically symmetric
isSymmetric(hh, tol=0) # FALSE; hence
try(as(hh, "symmetricMatrix")) # fails, but this works fine:
H6 <- forceSymmetric(hh)

result can be pretty surprising:
(M <- Matrix(1:36, 6))
forceSymmetric(M) # symmetric, hence very different in lower triangle
(tm <- tril(M))
forceSymmetric(tm)

```

## Description

Utilities for formatting sparse numeric matrices in a flexible way. These functions are used by the [format](#) and print methods for sparse matrices and can be applied as well to standard R matrices. Note that *all* arguments but the first are optional.

`formatSparseM()` is the main “workhorse” of [formatSpMatrix](#), the format method for sparse matrices.

`.formatSparseSimple()` is a simple helper function, also dealing with (short/empty) column names construction.

## Usage

```
formatSparseM(x, zero.print = ".", align = c("fancy", "right"),
 m = as(x, "matrix"), asLogical=NULL, uniDiag=NULL,
 digits=NULL, cx, iN0, dn = dimnames(m))

.formatSparseSimple(m, asLogical=FALSE, digits=NULL,
 col.names, note.dropping.colnames = TRUE,
 dn=dimnames(m))
```

## Arguments

- |                                                |                                                                                                                                                                                                             |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                                 | an R object inheriting from class <a href="#">sparseMatrix</a> .                                                                                                                                            |
| <code>zero.print</code>                        | character which should be used for <i>structural</i> zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like <code>print()</code> ing of non-sparse matrices. |
| <code>align</code>                             | a string specifying how the <code>zero.print</code> codes should be aligned, see <a href="#">formatSpMatrix</a> .                                                                                           |
| <code>m</code>                                 | (optional) a (standard R) <a href="#">matrix</a> version of <code>x</code> .                                                                                                                                |
| <code>asLogical</code>                         | should the matrix be formatted as a logical matrix (or rather as a numeric one); mostly for <code>formatSparseM()</code> .                                                                                  |
| <code>uniDiag</code>                           | logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "I" instead of "1" (to emphasize that the 1's are “structural”).                      |
| <code>digits</code>                            | significant digits to use for printing, see <a href="#">print.default</a> .                                                                                                                                 |
| <code>cx</code>                                | (optional) character matrix; a formatted version of <code>x</code> , still with strings such as " <code>0.00</code> " for the zeros.                                                                        |
| <code>iN0</code>                               | (optional) integer vector, specifying the location of the <i>non-zeroes</i> of <code>x</code> .                                                                                                             |
| <code>col.names, note.dropping.colnames</code> | see <a href="#">formatSpMatrix</a> .                                                                                                                                                                        |
| <code>dn</code>                                | <a href="#">dimnames</a> to be used; a list (of length two) with row and column names (or <code>NULL</code> ).                                                                                              |

**Value**

a character matrix like `cx`, where the zeros have been replaced with (padded versions of) `zero.print`. As this is a *dense* matrix, do not use these functions for really large (really) sparse matrices!

**Author(s)**

Martin Maechler

**See Also**

`formatSpMatrix` which calls `formatSparseM()` and is the `format` method for sparse matrices.  
`printSpMatrix` which is used by the (typically implicitly called) `show` and `print` methods for sparse matrices.

**Examples**

```
m <- suppressWarnings(matrix(c(0, 3.2, 0,0, 11,0,0,0,0,-7,0), 4,9))
fm <- formatSparseM(m)
noquote(fm)
nice, but this is nicer {with "units" vertically aligned}:
print(fm, quote=FALSE, right=TRUE)
and "the same" as :
Matrix(m)

align = "right" is cheaper --> the "." are not aligned:
noquote(f2 <- formatSparseM(m,align="r"))
stopifnot(f2 == fm | m == 0, dim(f2) == dim(m),
 (f2 == ".") == (m == 0))
```

---

generalMatrix-class      *Class "generalMatrix" of General Matrices*

---

**Description**

Virtual class of “general” matrices; i.e., matrices that do not have a known property such as symmetric, triangular, or diagonal.

**Objects from the Class**

A virtual Class: No objects may be created from it.

**Slots**

`Dim`, `Dimnames` inherited from virtual class `Matrix`.

`factors` a list of `MatrixFactorization` objects caching factorizations of the matrix. Typically, it is initialized as an empty list and updated “automagically” whenever a factorization is computed.

**Extends**

Class “`Matrix`”, directly.

**See Also**

Virtual classes [symmetricMatrix](#), [triangularMatrix](#), and [diagonalMatrix](#).

---

|         |                                  |
|---------|----------------------------------|
| Hilbert | <i>Generate a Hilbert matrix</i> |
|---------|----------------------------------|

---

**Description**

Generate the  $n$  by  $n$  symmetric Hilbert matrix. Because these matrices are ill-conditioned for moderate to large  $n$ , they are often used for testing numerical linear algebra code.

**Usage**

```
Hilbert(n)
```

**Arguments**

$n$  a non-negative integer.

**Value**

the  $n$  by  $n$  symmetric Hilbert matrix as a "dpoMatrix" object.

**See Also**

the class [dpoMatrix](#)

**Examples**

```
Hilbert(6)
```

---

|               |                                                |
|---------------|------------------------------------------------|
| image-methods | <i>Methods for image() in Package 'Matrix'</i> |
|---------------|------------------------------------------------|

---

**Description**

Methods for function [image](#) in package **Matrix**. An image of a matrix simply color codes all matrix entries and draws the  $n \times m$  matrix using an  $n \times m$  grid of (colored) rectangles.

The **Matrix** package image methods are based on [levelplot\(\)](#) from package **lattice**; hence these methods return an "object" of class "trellis", producing a graphic when (auto-) [print\(\)](#)ed.

**Usage**

```
S4 method for signature 'dgTMatrix'
image(x,
 xlim = c(1, di[2]),
 ylim = c(di[1], 1), aspect = "iso",
 sub = sprintf("Dimensions: %d x %d", di[1], di[2]),
 xlab = "Column", ylab = "Row", cuts = 15,
 useRaster = FALSE,
 useAbs = NULL, colorkey = !useAbs,
 col.regions = NULL,
 lwd = NULL, border.col = NULL, ...)
```

**Arguments**

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>               | a Matrix object, i.e., fulfilling <code>is(x, "Matrix")</code> .                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>xlim, ylim</code>      | x- and y-axis limits; may be used to “zoom into” matrix. Note that <i>x</i> , <i>y</i> “feel reversed”: <code>ylim</code> is for the rows (= 1st index) and <code>xlim</code> for the columns (= 2nd index). For convenience, when the limits are integer valued, they are both extended by 0.5; also, <code>ylim</code> is always used decreasingly.                                                                                                                |
| <code>aspect</code>          | aspect ratio specified as number ( <i>y</i> / <i>x</i> ) or string; see <code>levelplot</code> .                                                                                                                                                                                                                                                                                                                                                                     |
| <code>sub, xlab, ylab</code> | axis annotation with sensible defaults; see <code>plot.default</code> .                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>cuts</code>            | number of levels the range of matrix values would be divided into.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>useRaster</code>       | logical indicating if raster graphics should be used (instead of the tradition rectangle vector drawing). If true, <code>panel.levelplot.raster</code> (from <b>lattice</b> package) is used, and the colorkey is also done via rasters, see also <code>levelplot</code> and possibly <code>grid.raster</code> .<br>Note that using raster graphics may often be faster, but can be slower, depending on the matrix dimensions and the graphics device (dimensions). |
| <code>useAbs</code>          | logical indicating if <code>abs(x)</code> should be shown; if TRUE, the former (implicit) default, the default <code>col.regions</code> will be <code>grey</code> colors (and no colorkey drawn). The default is FALSE unless the matrix has no negative entries.                                                                                                                                                                                                    |
| <code>colorkey</code>        | logical indicating if a color key aka ‘legend’ should be produced. Default is to draw one, unless <code>useAbs</code> is true. You can also specify a <code>list</code> , see <code>levelplot</code> , such as <code>list(raster=TRUE)</code> in the case of rastering.                                                                                                                                                                                              |
| <code>col.regions</code>     | vector of gradually varying colors; see <code>levelplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>lwd</code>             | (only used when <code>useRaster</code> is false:) non-negative number or NULL (default), specifying the line-width of the rectangles of each non-zero matrix entry (drawn by <code>grid.rect</code> ). The default depends on the matrix dimension and the device size.                                                                                                                                                                                              |
| <code>border.col</code>      | color for the border of each rectangle. NA means no border is drawn. When NULL as by default, <code>border.col &lt;- if(lwd &lt; .01) NA else NULL</code> is used. Consider using an opaque color instead of NULL which corresponds to <code>grid::get.gpar("col")</code> .                                                                                                                                                                                          |
| <code>...</code>             | further arguments passed to methods and <code>levelplot</code> , notably at for specifying (possibly non equidistant) cut values for dividing the matrix values (superseding <code>cuts</code> above).                                                                                                                                                                                                                                                               |

**Value**

as all **lattice** graphics functions, `image(<Matrix>)` returns a “trellis” object, effectively the result of `levelplot()`.

**Methods**

All methods currently end up calling the method for the `dgTMatrix` class. Use `showMethods(image)` to list them all.

**See Also**

`levelplot`, and `print.trellis` from package **lattice**.

## Examples

```

showMethods(image)
And if you want to see the method definitions:
showMethods(image, includeDefs = TRUE, inherited = FALSE)

data(CAex, package = "Matrix")
image(CAex, main = "image(CAex)") -> imgC; imgC
stopifnot(!is.null(leg <- imgC$legend), is.list(leg$right)) # failed for 2 days ..
image(CAex, useAbs=TRUE, main = "image(CAex, useAbs=TRUE)")

cCA <- Cholesky(crossprod(CAex), Imult = .01)
See ?print.trellis --- place two image() plots side by side:
print(image(cCA, main="Cholesky(crossprod(CAex), Imult = .01)"),
 split=c(x=1,y=1,nx=2, ny=1), more=TRUE)
print(image(cCA, useAbs=TRUE),
 split=c(x=2,y=1,nx=2,ny=1))

data(USCounties, package = "Matrix")
image(USCounties)# huge
image(sign(USCounties))## just the pattern
how the result looks, may depend heavily on
the device, screen resolution, antialiasing etc
e.g. x11(type="Xlib") may show very differently than cairo-based

Drawing borders around each rectangle;
again, viewing depends very much on the device:
image(USCounties[1:400,1:200], lwd=.1)
Using (xlim,ylim) has advantage : matrix dimension and (col/row) indices:
image(USCounties, c(1,200), c(1,400), lwd=.1)
image(USCounties, c(1,300), c(1,200), lwd=.5)
image(USCounties, c(1,300), c(1,200), lwd=.01)
These 3 are all equivalent :
(I1 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE))
I2 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, border.col=NA)
I3 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=2, border.col=NA)
stopifnot(all.equal(I1, I2, check.environment=FALSE),
 all.equal(I2, I3, check.environment=FALSE))
using an opaque border color
image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=3, border.col = adjustcolor("skyblue", 1/2))

if(interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA"))) {
Using raster graphics: For PDF this would give a 77 MB file,
however, for such a large matrix, this is typically considerably
slower (than vector graphics rectangles) in most cases :
if(doPNG <- !dev.interactive())
 png("image-USCounties-raster.png", width=3200, height=3200)
image(USCounties, useRaster = TRUE) # should not suffer from anti-aliasing
if(doPNG)
 dev.off()
 ## and now look at the *.png image in a viewer you can easily zoom in and out
}#only if(doExtras)

```

Description

Class `index` is a virtual class designating index vectors, or “subscripts”, for (possibly named) vectors and arrays. It is typically used in signatures of methods for the subscript and subassignment operators, namely `[]` and `[]<-`. It is implemented as a *union* of the atomic vector classes `numeric`, `logical`, and `character`.

See Also

`[]`, `[]-methods`, and `[]<--methods`.

Examples

```
showClass("index")
```

---

|                 |                       |
|-----------------|-----------------------|
| indMatrix-class | <i>Index Matrices</i> |
|-----------------|-----------------------|

---

Description

The `indMatrix` class is the class of row and column *index* matrices, stored as 1-based integer index vectors. A row (column) index matrix is a matrix whose rows (columns) are standard unit vectors. Such matrices are useful when mapping observations to discrete sets of covariate values.

Multiplying a matrix on the left by a row index matrix is equivalent to indexing its rows, i.e., sampling the rows “with replacement”. Analogously, multiplying a matrix on the right by a column index matrix is equivalent to indexing its columns. Indeed, such products are implemented in **Matrix** as indexing operations; see ‘Details’ below.

A matrix whose rows *and* columns are standard unit vectors is called a *permutation* matrix. This special case is designated by the `pMatrix` class, a direct subclass of `indMatrix`.

Details

The transpose of an index matrix is an index matrix with identical `perm` but opposite margin. Hence the transpose of a row index matrix is a column index matrix, and vice versa.

The cross product of a row index matrix `R` and itself is a diagonal matrix whose diagonal entries are the the number of entries in each column of `R`.

Given a row index matrix `R` with `perm` slot `p`, a column index matrix `C` with `perm` slot `q`, and a matrix `M` with conformable dimensions, we have

$$\begin{array}{llll} RM & = & R \%*\% M & = & M[p, ] \\ MC & = & M \%*\% C & = & M[, q] \\ C' M & = & \text{crossprod}(C, M) & = & M[q, ] \\ MR' & = & \text{tcrossprod}(M, R) & = & M[, p] \\ R' R & = & \text{crossprod}(R) & = & \text{Diagonal}(x=\text{tabulate}(p, \text{ncol}(R))) \\ CC' & = & \text{tcrossprod}(C) & = & \text{Diagonal}(x=\text{tabulate}(q, \text{nrow}(C))) \end{array}$$

Operations on index matrices that result in index matrices will accordingly return an `indMatrix`. These include products of two column index matrices and (equivalently) column-indexing of a column index matrix (when dimensions are not dropped). Most other operations on `indMatrix` treat them as sparse nonzero pattern matrices (i.e., inheriting from virtual class `nsparseMatrix`). Hence vector-valued subsets of `indMatrix`, such as those given by `diag`, are always of type “`logical`”.

## Objects from the Class

Objects can be created explicitly with calls of the form `new("indMatrix", ...)`, but they are more commonly created by coercing 1-based integer index vectors, with calls of the form `as(., "indMatrix")`; see ‘Methods’ below.

## Slots

**margin** an integer, either 1 or 2, specifying whether the matrix is a row (1) or column (2) index.

**perm** a 1-based integer index vector, i.e., a vector of length `Dim[margin]` with elements taken from `1:Dim[1+margin%%2]`.

**Dim, Dimnames** inherited from virtual superclass `Matrix`.

## Extends

Classes `"sparseMatrix"` and `"generalMatrix"`, directly.

## Methods

**%%** signature(`x = "indMatrix"`, `y = "Matrix"`) and others listed by `showMethods("%*%", classes = "indMatrix")`: matrix products implemented where appropriate as indexing operations.

**coerce** signature(`from = "numeric"`, `to = "indMatrix"`): supporting typical `indMatrix` construction from a vector of positive integers. Row indexing is assumed.

**coerce** signature(`from = "list"`, `to = "indMatrix"`): supporting `indMatrix` construction for row *and* column indexing, including index vectors of length 0 and index vectors whose maximum is less than the number of rows or columns being indexed.

**coerce** signature(`from = "indMatrix"`, `to = "matrix"`): coercion to a traditional `matrix` of `logical` type, with `FALSE` and `TRUE` in place of 0 and 1.

**t** signature(`x = "indMatrix"`): the transpose, which is an `indMatrix` with identical `perm` but opposite `margin`.

**rowSums, rowMeans, colSums, colMeans** signature(`x = "indMatrix"`): row and column sums and means.

**rbind2, cbind2** signature(`x = "indMatrix"`, `y = "indMatrix"`): row-wise catenation of two row index matrices with equal numbers of columns and column-wise catenation of two column index matrices with equal numbers of rows.

**kronecker** signature(`X = "indMatrix"`, `Y = "indMatrix"`): Kronecker product of two row index matrices or two column index matrices, giving the row or column index matrix corresponding to their “interaction”.

## Author(s)

Fabian Scheipl at ‘uni-muenchen.de’, building on the existing class `pMatrix` after a nice hike’s conversation with Martin Maechler. Methods for `crossprod(x, y)` and `kronecker(x, y)` with both arguments inheriting from `indMatrix` were made considerably faster thanks to a suggestion by Boris Vaillant. Diverse tweaks by Martin Maechler and Mikael Jagan, notably the latter’s implementation of `margin`, prior to which the `indMatrix` class was designated only for row index matrices.

**See Also**

Subclass [pMatrix](#) of permutation matrices, a special case of index matrices; virtual class [nMatrix](#) of nonzero pattern matrices, and its subclasses.

**Examples**

```
p1 <- as(c(2,3,1), "pMatrix")
(sm1 <- as(rep(c(2,3,1), e=3), "indMatrix"))
stopifnot(all(sm1 == p1[rep(1:3, each=3),]))

row-indexing of a <pMatrix> turns it into an <indMatrix>:
class(p1[rep(1:3, each=3),])

set.seed(12) # so we know '10' is in sample
random index matrix for 30 observations and 10 unique values:
(s10 <- as(sample(10, 30, replace=TRUE), "indMatrix"))

Sample rows of a numeric matrix :
(mm <- matrix(1:10, nrow=10, ncol=3))
s10 %*% mm

set.seed(27)
IM1 <- as(sample(1:20, 100, replace=TRUE), "indMatrix")
IM2 <- as(sample(1:18, 100, replace=TRUE), "indMatrix")
(c12 <- crossprod(IM1, IM2))
same as cross-tabulation of the two index vectors:
stopifnot(all(c12 - unclass(table(IM1@perm, IM2@perm)) == 0))

3 observations, 4 implied values, first does not occur in sample:
as(2:4, "indMatrix")
3 observations, 5 values, first and last do not occur in sample:
as(list(2:4, 5), "indMatrix")

as(sm1, "nMatrix")

invertPerm

*Utilities for Permutation Vectors***Description**

invertPerm and signPerm compute the inverse and sign of a length-n permutation vector. isPerm tests if a length-n integer vector is a valid permutation vector. asPerm coerces a length-m transposition vector to a length-n permutation vector, where  $m \leq n$ .

**Usage**

```
invertPerm(p, off = 1L, ioff = 1L)
signPerm(p, off = 1L)
isPerm(p, off = 1L)
asPerm(pivot, off = 1L, ioff = 1L, n = length(pivot))

invPerm(p, zero.p = FALSE, zero.res = FALSE)
```

**Arguments**

|                       |                                                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>p</code>        | an integer vector of length <code>n</code> .                                                                                                                                                                      |
| <code>pivot</code>    | an integer vector of length <code>m</code> .                                                                                                                                                                      |
| <code>off</code>      | an integer offset, indicating that <code>p</code> is a permutation of <code>off+0:(n-1)</code> or that <code>pivot</code> contains <code>m</code> values sampled with replacement from <code>off+0:(n-1)</code> . |
| <code>ioff</code>     | an integer offset, indicating that the result should be a permutation of <code>ioff+0:(n-1)</code> .                                                                                                              |
| <code>n</code>        | a integer greater than or equal to <code>m</code> , indicating the length of the result. Transpositions are applied to a permutation vector initialized as <code>seq_len(n)</code> .                              |
| <code>zero.p</code>   | a logical. Equivalent to <code>off=0</code> if TRUE and <code>off=1</code> if FALSE.                                                                                                                              |
| <code>zero.res</code> | a logical. Equivalent to <code>ioff=0</code> if TRUE and <code>ioff=1</code> if FALSE.                                                                                                                            |

**Details**

`invertPerm(p, off, ioff=1)` is equivalent to `order(p)` or `sort.list(p)` for all values of `off`. For the default value `off=1`, it returns the value of `p` after `p[p] <- seq_along(p)`.

`invPerm` is a simple wrapper around `invertPerm`, retained for backwards compatibility.

**Value**

By default, i.e., with `off=1` and `ioff=1`:

`invertPerm(p)` returns an integer vector of length `length(p)` such that `p[invertPerm(p)]` and `invertPerm(p)[p]` are both `seq_along(p)`, i.e., the identity permutation.

`signPerm(p)` returns 1 if `p` is an even permutation and -1 otherwise (i.e., if `p` is odd).

`isPerm(p)` returns TRUE if `p` is a permutation of `seq_along(p)` and FALSE otherwise.

`asPerm(pivot)` returns the result of transposing elements `i` and `pivot[i]` of a permutation vector initialized as `seq_len(n)`, for `i` in `seq_along(pivot)`.

**See Also**

Class `pMatrix` of permutation matrices.

**Examples**

```
p <- sample(10L) # a random permutation vector
ip <- invertPerm(p)
s <- signPerm(p)

'p' and 'ip' are indeed inverses:
stopifnot(exprs = {
 isPerm(p)
```

```

isPerm(ip)
identical(s, 1L) || identical(s, -1L)
identical(s, signPerm(ip))
identical(p[ip], 1:10)
identical(ip[p], 1:10)
identical(invertPerm(ip), p)
})

Product of transpositions (1 2)(2 1)(4 3)(6 8)(10 1) = (3 4)(6 8)(1 10)
pivot <- c(2L, 1L, 3L, 3L, 5L, 8L, 7L, 8L, 9L, 1L)
q <- asPerm(pivot)
stopifnot(exprs = {
 identical(q, c(10L, 2L, 4L, 3L, 5L, 8L, 7L, 6L, 9L, 1L))
 identical(q[q], seq_len(10L)) # because the permutation is odd:
 signPerm(q) == -1L
})

invPerm # a less general version of 'invertPerm'

```

---

is.na-methods

is.na(), is.finite() Methods for 'Matrix' Objects

---

## Description

Methods for generic functions [anyNA\(\)](#), [is.na\(\)](#), [is.nan\(\)](#), [is.infinite\(\)](#), and [is.finite\(\)](#), for objects inheriting from virtual class [Matrix](#) or [sparseVector](#).

## Usage

```

S4 method for signature 'denseMatrix'
is.na(x)
S4 method for signature 'sparseMatrix'
is.na(x)
S4 method for signature 'diagonalMatrix'
is.na(x)
S4 method for signature 'indMatrix'
is.na(x)
S4 method for signature 'sparseVector'
is.na(x)
...
and likewise for anyNA, is.nan, is.infinite, is.finite

```

## Arguments

**x** an R object, here a sparse or dense matrix or vector.

## Value

For [is.\\*\(\)](#), an [nMatrix](#) or [nsparseVector](#) matching the dimensions of **x** and specifying the positions in **x** of (some subset of) [NA](#), [NaN](#), [Inf](#), and [-Inf](#). For [anyNA\(\)](#), TRUE if **x** contains NA or NaN and FALSE otherwise.

**See Also**[NA](#), [NaN](#), [Inf](#)**Examples**

```
(M <- Matrix(1:6, nrow = 4, ncol = 3,
 dimnames = list(letters[1:4], LETTERS[1:3])))
stopifnot(!anyNA(M), !any(is.na(M)))

M[2:3, 2] <- NA
(inM <- is.na(M))
stopifnot(anyNA(M), sum(inM) == 2)

(A <- spMatrix(nrow = 10, ncol = 20,
 i = c(1, 3:8), j = c(2, 9, 6:10), x = 7 * (1:7)))
stopifnot(!anyNA(A), !any(is.na(A)))

A[2, 3] <- A[1, 2] <- A[5, 5:9] <- NA
(inA <- is.na(A))
stopifnot(anyNA(A), sum(inA) == 1 + 1 + 5)
```

is.null.DN

*Are the Dimnames dn NULL-like ?***Description**

Are the [dimnames](#) dn [NULL](#)-like?

`is.null.DN(dn)` is less strict than `is.null(dn)`, because it is also true ([TRUE](#)) when the dimnames dn are “like” `NULL`, or `list(NULL, NULL)`, as they can easily be for the traditional R matrices ([matrix](#)) which have no formal [class](#) definition, and hence much freedom in how their [dimnames](#) look like.

**Usage**

```
is.null.DN(dn)
```

**Arguments**

dn                    [dimnames](#)() of a [matrix](#)-like R object.

**Value**

[logical](#) [TRUE](#) or [FALSE](#).

**Note**

This function is really to be used on “traditional” matrices rather than those inheriting from [Matrix](#), as the latter will always have `dimnames list(NULL, NULL)` exactly, in such a case.

**Author(s)**

Martin Maechler

**See Also**

[is.null](#), [dimnames](#), [matrix](#).

**Examples**

```
m1 <- m2 <- m3 <- m4 <- m <-
 matrix(round(100 * rnorm(6)), 2, 3)
dimnames(m1) <- list(NULL, NULL)
dimnames(m2) <- list(NULL, character())
dimnames(m3) <- rev(dimnames(m2))
dimnames(m4) <- rep(list(character()),2)

m4 # prints absolutely identically to m

c.o <- capture.output
cm <- c.o(m)
stopifnot(exprs = {
 m == m1; m == m2; m == m3; m == m4
 identical(cm, c.o(m1)); identical(cm, c.o(m2))
 identical(cm, c.o(m3)); identical(cm, c.o(m4))
})

hasNoDimnames <- function(.) is.null.DN(dimnames(.))
stopifnot(exprs = {
 hasNoDimnames(m)
 hasNoDimnames(m1); hasNoDimnames(m2)
 hasNoDimnames(m3); hasNoDimnames(m4)
 hasNoDimnames(Matrix(m) -> M)
 hasNoDimnames(as(M, "sparseMatrix"))
})
```

---

isSymmetric-methods      *Methods for Function 'isSymmetric' in Package 'Matrix'*

---

**Description**

`isSymmetric` tests whether its argument is a symmetric square matrix, by default tolerating some numerical fuzz and requiring symmetric [dD]imnames in addition to symmetry in the mathematical sense. `isSymmetric` is a generic function in **base**, which has a [method](#) for traditional matrices of implicit [class](#) `"matrix"`. Methods are defined here for various proper and virtual classes in **Matrix**, so that `isSymmetric` works for all objects inheriting from virtual class `"Matrix"`.

**Usage**

```
S4 method for signature 'denseMatrix'
isSymmetric(object, checkDN = TRUE, ...)
S4 method for signature 'CsparseMatrix'
isSymmetric(object, checkDN = TRUE, ...)
S4 method for signature 'RsparseMatrix'
isSymmetric(object, checkDN = TRUE, ...)
S4 method for signature 'TsparseMatrix'
isSymmetric(object, checkDN = TRUE, ...)
S4 method for signature 'diagonalMatrix'
```

```

isSymmetric(object, checkDN = TRUE, ...)
S4 method for signature 'indMatrix'
isSymmetric(object, checkDN = TRUE, ...)
S4 method for signature 'dgeMatrix'
isSymmetric(object, checkDN = TRUE, tol = 100 * .Machine$double.eps, tol1 = 8 * tol, ...)
S4 method for signature 'dgCMatrix'
isSymmetric(object, checkDN = TRUE, tol = 100 * .Machine$double.eps, ...)

```

### Arguments

|           |                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | a "Matrix".                                                                                                                                        |
| checkDN   | a <a href="#">logical</a> indicating whether symmetry of the Dimnames <a href="#">slot</a> of object should be checked.                            |
| tol, tol1 | numerical tolerances allowing <i>approximate</i> symmetry of numeric (rather than logical) matrices. See also <a href="#">isSymmetric.matrix</a> . |
| ...       | further arguments passed to methods (typically methods for <a href="#">all.equal</a> ).                                                            |

### Details

The Dimnames [slot](#) of object, say dn, is considered to be symmetric if and only if

- dn[[1]] and dn[[2]] are identical *or* one is NULL; *and*
- ndn <- names(dn) is NULL *or* ndn[1] and ndn[2] are identical *or* one is the empty string "".

Hence list(a=nms, a=nms) is considered to be *symmetric*, and so too are list(a=nms, NULL) and list(NULL, a=nms).

Note that this definition is *looser* than that employed by [isSymmetric.matrix](#), which requires dn[1] and dn[2] to be identical, where dn is the dimnames [attribute](#) of a traditional matrix.

### Value

A [logical](#), either TRUE or FALSE (never NA).

### See Also

[forceSymmetric](#); [symmpart](#) and [skewpart](#); virtual class "[symmetricMatrix](#)" and its subclasses.

### Examples

```

isSymmetric(Diagonal(4)) # TRUE of course
M <- Matrix(c(1,2,2,1), 2,2)
isSymmetric(M) # TRUE (*and* of formal class "dsyMatrix")
isSymmetric(as(M, "generalMatrix")) # still symmetric, even if not "formally"
isSymmetric(triu(M)) # FALSE

Look at implementations:
showMethods("isSymmetric", includeDefs = TRUE) # includes S3 generic from base

```

---

isTriangular-methods    *Test whether a Matrix is Triangular or Diagonal*

---

**Description**

isTriangular and isDiagonal test whether their argument is a triangular or diagonal matrix, respectively. Unlike the analogous `isSymmetric`, these two functions are generically from **Matrix** rather than base. Hence **Matrix** defines methods for traditional matrices of implicit class `"matrix"` in addition to matrices inheriting from virtual class `"Matrix"`.

By our definition, triangular and diagonal matrices are *square*, i.e., they have the same number of rows and columns.

**Usage**

```
isTriangular(object, upper = NA, ...)
```

```
isDiagonal(object)
```

**Arguments**

|        |                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an R object, typically a matrix.                                                                                                                                                                                                     |
| upper  | a <a href="#">logical</a> , either TRUE or FALSE, in which case TRUE is returned only for upper or lower triangular object; or otherwise <a href="#">NA</a> (the default), in which case TRUE is returned for any triangular object. |
| ...    | further arguments passed to methods (currently unused by <b>Matrix</b> ).                                                                                                                                                            |

**Value**

A [logical](#), either TRUE or FALSE (never [NA](#)).

If object is triangular and upper is NA, then isTriangular returns TRUE with an [attribute](#) kind, either "U" or "L", indicating that object is **upper** or **lower** triangular, respectively. Users should not rely on how kind is determined for diagonal matrices, which are both upper and lower triangular.

**See Also**

[isSymmetric](#); virtual classes `"triangularMatrix"` and `"diagonalMatrix"` and their subclasses.

**Examples**

```
isTriangular(Diagonal(4))
is TRUE: a diagonal matrix is also (both upper and lower) triangular
(M <- Matrix(c(1,2,0,1), 2,2))
isTriangular(M) # TRUE (*and* of formal class "dtrMatrix")
isTriangular(as(M, "generalMatrix")) # still triangular, even if not "formally"
isTriangular(crossprod(M)) # FALSE

isDiagonal(matrix(c(2,0,0,1), 2,2)) # TRUE

Look at implementations:
showMethods("isTriangular", includeDefs = TRUE)
showMethods("isDiagonal", includeDefs = TRUE)
```

---

|           |                                  |
|-----------|----------------------------------|
| KhatriRao | <i>Khatri-Rao Matrix Product</i> |
|-----------|----------------------------------|

---

**Description**

Computes Khatri-Rao products for any kind of matrices.

The Khatri-Rao product is a column-wise Kronecker product. Originally introduced by Khatri and Rao (1968), it has many different applications, see Liu and Trenkler (2008) for a survey. Notably, it is used in higher-dimensional tensor decompositions, see Bader and Kolda (2008).

**Usage**

```
KhatriRao(X, Y = X, FUN = "*", sparseY = TRUE, make.dimnames = FALSE)
```

**Arguments**

|               |                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X, Y          | matrices of with the same number of columns.                                                                                                                          |
| FUN           | the (name of the) <a href="#">function</a> to be used for the column-wise Kronecker products, see <a href="#">kronecker</a> , defaulting to the usual multiplication. |
| sparseY       | logical specifying if Y should be coerced and treated as <a href="#">sparseMatrix</a> . Set this to FALSE, e.g., to distinguish structural zeros from zero entries.   |
| make.dimnames | logical indicating if the result should inherit <a href="#">dimnames</a> from X and Y in a simple way.                                                                |

**Value**

a "[CsparseMatrix](#)", say R, the Khatri-Rao product of X ( $n \times k$ ) and Y ( $m \times k$ ), is of dimension  $(n \cdot m) \times k$ , where the j-th column,  $R[, j]$  is the kronecker product [kronecker](#)( $X[, j]$ ,  $Y[, j]$ ).

**Note**

The current implementation is efficient for large sparse matrices.

**Author(s)**

Original by Michael Cysouw, Univ. Marburg; minor tweaks, bug fixes etc, by Martin Maechler.

## Examples

```
Example with very small matrices:
m <- matrix(1:12,3,4)
d <- diag(1:4)
KhatriRao(m,d)
KhatriRao(d,m)
dimnames(m) <- list(LETTERS[1:3], letters[1:4])
KhatriRao(m,d, make.dimnames=TRUE)
KhatriRao(d,m, make.dimnames=TRUE)
dimnames(d) <- list(NULL, paste0("D", 1:4))
KhatriRao(m,d, make.dimnames=TRUE)
KhatriRao(d,m, make.dimnames=TRUE)
dimnames(d) <- list(paste0("d", 10*1:4), paste0("D", 1:4))
(Kmd <- KhatriRao(m,d, make.dimnames=TRUE))
(Kdm <- KhatriRao(d,m, make.dimnames=TRUE))

nm <- as(m, "nsparseMatrix")
nd <- as(d, "nsparseMatrix")
KhatriRao(nm,nd, make.dimnames=TRUE)
KhatriRao(nd,nm, make.dimnames=TRUE)

stopifnot(dim(KhatriRao(m,d)) == c(nrow(m)*nrow(d), ncol(d)))
border cases / checks:
zm <- nm; zm[] <- FALSE # all FALSE matrix
stopifnot(all(K1 <- KhatriRao(nd, zm) == 0), identical(dim(K1), c(12L, 4L)),
 all(K2 <- KhatriRao(zm, nd) == 0), identical(dim(K2), c(12L, 4L)))

d0 <- d; d0[] <- 0; m0 <- Matrix(d0[-1,])
stopifnot(all(K3 <- KhatriRao(d0, m) == 0), identical(dim(K3), dim(Kdm)),
 all(K4 <- KhatriRao(m, d0) == 0), identical(dim(K4), dim(Kmd)),
 all(KhatriRao(d0, d0) == 0), all(KhatriRao(m0, d0) == 0),
 all(KhatriRao(d0, m0) == 0), all(KhatriRao(m0, m0) == 0),
 identical(dimnames(KhatriRao(m, d0, make.dimnames=TRUE)), dimnames(Kmd)))

a matrix with "structural" and non-structural zeros:
m01 <- new("dgCMatrix", i = c(0L, 2L, 0L, 1L), p = c(0L, 0L, 0L, 2L, 4L),
 Dim = 3:4, x = c(1, 0, 1, 0))
D4 <- Diagonal(4, x=1:4) # "as" d
DU <- Diagonal(4)# unit-diagonal: uplo="U"
(K5 <- KhatriRao(d, m01))
K5d <- KhatriRao(d, m01, sparseY=FALSE)
K5Dd <- KhatriRao(D4, m01, sparseY=FALSE)
K5Ud <- KhatriRao(DU, m01, sparseY=FALSE)
(K6 <- KhatriRao(diag(3), t(m01)))
K6D <- KhatriRao(Diagonal(3), t(m01))
K6d <- KhatriRao(diag(3), t(m01), sparseY=FALSE)
K6Dd <- KhatriRao(Diagonal(3), t(m01), sparseY=FALSE)
stopifnot(exprs = {
 all(K5 == K5d)
 identical(cbind(c(7L, 10L), c(3L, 4L)),
 which(K5 != 0, arr.ind = TRUE, useNames=FALSE))
 identical(K5d, K5Dd)
 identical(K6, K6D)
 all(K6 == K6d)
 identical(cbind(3:4, 1L),
 which(K6 != 0, arr.ind = TRUE, useNames=FALSE))
})
```

```
 identical(K6d, K6Dd)
 })
```

*Koenker-Ng Example Sparse Model Matrix and Response Vector*

## Description

A model matrix `mm` and corresponding response vector `y` used in an example by Koenker and Ng. The matrix `mm` is a sparse matrix with 1850 rows and 712 columns but only 8758 non-zero entries. It is a "dgCMatrix" object. The vector `y` is just `numeric` of length 1850.

## Usage

```
data(KNex)
```

## References

Roger Koenker and Pin Ng (2003). SparseM: A sparse matrix package for R; *J. of Statistical Software*, **8** (6), [doi:10.18637/jss.v008.i06](https://doi.org/10.18637/jss.v008.i06)

## Examples

```
data(KNex, package = "Matrix")
class(KNex$mm)
dim(KNex$mm)
image(KNex$mm)
str(KNex)

system.time(# a fraction of a second
 sparse.sol <- with(KNex, solve(crossprod(mm), crossprod(mm, y))))

head(round(sparse.sol,3))

Compare with QR-based solution ("more accurate, but slightly slower"):
system.time(
 sp.sol2 <- with(KNex, qr.coef(qr(mm), y)))

all.equal(sparse.sol, sp.sol2, tolerance = 1e-13) # TRUE
```

kronecker-methods

*Methods for Function 'kronecker()' in Package 'Matrix'*

## Description

Computes Kronecker products for objects inheriting from "Matrix".

In order to preserve sparseness, we treat  $0 * NA$  as  $0$ , not as `NA` as usually in R (and as used for the `base` function `kronecker`).

**Methods**

```

kronecker signature(X = "Matrix", Y = "ANY")
kronecker signature(X = "ANY", Y = "Matrix")
kronecker signature(X = "diagonalMatrix", Y = "ANY")
kronecker signature(X = "sparseMatrix", Y = "ANY")
kronecker signature(X = "TsparseMatrix", Y = "TsparseMatrix")
kronecker signature(X = "dgTMatrix", Y = "dgTMatrix")
kronecker signature(X = "dtTMatrix", Y = "dtTMatrix")
kronecker signature(X = "indMatrix", Y = "indMatrix")

```

**Examples**

```

(t1 <- spMatrix(5,4, x= c(3,2,-7,11), i= 1:4, j=4:1)) # 5 x 4
(t2 <- kronecker(Diagonal(3, 2:4), t1)) # 15 x 12

should also work with special-cased logical matrices
l3 <- upper.tri(matrix(,3,3))
M <- Matrix(l3)
(N <- as(M, "nsparseMatrix")) # "ntCMatrix" (upper triangular)
N2 <- as(N, "generalMatrix") # (lost "t"riangularity)
MM <- kronecker(M,M)
NN <- kronecker(N,N) # "dtTMatrix" i.e. did keep
NN2 <- kronecker(N2,N2)
stopifnot(identical(NN,MM),
 is(NN2, "sparseMatrix"), all(NN2 == NN),
 is(NN, "triangularMatrix"))

```

|--------------------|---------------------------------------------------------------|
| ldenseMatrix-class | <i>Virtual Class "ldenseMatrix" of Dense Logical Matrices</i> |
|--------------------|---------------------------------------------------------------|

---

**Description**

ldenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both [denseMatrix](#) and [lMatrix](#) directly.

**Slots**

**x:** logical vector containing the entries of the matrix.  
**Dim, Dimnames:** see [Matrix](#).

**Extends**

Class "lMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "lMatrix".  
 Class "Matrix", by class "denseMatrix".

**Methods**

```

as.vector signature(x = "ldenseMatrix", mode = "missing"): ...
which signature(x = "ndenseMatrix"), semantically equivalent to base function which(x,
arr.ind); for details, see the lMatrix class documentation.

```

**See Also**

Class [lgeMatrix](#) and the other subclasses.

**Examples**

```
showClass("ldenseMatrix")
as(diag(3) > 0, "ldenseMatrix")
```

---

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| lDiMatrix-class | <i>Class "lDiMatrix" of Diagonal Logical Matrices</i> |
|-----------------|-------------------------------------------------------|

---

**Description**

The class "lDiMatrix" of logical diagonal matrices.

**Objects from the Class**

Objects can be created by calls of the form `new("lDiMatrix", ...)` but typically rather via [Diagonal](#).

**Slots**

**x:** "logical" vector.  
**diag:** "character" string, either "U" or "N", see [ddiMatrix](#).  
**Dim,Dimnames:** matrix dimension and [dimnames](#), see the [Matrix](#) class description.

**Extends**

Class "[diagonalMatrix](#)" and class "[lMatrix](#)", directly.  
 Class "[sparseMatrix](#)", by class "[diagonalMatrix](#)".

**See Also**

Classes [ddiMatrix](#) and [diagonalMatrix](#); function [Diagonal](#).

**Examples**

```
(lM <- Diagonal(x = c(TRUE,FALSE,FALSE)))
str(lM)#> gory details (slots)

crossprod(lM) # numeric
(nM <- as(lM, "nMatrix"))
crossprod(nM) # pattern sparse
```

lgeMatrix-class

Class "lgeMatrix" of General Dense Logical Matrices

## Description

This is the class of general dense [logical](#) matrices.

## Slots

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Class "ldenseMatrix", directly. Class "lMatrix", by class "ldenseMatrix". Class "denseMatrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix".

## Methods

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#)); use, e.g., [showMethods\(class="lgeMatrix"\)](#) for details.

## See Also

Non-general logical dense matrix classes such as [ltrMatrix](#), or [lsyMatrix](#); *sparse* logical classes such as [lgCMatrix](#).

## Examples

```
showClass("lgeMatrix")
str(new("lgeMatrix"))
set.seed(1)
(lM <- Matrix(matrix(rnorm(28), 4,7) > 0))# a simple random lgeMatrix
set.seed(11)
(lC <- Matrix(matrix(rnorm(28), 4,7) > 0))# a simple random lgCMatrix
as(lM, "CsparseMatrix")
```

---

lsparseMatrix-class     *Sparse logical matrices*

---

## Description

The `lsparseMatrix` class is a virtual class of logical sparse matrices, i.e., sparse matrices with entries TRUE, FALSE, or NA.

These can be stored in the “triplet” form (class `TsparseMatrix`, subclasses `lgTMatrix`, `lsTMatrix`, and `ltTMatrix`) or in compressed column-oriented form (class `CsparseMatrix`, subclasses `lgCMatrix`, `lsCMatrix`, and `ltCMatrix`) or—rarely—in compressed row-oriented form (class `RsparseMatrix`, subclasses `lgRMatrix`, `lsRMatrix`, and `ltRMatrix`). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

## Details

Note that triplet stored (`TsparseMatrix`) matrices such as `lgTMatrix` may contain duplicated pairs of indices  $(i, j)$  as for the corresponding numeric class `dgTMatrix` where for such pairs, the corresponding x slot entries are added. For logical matrices, the x entries corresponding to duplicated index pairs  $(i, j)$  are “added” as well if the addition is defined as logical *or*, i.e., “TRUE + TRUE  $\rightarrow$  TRUE” and “TRUE + FALSE  $\rightarrow$  TRUE”. Note the use of `asUniqueT()` for getting an internally unique representation without duplicated  $(i, j)$  entries.

## Objects from the Class

Objects can be created by calls of the form `new("lgCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the logical form, e.g. in an expression `x != 0`.

The logical form is also used in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence any numeric sparse matrices can be treated as logical sparse matrices.

## Slots

- x:** Object of class "logical", i.e., either TRUE, NA, or FALSE.
- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when diag is "U". Present in the triangular classes only.
- p:** Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- i:** Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- j:** Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed row-oriented forms only.

**Dim:** Object of class "integer" - the dimensions of the matrix.

## Methods

**coerce** signature(from = "dgMatrix", to = "lgMatrix")

**t** signature(x = "lgMatrix"): returns the transpose of x

**which** signature(x = "lsparseMatrix"), semantically equivalent to **base** function **which**(x, arr.ind); for details, see the **lMatrix** class documentation.

## See Also

the class **dgMatrix** and **dgTMatrix**

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
(lm <- (m > 1)) # lgC
!lm # no longer sparse
stopifnot(is(lm,"lsparseMatrix"),
 identical(!lm, m <= 1))

data(KNex, package = "Matrix")
str(mmG.1 <- (KNex $ mm) > 0.1)# "lgC..."
table(mmG.1@x)# however with many ``non-structural zeros''
from logical to nz_pattern -- okay when there are no NA's :
nmG.1 <- as(mmG.1, "nMatrix") # <<< has "TRUE" also where mmG.1 had FALSE
from logical to "double"
dmG.1 <- as(mmG.1, "dMatrix") # has '0' and back:
lmG.1 <- as(dmG.1, "lMatrix")
stopifnot(identical(nmG.1, as((KNex $ mm) != 0,"nMatrix")),
 validObject(lmG.1),
 identical(lmG.1, mmG.1))

class(xnx <- crossprod(nmG.1))# "nsC.."
class(xlx <- crossprod(mmG.1))# "dsC.." : numeric
is0 <- (xlx == 0)
mean(as.vector(is0))# 99.3% zeros: quite sparse, but
table(xlx@x == 0)# more than half of the entries are (non-structural!) 0
stopifnot(isSymmetric(xlx), isSymmetric(xnx),
 ## compare xnx and xlx : have the *same* non-structural 0s :
 sapply(slotNames(xnx),
 function(n) identical(slot(xnx, n), slot(xlx, n)))))
```

---

lsyMatrix-class

---

Symmetric Dense Logical Matrices

---

## Description

The "lsyMatrix" class is the class of symmetric, dense logical matrices in non-packed storage and "lspMatrix" is the class of these in packed storage. In the packed form, only the upper triangle or the lower triangle is stored.

## Objects from the Class

Objects can be created by calls of the form `new("lsyMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Both extend classes "[ldenseMatrix](#)" and "[symmetricMatrix](#)", directly; further, class "[Matrix](#)" and others, *indirectly*. Use [showClass](#)("lsyMatrix"), e.g., for details.

## Methods

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#); use, e.g., [showMethods](#)(class="lsyMatrix") for details.

## See Also

[lgeMatrix](#), [Matrix](#), [t](#)

## Examples

```
(M2 <- Matrix(c(TRUE, NA, FALSE, FALSE), 2, 2)) # logical dense (ltr)
str(M2)
can
(sM <- M2 | t(M2)) # "lge"
as(sM, "symmetricMatrix")
str(sM <- as(sM, "packedMatrix")) # packed symmetric
```

---

ltrMatrix-class

*Triangular Dense Logical Matrices*

---

## Description

The "[ltrMatrix](#)" class is the class of triangular, dense, logical matrices in nonpacked storage. The "[ltpMatrix](#)" class is the same except in packed storage.

**Slots**

- x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.
- factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Both extend classes "[ldenseMatrix](#)" and "[triangularMatrix](#)", directly; further, class "[Matrix](#)", "[lMatrix](#)" and others, *indirectly*. Use [showClass\("ltrMatrix"\)](#), e.g., for details.

**Methods**

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#); use, e.g., [showMethods\(class="ltrMatrix"\)](#) for details.

**See Also**

Classes [lgeMatrix](#), [Matrix](#); function [t](#)

**Examples**

```
showClass("ltrMatrix")

str(new("ltpMatrix"))
(lutr <- as(upper.tri(matrix(, 4, 4)), "ldenseMatrix"))
str(lutp <- pack(lutr)) # packed matrix: only 10 = 4*(4+1)/2 entries
!lutp # the logical negation (is *not* logical triangular !)
but this one is:
stopifnot(all.equal(lutp, pack(!lutp)))
```

---

lu-methods

---

*Methods for LU Factorization*

---

**Description**

Computes the pivoted LU factorization of an  $m \times n$  real matrix  $A$ , which has the general form

$$P_1 A P_2 = LU$$

or (equivalently)

$$A = P_1' L U P_2'$$

where  $P_1$  is an  $m \times m$  permutation matrix,  $P_2$  is an  $n \times n$  permutation matrix,  $L$  is an  $m \times \min(m, n)$  unit lower trapezoidal matrix, and  $U$  is a  $\min(m, n) \times n$  upper trapezoidal matrix.

Methods for [denseMatrix](#) are built on LAPACK routine `dgetrf`, which does not permute columns, so that  $P_2$  is an identity matrix.

Methods for [sparseMatrix](#) are built on CXSparse routine `cs_lu`, which requires  $m = n$ , so that  $L$  and  $U$  are triangular matrices.

### Usage

```
lu(x, ...)
S4 method for signature 'dgeMatrix'
lu(x, warnSing = TRUE, ...)
S4 method for signature 'dgCMatrix'
lu(x, errSing = TRUE, order = NA_integer_,
 tol = 1, ...)
S4 method for signature 'dsyMatrix'
lu(x, cache = TRUE, ...)
S4 method for signature 'dsCMatrix'
lu(x, cache = TRUE, ...)
S4 method for signature 'matrix'
lu(x, ...)
```

### Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | a <a href="#">finite</a> matrix or <a href="#">Matrix</a> to be factorized, which must be square if sparse.                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>warnSing</code> | a logical indicating if a <a href="#">warning</a> should be signaled for singular <code>x</code> . Used only by methods for dense matrices.                                                                                                                                                                                                                                                                                                                                                          |
| <code>errSing</code>  | a logical indicating if an <a href="#">error</a> should be signaled for singular <code>x</code> . Used only by methods for sparse matrices.                                                                                                                                                                                                                                                                                                                                                          |
| <code>order</code>    | an integer in <code>0:3</code> passed to CXSparse routine <code>cs_sqr</code> , indicating a strategy for choosing the column permutation $P_2$ . 0 means no column permutation. 1, 2, and 3 indicate a fill-reducing ordering of $A + A'$ , $\tilde{A}'\tilde{A}$ , and $A'A$ , where $\tilde{A}$ is $A$ with “dense” rows removed. NA (the default) is equivalent to 2 if <code>tol == 1</code> and 1 otherwise. Do not set to 0 unless you know that the column order of $A$ is already sensible. |
| <code>tol</code>      | a number. The original pivot element is used if its absolute value exceeds <code>tol * a</code> , where <code>a</code> is the maximum in absolute value of the other possible pivot elements. Set <code>tol &lt; 1</code> only if you know what you are doing.                                                                                                                                                                                                                                       |
| <code>cache</code>    | a logical indicating if the result should be cached in <code>x@factors[["LU"]]</code> . Note that caching is experimental and that only methods for classes extending <a href="#">generalMatrix</a> or <a href="#">symmetricMatrix</a> will have this argument.                                                                                                                                                                                                                                      |
| <code>...</code>      | further arguments passed to or from methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Details

What happens when `x` is determined to be near-singular differs by method. The method for class [dgeMatrix](#) completes the factorization, warning if `warnSing = TRUE` and in any case returning a valid [denseLU](#) object. Users of this method can detect singular `x` with a suitable warning handler; see [tryCatch](#). In contrast, the method for class [dgCMatrix](#) abandons further computation, throwing an error if `errSing = TRUE` and otherwise returning NA. Users of this method can detect singular `x` with an error handler or by setting `errSing = FALSE` and testing for a formal result with `is(, "sparseLU")`.

**Value**

An object representing the factorization, inheriting from virtual class `LU`. The specific class is `denseLU` unless `x` inherits from virtual class `sparseMatrix`, in which case it is `sparseLU`.

Classes `dgeMatrix` and `dgCMatrix`.

Generic functions `expand1` and `expand2`, for constructing matrix factors from the result.

Generic functions `Cholesky`, `BunchKaufman`, `Schur`, and `qr`, for computing other factorizations.

**Examples**

```
showMethods("lu", inherited = FALSE)
set.seed(0)

---- Dense -----

(A1 <- Matrix(rnorm(9L), 3L, 3L))
(lu.A1 <- lu(A1))

(A2 <- round(10 * A1[, -3L]))
(lu.A2 <- lu(A2))

A ~ P1' L U in floating point
str(e.lu.A2 <- expand2(lu.A2), max.level = 2L)
stopifnot(all.equal(A2, Reduce(`%*%`, e.lu.A2)))

---- Sparse -----

A3 <- as(readMM(system.file("external/pores_1.mtx", package = "Matrix")),
 "CsparseMatrix")
(lu.A3 <- lu(A3))

A ~ P1' L U P2' in floating point
str(e.lu.A3 <- expand2(lu.A3), max.level = 2L)
stopifnot(all.equal(A3, Reduce(`%*%`, e.lu.A3)))
```

mat2triplet

*Map Matrix to its Triplet Representation***Description**

From an R object coercible to "[TsparseMatrix](#)", typically a (sparse) matrix, produce its triplet representation which may collapse to a "Duplet" in the case of binary aka pattern, such as "[nMatrix](#)" objects.

**Usage**

```
mat2triplet(x, uniqT = FALSE)
```

**Arguments**

**x** any R object for which `as(x, "TsparseMatrix")` works; typically a [matrix](#) of one of the **Matrix** package matrices.

**uniqT** [logical](#) indicating if the triplet representation should be 'unique' in the sense of [asUniqueT](#)(byrow=FALSE).

**Value**

A [list](#), typically with three components,

**i** vector of row indices for all non-zero entries of x

**j** vector of columns indices for all non-zero entries of x

**x** vector of all non-zero entries of x; exists **only** when `as(x, "TsparseMatrix")` is **not** a "[nsparseMatrix](#)".

Note that the [order](#) of the entries is determined by the coercion to "[TsparseMatrix](#)" and hence typically with increasing j (and increasing i within ties of j).

**Note**

The `mat2triplet()` utility was created to be a more efficient and more predictable substitute for `summary(<sparseMatrix>)`. UseRs have wrongly expected the latter to return a data frame with columns i and j which however is wrong for a "[diagonalMatrix](#)".

**See Also**

The `summary()` method for "[sparseMatrix](#)", [summary,sparseMatrix-method](#).

`mat2triplet()` is conceptually the *inverse* function of [spMatrix](#) and (one case of) [sparseMatrix](#).

**Examples**

```
mat2triplet # simple definition

i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(Ax <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"
str(trA <- mat2triplet(Ax))
stopifnot(i == sort(trA$i), sort(j) == trA$j, x == sort(trA$x))
```

```
D <- Diagonal(x=4:2)
summary(D)
str(mat2triplet(D))
```

matmult-methods

*Matrix (Cross) Products (of Transpose)*

## Description

The basic matrix product, `%%` is implemented for all our `Matrix` and also for `sparseVector` classes, fully analogously to R's base matrix and vector objects.

The functions `crossprod` and `tcrossprod` are matrix products or “cross products”, ideally implemented efficiently without computing `t(.)`'s unnecessarily. They also return `symmetricMatrix` classed matrices when easily detectable, e.g., in `crossprod(m)`, the one argument case.

`tcrossprod()` takes the cross-product of the transpose of a matrix. `tcrossprod(x)` is formally equivalent to, but faster than, the call `x %*% t(x)`, and so is `tcrossprod(x, y)` instead of `x %*% t(y)`.

*Boolean* matrix products are computed via either `%%` or `boolArith = TRUE`.

## Usage

```
S4 method for signature 'CsparseMatrix,diagonalMatrix'
x %*% y

S4 method for signature 'CsparseMatrix,diagonalMatrix'
crossprod(x, y = NULL, boolArith = NA, ...)
.... and for many more signatures

S4 method for signature 'TsparseMatrix,missing'
tcrossprod(x, y = NULL, boolArith = NA, ...)
.... and for many more signatures
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a matrix-like object                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>y</code>         | a matrix-like object, or for <code>[t]crossprod()</code> <code>NULL</code> (by default); the latter case is formally equivalent to <code>y = x</code> .                                                                                                                                                                                                                                                                                                                                            |
| <code>boolArith</code> | <code>logical</code> , i.e., <code>NA</code> , <code>TRUE</code> , or <code>FALSE</code> . If true the result is (coerced to) a pattern matrix, i.e., <code>"nMatrix"</code> , unless there are <code>NA</code> entries and the result will be a <code>"lMatrix"</code> . If false the result is (coerced to) numeric. When <code>NA</code> , currently the default, the result is a pattern matrix when <code>x</code> and <code>y</code> are <code>"nsparseMatrix"</code> and numeric otherwise. |
| <code>...</code>       | potentially more arguments passed to and from methods.                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Details

For some classes in the `Matrix` package, such as `dgCMatrix`, it is much faster to calculate the cross-product of the transpose directly instead of calculating the transpose first and then its cross-product.

`boolArith = TRUE` for regular (“non cross”) matrix products, `%%` cannot be specified. Instead, we provide the `%%` operator for *boolean* matrix products.

**Value**

A [Matrix](#) object, in the one argument case of an appropriate *symmetric* matrix class, i.e., inheriting from [symmetricMatrix](#).

**Methods**

`%*%` signature(`x = "dgeMatrix"`, `y = "dgeMatrix"`): Matrix multiplication; ditto for several other signature combinations, see `showMethods("%*%", class = "dgeMatrix")`.

`%*%` signature(`x = "dtrMatrix"`, `y = "matrix"`) and other signatures (use `showMethods("%*%", class = "dtrMatrix")`): matrix multiplication. Multiplication of (matching) triangular matrices now should remain triangular (in the sense of class [triangularMatrix](#)).

**crossprod** signature(`x = "dgeMatrix"`, `y = "dgeMatrix"`): ditto for several other signatures, use `showMethods("crossprod", class = "dgeMatrix")`, matrix crossproduct, an efficient version of `t(x) %*% y`.

**crossprod** signature(`x = "CsparseMatrix"`, `y = "missing"`) returns `t(x) %*% x` as an `dsCMatrix` object.

**crossprod** signature(`x = "TsparseMatrix"`, `y = "missing"`) returns `t(x) %*% x` as an `dsCMatrix` object.

**crossprod, tcrossprod** signature(`x = "dtrMatrix"`, `y = "matrix"`) and other signatures, see `"%*%"` above.

**Note**

`boolArith = TRUE, FALSE` or `NA` has been newly introduced for **Matrix** 1.2.0 (March 2015). Its implementation has still not been tested extensively. Notably the behaviour for sparse matrices with `x` slots containing extra zeros had not been documented previously, see the `%&%` help page.

Currently, `boolArith = TRUE` is implemented via [CsparseMatrix](#) coercions which may be quite inefficient for dense matrices. Contributions for efficiency improvements are welcome.

**See Also**

[tcrossprod](#) in R's base, and [crossprod](#) and `%*%`. **Matrix** package `%&%` for boolean matrix product methods.

**Examples**

```
A random sparse "incidence" matrix :
m <- matrix(0, 400, 500)
set.seed(12)
m[runif(314, 0, length(m))] <- 1
mm <- as(m, "CsparseMatrix")
object.size(m) / object.size(mm) # smaller by a factor of > 200

tcrossprod() is very fast:
system.time(tCmm <- tcrossprod(mm))# 0 (PIII, 933 MHz)
system.time(cm <- crossprod(t(m))) # 0.16
system.time(cm. <- tcrossprod(m)) # 0.02

stopifnot(cm == as(tCmm, "matrix"))

show sparse sub matrix
tCmm[1:16, 1:30]
```

## Matrix

## Construct a Classed Matrix

**Description**

Construct a Matrix of a class that inherits from Matrix.

**Usage**

```
Matrix(data=NA, nrow=1, ncol=1, byrow=FALSE, dimnames=NULL,
 sparse = NULL, doDiag = TRUE, forceCheck = FALSE)
```

**Arguments**

|            |                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data       | an optional numeric data vector or matrix.                                                                                                                                                                                                                                                                                                                                                            |
| nrow       | when data is not a matrix, the desired number of rows                                                                                                                                                                                                                                                                                                                                                 |
| ncol       | when data is not a matrix, the desired number of columns                                                                                                                                                                                                                                                                                                                                              |
| byrow      | logical. If FALSE (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.                                                                                                                                                                                                                                                                                              |
| dimnames   | a <a href="#">dimnames</a> attribute for the matrix: a list of two character components. They are set if not <a href="#">NULL</a> (as per default).                                                                                                                                                                                                                                                   |
| sparse     | logical or NULL, specifying if the result should be sparse or not. By default, it is made sparse when more than half of the entries are 0.                                                                                                                                                                                                                                                            |
| doDiag     | logical indicating if a <a href="#">diagonalMatrix</a> object should be returned when the resulting matrix is diagonal ( <i>mathematically</i> ). As class <a href="#">diagonalMatrix</a> extends <a href="#">sparseMatrix</a> , this is a natural default for all values of sparse. Otherwise, if doDiag is false, a dense or sparse (depending on sparse) <i>symmetric</i> matrix will be returned. |
| forceCheck | logical indicating if the checks for structure should even happen when data is already a "Matrix" object.                                                                                                                                                                                                                                                                                             |

**Details**

If either of nrow or ncol is not given, an attempt is made to infer it from the length of data and the other parameter. Further, Matrix() makes efforts to keep [logical](#) matrices logical, i.e., inheriting from class [lMatrix](#), and to determine specially structured matrices such as symmetric, triangular or diagonal ones. Note that a *symmetric* matrix also needs symmetric [dimnames](#), e.g., by specifying dimnames = list(NULL, NULL), see the examples.

Most of the time, the function works via a traditional (*full*) [matrix](#). However, Matrix(0, nrow, ncol) directly constructs an "empty" [sparseMatrix](#), as does Matrix(FALSE, \*).

Although it is sometime possible to mix unclassed matrices (created with matrix) with ones of class "Matrix", it is much safer to always use carefully constructed ones of class "Matrix".

**Value**

Returns matrix of a class that inherits from "Matrix". Only if data is not a [matrix](#) and does not already inherit from class [Matrix](#) are the arguments nrow, ncol and byrow made use of.

**See Also**

The classes [Matrix](#), [symmetricMatrix](#), [triangularMatrix](#), and [diagonalMatrix](#); further, [matrix](#).

Special matrices can be constructed, e.g., via [sparseMatrix](#) (sparse), [bdiag](#) (block-diagonal), [bandSparse](#) (banded sparse), or [Diagonal](#).

**Examples**

```
Matrix(0, 3, 2) # 3 by 2 matrix of zeros -> sparse
Matrix(0, 3, 2, sparse=FALSE)# -> 'dense'

4 cases - 3 different results :
Matrix(0, 2, 2) # diagonal !
Matrix(0, 2, 2, sparse=FALSE)# (ditto)
Matrix(0, 2, 2, doDiag=FALSE)# -> sparse symm. "dsCMatrix"
Matrix(0, 2, 2, sparse=FALSE, doDiag=FALSE)# -> dense symm. "dsyMatrix"

Matrix(1:6, 3, 2) # a 3 by 2 matrix (+ integer warning)
Matrix(1:6 + 1, nrow=3)

logical ones:
Matrix(diag(4) > 0) # -> "ldiMatrix" with diag = "U"
Matrix(diag(4) > 0, sparse=TRUE) # (ditto)
Matrix(diag(4) >= 0) # -> "lsyMatrix" (of all 'TRUE')
triangular
l3 <- upper.tri(matrix(,3,3))
(M <- Matrix(l3)) # -> "ltCMatrix"
Matrix(! l3) # -> "ltrMatrix"
as(l3, "CsparseMatrix")# "lgCMatrix"

Matrix(1:9, nrow=3,
 dimnames = list(c("a", "b", "c"), c("A", "B", "C")))
(I3 <- Matrix(diag(3)))# identity, i.e., unit "diagonalMatrix"
str(I3) # note 'diag = "U"' and the empty 'x' slot

(A <- cbind(a=c(2,1), b=1:2))# symmetric *apart* from dimnames
Matrix(A) # hence 'dgeMatrix'
(As <- Matrix(A, dimnames = list(NULL,NULL)))# -> symmetric
forceSymmetric(A) # also symmetric, w/ symm. dimnames
stopifnot(is(As, "symmetricMatrix"),
 is(Matrix(0, 3,3), "sparseMatrix"),
 is(Matrix(FALSE, 1,1), "sparseMatrix"))
```

---

Matrix-class

---

*Virtual Class "Matrix" of Matrices*

---

**Description**

The **Matrix** class is a class contained by all actual classes in the **Matrix** package. It is a “virtual” class.

## Slots

**Dim** an integer vector of length 2 giving the dimensions of the matrix.

**Dimnames** a list of length 2. Each element must be NULL or a character vector of length equal to the corresponding element of **Dim**.

## Methods

**determinant** signature(x = "Matrix", logarithm = "missing"): and

**determinant** signature(x = "Matrix", logarithm = "logical"): compute the (log) determinant of x. The method chosen depends on the actual Matrix class of x. Note that **det** also works for all our matrices, calling the appropriate determinant() method. The Matrix::det is an exact copy of base::det, but in the correct namespace, and hence calling the S4-aware version of determinant().

**diff** signature(x = "Matrix"): As **diff()** for traditional matrices, i.e., applying **diff()** to each column.

**dim** signature(x = "Matrix"): extract matrix dimensions **dim**.

**dim<-** signature(x = "Matrix", value = "ANY"): where value is integer of length 2. Allows to *reshape* Matrix objects, but only when **prod(value) == prod(dim(x))**.

**dimnames** signature(x = "Matrix"): extract **dimnames**.

**dimnames<-** signature(x = "Matrix", value = "list"): set the dimnames to a **list** of length 2, see **dimnames<-**.

**length** signature(x = "Matrix"): simply defined as **prod(dim(x))** (and hence of mode "double").

**show** signature(object = "Matrix"): **show** method for **printing**. For printing *sparse* matrices, see **printSpMatrix**.

**zapsmall** signature(x = "Matrix"): typically used for "**dMatrix**": **round()** matrix entries such that (relatively) very small entries become zero exactly.

**image** signature(object = "Matrix"): draws an **image** of the matrix entries, using **levelplot()** from package **lattice**.

**head** signature(object = "Matrix"): return only the "*head*", i.e., the first few rows.

**tail** signature(object = "Matrix"): return only the "*tail*", i.e., the last few rows of the respective matrix.

**as.matrix**, **as.array** signature(x = "Matrix"): the same as **as(x, "matrix")**; see also the note below.

**as.vector** signature(x = "Matrix", mode = "missing"): **as.vector(m)** should be identical to **as.vector(as(m, "matrix"))**, implemented more efficiently for some subclasses.

**as(x, "vector")**, **as(x, "numeric")** etc, similarly.

**coerce** signature(from = "ANY", to = "Matrix"): This relies on a correct **as.matrix()** method for from.

There are many more methods that (conceptually should) work for all "Matrix" objects, e.g., **colSums**, **rowMeans**. Even **base** functions may work automatically (if they first call **as.matrix()** on their principal argument), e.g., **apply**, **eigen**, **svd** or **kappa** all do work via coercion to a "traditional" (dense) **matrix**.

**Note**

Loading the Matrix namespace “overloads” `as.matrix` and `as.array` in the **base** namespace by the equivalent of `function(x) as(x, "matrix")`. Consequently, `as.matrix(m)` or `as.array(m)` will properly work when `m` inherits from the “Matrix” class — *also* for functions in package **base** and other packages. E.g., `apply` or `outer` can therefore be applied to “Matrix” matrices.

the classes `dgeMatrix`, `dgCMatrix`, and function `Matrix` for construction (and examples).  
Methods, e.g., for `kronecker`.

**Examples**

```
slotNames("Matrix")

cl <- getClass("Matrix")
names(cl@subclasses) # more than 40 ..

showClass("Matrix")#> output with slots and all subclasses

(M <- Matrix(c(0,1,0,0), 6, 4))
dim(M)
diag(M)
cm <- M[1:4,] + 10*Diagonal(4)
diff(M)
can reshape it even :
dim(M) <- c(2, 12)
M
stopifnot(identical(M, Matrix(c(0,1,0,0), 2,12)),
 all.equal(det(cm),
 determinant(as(cm,"matrix"), log=FALSE)$modulus,
 check.attributes=FALSE))
```

**Description**

`iMatrix` is the virtual class of all integer (S4) matrices. It extends the `Matrix` class directly.

`zMatrix` is the virtual class of all `complex` (S4) matrices. It extends the `Matrix` class directly.

**Examples**

```
showClass("iMatrix")
showClass("zMatrix")
```

---

MatrixClass*The Matrix (Super-) Class of a Class*

---

### Description

Return the (maybe super-)class of class `cl` from package **Matrix**, returning `character(0)` if there is none.

### Usage

```
MatrixClass(cl, cld = getClassDef(cl), ...Matrix = TRUE,
 dropVirtual = TRUE, ...)
```

### Arguments

|                          |                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cl</code>          | string, class name                                                                                                                            |
| <code>cld</code>         | its class definition                                                                                                                          |
| <code>...Matrix</code>   | <code>logical</code> indicating if the result must be of pattern "[dlniz]..Matrix" where the first letter "[dlniz]" denotes the content kind. |
| <code>dropVirtual</code> | <code>logical</code> indicating if virtual classes are included or not.                                                                       |
| <code>...</code>         | further arguments are passed to <code>.selectSuperClasses()</code> .                                                                          |

### Value

a `character` string

### Author(s)

Martin Maechler, 24 Mar 2009

MatrixFactorization-class

*Virtual Class "MatrixFactorization" of Matrix Factorizations*

---

## Description

MatrixFactorization is the virtual class of factorizations of  $m \times n$  matrices  $A$ , having the general form

$$P_1 A P_2 = A_1 \cdots A_p$$

or (equivalently)

$$A = P_1' A_1 \cdots A_p P_2'$$

where  $P_1$  and  $P_2$  are permutation matrices. Factorizations requiring symmetric  $A$  have the constraint  $P_2 = P_1'$ , and factorizations without row or column pivoting have the constraints  $P_1 = I_m$  and  $P_2 = I_n$ , where  $I_m$  and  $I_n$  are the  $m \times m$  and  $n \times n$  identity matrices.

CholeskyFactorization, BunchKaufmanFactorization, SchurFactorization, LU, and QR are the virtual subclasses of MatrixFactorization containing all Cholesky, Bunch-Kaufman, Schur, LU, and QR factorizations, respectively.

## Slots

**Dim** an integer vector of length 2 giving the dimensions of the factorized matrix.

**Dimnames** a list of length 2 preserving the dimnames of the factorized matrix. Each element must be NULL or a character vector of length equal to the corresponding element of Dim.

## Methods

**determinant** signature( $x = \text{"MatrixFactorization"}$ ,  $\text{logarithm} = \text{"missing"}$ ): sets  $\text{logarithm} = \text{TRUE}$  and recalls the generic function.

**dim** signature( $x = \text{"MatrixFactorization"}$ ): returns  $x@Dim$ .

**dimnames** signature( $x = \text{"MatrixFactorization"}$ ): returns  $x@Dimnames$ .

**dimnames<-** signature( $x = \text{"MatrixFactorization"}$ ,  $\text{value} = \text{"NULL"}$ ): returns  $x$  with  $x@Dimnames$  set to  $\text{list}(\text{NULL}, \text{NULL})$ .

**dimnames<-** signature( $x = \text{"MatrixFactorization"}$ ,  $\text{value} = \text{"list"}$ ): returns  $x$  with  $x@Dimnames$  set to  $\text{value}$ .

**length** signature( $x = \text{"MatrixFactorization"}$ ): returns  $\text{prod}(x@Dim)$ .

**show** signature( $\text{object} = \text{"MatrixFactorization"}$ ): prints the internal representation of the factorization using `str`.

**solve** signature( $a = \text{"MatrixFactorization"}$ ,  $b = .$ ): see [solve-methods](#).

**unname** signature( $\text{obj} = \text{"MatrixFactorization"}$ ): returns  $\text{obj}$  with  $\text{obj@Dimnames}$  set to  $\text{list}(\text{NULL}, \text{NULL})$ .

|                    |                                                               |
|--------------------|---------------------------------------------------------------|
| ndenseMatrix-class | <i>Virtual Class "ndenseMatrix" of Dense Logical Matrices</i> |
|--------------------|---------------------------------------------------------------|

---

**Description**

ndenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both [denseMatrix](#) and [lMatrix](#) directly.

**Slots**

**x**: logical vector containing the entries of the matrix.  
**Dim, Dimnames**: see [Matrix](#).

**Extends**

Class "nMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "nMatrix".  
 Class "Matrix", by class "denseMatrix".

**Methods**

```
%*% signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...
%*% signature(x = "ndenseMatrix", y = "nsparseMatrix"): ...
crossprod signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...
crossprod signature(x = "ndenseMatrix", y = "nsparseMatrix"): ...
as.vector signature(x = "ndenseMatrix", mode = "missing"): ...
diag signature(x = "ndenseMatrix"): extracts the diagonal as for all matrices, see the generic
diag().
which signature(x = "ndenseMatrix"), semantically equivalent to base function which(x,
arr.ind); for details, see the lMatrix class documentation.
```

**See Also**

Class [ngeMatrix](#) and the other subclasses.

## Examples

```
showClass("ndenseMatrix")

as(diag(3) > 0, "ndenseMatrix")# -> "nge"
```

---

|        |                                         |
|--------|-----------------------------------------|
| nearPD | <i>Nearest Positive Definite Matrix</i> |
|--------|-----------------------------------------|

---

## Description

Compute the nearest positive definite matrix to an approximate one, typically a correlation or variance-covariance matrix.

## Usage

```
nearPD(x, corr = FALSE, keepDiag = FALSE, base.matrix = FALSE,
 do2eigen = TRUE, doSym = FALSE,
 doDykstra = TRUE, only.values = FALSE,
 ensureSymmetry = !isSymmetric(x),
 eig.tol = 1e-06, conv.tol = 1e-07, posd.tol = 1e-08,
 maxit = 100, conv.norm.type = "I", trace = FALSE)
```

## Arguments

|                |                                                                                                                                                                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x              | numeric $n \times n$ approximately positive definite matrix, typically an approximation to a correlation or covariance matrix. If x is not symmetric (and ensureSymmetry is not false), <code>symmpart(x)</code> is used.                                                          |
| corr           | logical indicating if the matrix should be a <i>correlation</i> matrix.                                                                                                                                                                                                            |
| keepDiag       | logical, generalizing corr: if TRUE, the resulting matrix should have the same diagonal ( <code>diag(x)</code> ) as the input matrix.                                                                                                                                              |
| base.matrix    | logical indicating if the resulting mat component should be a <b>base matrix</b> or (by default) a <b>Matrix</b> of class <code>dpoMatrix</code> .                                                                                                                                 |
| do2eigen       | logical indicating if a <code>posdefify()</code> eigen step should be applied to the result of the Higham algorithm.                                                                                                                                                               |
| doSym          | logical indicating if <code>X &lt;- (X + t(X))/2</code> should be done, after <code>X &lt;- tcrossprod(Qd, Q)</code> ; some doubt if this is necessary.                                                                                                                            |
| doDykstra      | logical indicating if Dykstra's correction should be used; true by default. If false, the algorithm is basically the direct fixpoint iteration $Y_k = P_U(P_S(Y_{k-1}))$ .                                                                                                         |
| only.values    | logical; if TRUE, the result is just the vector of eigenvalues of the approximating matrix.                                                                                                                                                                                        |
| ensureSymmetry | logical; by default, <code>symmpart(x)</code> is used whenever <code>isSymmetric(x)</code> is not true. The user can explicitly set this to TRUE or FALSE, saving the symmetry test. <i>Beware</i> however that setting it FALSE for an asymmetric input x, is typically nonsense! |
| eig.tol        | defines relative positiveness of eigenvalues compared to largest one, $\lambda_1$ . Eigenvalues $\lambda_k$ are treated as if zero when $\lambda_k/\lambda_1 \leq \text{eig.tol}$ .                                                                                                |
| conv.tol       | convergence tolerance for Higham algorithm.                                                                                                                                                                                                                                        |

|                             |                                                                                                                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>posd.tol</code>       | tolerance for enforcing positive definiteness (in the final <code>posdefify</code> step when <code>do2eigen</code> is TRUE).                                                                                    |
| <code>maxit</code>          | maximum number of iterations allowed.                                                                                                                                                                           |
| <code>conv.norm.type</code> | convergence norm type ( <code>norm(*, type)</code> ) used for Higham algorithm. The default is "I" (infinity), for reasons of speed (and back compatibility); using "F" is more in line with Higham's proposal. |
| <code>trace</code>          | logical or integer specifying if convergence monitoring should be traced.                                                                                                                                       |

### Details

This implements the algorithm of Higham (2002), and then (if `do2eigen` is true) forces positive definiteness using code from `posdefify`. The algorithm of Knol and ten Berge (1989) (not implemented here) is more general in that it allows constraints to (1) fix some rows (and columns) of the matrix and (2) force the smallest eigenvalue to have a certain value.

Note that setting `corr = TRUE` just sets `diag(.) <- 1` within the algorithm.

Higham (2002) uses Dykstra's correction, but the version by Jens Oehlschlägel did not use it (accidentally), and still gave reasonable results; this simplification, now only used if `doDykstra = FALSE`, was active in `nearPD()` up to Matrix version 0.999375-40.

### Value

If `only.values = TRUE`, a numeric vector of eigenvalues of the approximating matrix; Otherwise, as by default, an S3 object of class "nearPD", basically a list with components

|                          |                                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>mat</code>         | a matrix of class <code>dpoMatrix</code> , the computed positive-definite matrix.                                   |
| <code>eigenvalues</code> | numeric vector of eigenvalues of <code>mat</code> .                                                                 |
| <code>corr</code>        | logical, just the argument <code>corr</code> .                                                                      |
| <code>normF</code>       | the Frobenius norm ( <code>norm(x-X, "F")</code> ) of the difference between the original and the resulting matrix. |
| <code>iterations</code>  | number of iterations needed.                                                                                        |
| <code>converged</code>   | logical indicating if iterations converged.                                                                         |

### Author(s)

Jens Oehlschlägel donated a first version. Subsequent changes by the Matrix package authors.

A first version of this (with non-optional `corr=TRUE`) has been available as `nearcor()`; and more simple versions with a similar purpose `posdefify()`, both from package `sfsmisc`.

## Examples

```
Higham(2002), p.334f - simple example
A <- matrix(1, 3,3); A[1,3] <- A[3,1] <- 0
n.A <- nearPD(A, corr=TRUE, do2eigen=FALSE)
n.A[c("mat", "normF")]
n.A.m <- nearPD(A, corr=TRUE, do2eigen=FALSE, base.matrix=TRUE)$mat
stopifnot(exprs = {
 all.equal(n.A$mat[1,2], 0.760689917)
 all.equal(n.A$normF, 0.52779033, tolerance=1e-9)
 all.equal(n.A.m, unname(as.matrix(n.A$mat)), tolerance = 1e-15)# seen rel.d.= 1.46e-16
})
set.seed(27)
m <- matrix(round(rnorm(25),2), 5, 5)
m <- m + t(m)
diag(m) <- pmax(0, diag(m)) + 1
(m <- round(cov2cor(m), 2))

str(near.m <- nearPD(m, trace = TRUE))
round(near.m$mat, 2)
norm(m - near.m$mat) # 1.102 / 1.08

if(requireNamespace("sfsmisc")) {
 m2 <- sfsmisc::posdefify(m) # a simpler approach
 norm(m - m2) # 1.185, i.e., slightly "less near"
}

round(nearPD(m, only.values=TRUE), 9)

A longer example, extended from Jens' original,
showing the effects of some of the options:

pr <- Matrix(c(1, 0.477, 0.644, 0.478, 0.651, 0.826,
 0.477, 1, 0.516, 0.233, 0.682, 0.75,
 0.644, 0.516, 1, 0.599, 0.581, 0.742,
 0.478, 0.233, 0.599, 1, 0.741, 0.8,
 0.651, 0.682, 0.581, 0.741, 1, 0.798,
 0.826, 0.75, 0.742, 0.8, 0.798, 1),
 nrow = 6, ncol = 6)

nc. <- nearPD(pr, conv.tol = 1e-7) # default
nc.$iterations # 2
nc.1 <- nearPD(pr, conv.tol = 1e-7, corr = TRUE)
nc.1$iterations # 11 / 12 (!)
ncr <- nearPD(pr, conv.tol = 1e-15)
str(ncr)# still 2 iterations
ncr.1 <- nearPD(pr, conv.tol = 1e-15, corr = TRUE)
ncr.1 $ iterations # 27 / 30 !

ncF <- nearPD(pr, conv.tol = 1e-15, conv.norm = "F")
stopifnot(all.equal(ncr, ncF))# norm type does not matter at all in this example

But indeed, the 'corr = TRUE' constraint did ensure a better solution;
cov2cor() does not just fix it up equivalently :
norm(pr - cov2cor(ncr$mat)) # = 0.09994
norm(pr - ncr.1$mat) # = 0.08746 / 0.08805
```

```

3) a real data example from a 'systemfit' model (3 eq.):
(load(system.file("external", "symW.rda", package="Matrix"))) # "symW"
dim(symW) # 24 x 24
class(symW) # "dsCMatrix": sparse symmetric
if(dev.interactive()) image(symW)
EV <- eigen(symW, only=TRUE)$values
summary(EV) ## looking more closely {EV sorted decreasingly}:
tail(EV) # all 6 are negative
EV2 <- eigen(sWpos <- nearPD(symW)$mat, only=TRUE)$values
stopifnot(EV2 > 0)
if(requireNamespace("sfsmisc")) {
 plot(pmax(1e-3, EV), EV2, type="o", log="xy", xaxt="n", yaxt="n")
 for(side in 1:2) sfsmisc::eaxis(side)
} else
 plot(pmax(1e-3, EV), EV2, type="o", log="xy")
abline(0, 1, col="red3", lty=2)

```

ngeMatrix-class

*Class "ngeMatrix" of General Dense Nonzero-pattern Matrices*

## Description

This is the class of general dense nonzero-pattern matrices, see [nMatrix](#).

## Slots

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim, Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Class "ndenseMatrix", directly. Class "lMatrix", by class "ndenseMatrix". Class "denseMatrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix".

## Methods

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#)); use, e.g., [showMethods\(class="ngeMatrix"\)](#) for details.

## See Also

Non-general logical dense matrix classes such as [ntrMatrix](#), or [nsyMatrix](#); *sparse* logical classes such as [ngCMatrix](#).

## Examples

```

showClass("ngeMatrix")
"lgeMatrix" is really more relevant

```

## Description

The nMatrix class is the virtual “mother” class of all *non-zero pattern* (or simply *pattern*) matrices in the **Matrix** package.

## Slots

Common to *all* matrix object in the package:

**Dim:** Object of class “integer” - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a [character](#) vector length equal the corresponding Dim element.

## Methods

**coerce** signature(from = “matrix”, to = “nMatrix”): Note that these coercions (must) coerce [NAs](#) to non-zero, hence conceptually TRUE. This is particularly important when [sparseMatrix](#) objects are coerced to “nMatrix” and hence to [nsparseMatrix](#).

— — —

Additional methods contain group methods, such as

**Ops** signature(e1 = “nMatrix”, e2 = “...”),...

**Arith** signature(e1 = “nMatrix”, e2 = “...”),...

**Compare** signature(e1 = “nMatrix”, e2 = “...”),...

**Logic** signature(e1 = “nMatrix”, e2 = “...”),...

**Summary** signature(x = “nMatrix”, “...”),...

## See Also

The classes [lMatrix](#), [nsparseMatrix](#), and the mother class, [Matrix](#).

## Examples

```
getClass("nMatrix")
```

```
L3 <- Matrix(upper.tri(diag(3)))
```

```
L3 # an "ltCMatrix"
```

```
as(L3, "nMatrix") # -> ntc*
```

```
similar, not using Matrix()
```

```
as(upper.tri(diag(3)), "nMatrix")# currently "ngTMatrix"
```

**Description**

Returns the number of non-zero values of a numeric-like R object, and in particular an object `x` inheriting from class `Matrix`.

**Usage**

```
nnzero(x, na.counted = NA)
```

**Arguments**

`x` an R object, typically inheriting from class `Matrix` or `numeric`.

`na.counted` a `logical` describing how `NA`s should be counted. There are three possible settings for `na.counted`:

**TRUE** `NA`s are counted as non-zero (since “they are not zero”).

**NA** (default) the result will be `NA` if there are `NA`’s in `x` (since “`NA`’s are not known, i.e., *may be* zero”).

**FALSE** `NA`s are *omitted* from `x` before the non-zero entries are counted.

For sparse matrices, you may often want to use `na.counted = TRUE`.

**Value**

the number of non zero entries in `x` (typically `integer`).

Note that for a *symmetric* sparse matrix `S` (i.e., inheriting from class `symmetricMatrix`), `nnzero(S)` is typically *twice* the `length(S@x)`.

**Methods**

`signature(x = "ANY")` the default method for non-`Matrix` class objects, simply counts the number of 0s in `x`, counting `NA`’s depending on the `na.counted` argument, see above.

`signature(x = "denseMatrix")` conceptually the same as for traditional `matrix` objects, care has to be taken for “`symmetricMatrix`” objects.

`signature(x = "diagonalMatrix")`, **and** `signature(x = "indMatrix")` fast simple methods for these special “`sparseMatrix`” classes.

`signature(x = "sparseMatrix")` typically, the most interesting method, also carefully taking “`symmetricMatrix`” objects into account.

**See Also**

The `Matrix` class also has a `length` method; typically, `length(M)` is much larger than `nnzero(M)` for a sparse matrix `M`, and the latter is a better indication of the *size* of `M`.

`drop0`, `zapsmall`.

## Examples

```
m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "TsparseMatrix"))
nnzero(mT)
(S <- crossprod(mT))
nnzero(S)
str(S) # slots are smaller than nnzero()
stopifnot(nnzero(S) == sum(as.matrix(S) != 0))# failed earlier

data(KNex, package = "Matrix")
M <- KNex$mm
class(M)
dim(M)
length(M); stopifnot(length(M) == prod(dim(M)))
nnzero(M) # more relevant than length
the above are also visible from
str(M)
```

---

norm-methods

---

*Matrix Norms*

---

## Description

Computes a matrix norm of *x*, using Lapack for dense matrices. The norm can be the one ("0", or "1") norm, the infinity ("I") norm, the Frobenius ("F") norm, the maximum modulus ("M") among elements of a matrix, or the spectral norm or 2-norm ("2"), as determined by the value of *type*.

## Usage

```
norm(x, type, ...)
```

## Arguments

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>x</i>    | a real or complex matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>type</i> | A character indicating the type of norm desired.<br>"0", "o" or "1" specifies the one norm, (maximum absolute column sum);<br>"I" or "i" specifies the infinity norm (maximum absolute row sum);<br>"F" or "f" specifies the Frobenius norm (the Euclidean norm of <i>x</i> treated as if it were a vector);<br>"M" or "m" specifies the maximum modulus of all the elements in <i>x</i> ; and<br>"2" specifies the "spectral norm" aka "2-norm", which is the largest singular value ( <a href="#">svd</a> ) of <i>x</i> .<br>The default is "0". Only the first character of <i>type</i> [1] is used. |
| ...         | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Details

For dense matrices, the methods eventually call the Lapack functions `dlange`, `dlansy`, `dlantr`, `zlange`, `zlansy`, and `zlantr`.

**Value**

A numeric value of class "norm", representing the quantity chosen according to type.

norm(x)# = "0" = "1"
stopifnot(identical(norm(x), norm(x, "1")))
norm(x, "I")# the same, because 'x' is symmetric

allnorms <- function(x) {
 ## norm(NA, "2") did not work until R 4.0.0
 do2 <- getRversion() >= "4.0.0" || !anyNA(x)
 vapply(c("1", "I", "F", "M", if(do2) "2"), norm, 0, x = x)
}
allnorms(x)
allnorms(Hilbert(10))

i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
A <- sparseMatrix(i, j, x = x) ## 8 x 10 "dgCMatrix"
(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"
(tA <- sparseMatrix(i, j, x = x, triangular= TRUE)) ## 10 x 10 "dtCMatrix"
(allnorms(A) -> nA)
allnorms(sA)
allnorms(tA)
stopifnot(all.equal(nA, allnorms(as(A, "matrix"))),
 all.equal(nA, allnorms(tA))) # because tA == rbind(A, 0, 0)
A. <- A; A.[1,3] <- NA
stopifnot(is.na(allnorms(A.))) # gave error
```

---

nsparseMatrix-class     *Sparse "pattern" Matrices*

---

**Description**

The nsparseMatrix class is a virtual class of sparse “*pattern*” matrices, i.e., binary matrices conceptually with TRUE/FALSE entries. Only the positions of the elements that are TRUE are stored.

These can be stored in the “triplet” form ([TsparseMatrix](#), subclasses ngTMatrix, nsTMatrix, and ntTMatrix which really contain pairs, not triplets) or in compressed column-oriented form (class [CsparseMatrix](#), subclasses ngCMatrix, nsCMatrix, and ntCMatrix) or—*rarely*—in compressed row-oriented form (class [RsparseMatrix](#), subclasses ngrMatrix, nsRMatrix, and ntrMatrix). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

## Objects from the Class

Objects can be created by calls of the form `new("ngCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the pattern form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence numeric sparse matrices can be treated as sparse pattern matrices.

## Slots

- uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when diag is "U". Present in the triangular classes only.
- p**: Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- i**: Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- j**: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed row-oriented forms only.
- Dim**: Object of class "integer" - the dimensions of the matrix.

## Methods

**coerce** signature(`from = "dgCMatrix"`, `to = "ngCMatrix"`), and many similar ones; typically you should coerce to "nsparseMatrix" (or "nMatrix"). Note that coercion to a sparse pattern matrix records all the potential non-zero entries, i.e., explicit ("non-structural") zeroes are coerced to TRUE, not FALSE, see the example.

**t** signature(`x = "ngCMatrix"`): returns the transpose of `x`

**which** signature(`x = "lsparseMatrix"`), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the [lMatrix](#) class documentation.

## See Also

the class [dgCMatrix](#)

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
``extract the nonzero-pattern of (m) into an nMatrix``:
nm <- as(m, "nsparseMatrix") ## -> will be a "ngCMatrix"
str(nm) # no 'x' slot
nnm <- !nm # no longer sparse
consistency check:
stopifnot(xor(as(nm, "matrix"),
 as(nnm, "matrix")))
```

```
low-level way of adding "non-structural zeros" :
nnm <- as(nnm, "lsparseMatrix") # "lgCMatrix"
nnm@x[2:4] <- c(FALSE, NA, NA)
nnm
as(nnm, "nMatrix") # NAs *and* non-structural 0 |---> 'TRUE'

data(KNex, package = "Matrix")
nmm <- as(KNex $ mm, "nMatrix")
str(xlx <- crossprod(nmm))# "nsCMatrix"
stopifnot(isSymmetric(xlx))
image(xlx, main=paste("crossprod(nmm) : Sparse", class(xlx)))
```

---

nsyMatrix-class

*Symmetric Dense Nonzero-Pattern Matrices*

---

## Description

The "nsyMatrix" class is the class of symmetric, dense nonzero-pattern matrices in non-packed storage and "nspMatrix" is the class of these in packed storage. Only the upper triangle or the lower triangle is stored.

## Objects from the Class

Objects can be created by calls of the form `new("nsyMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

"nsyMatrix" extends class "ngeMatrix", directly, whereas

"nspMatrix" extends class "ndenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, *indirectly*, use [showClass\("nsyMatrix"\)](#), e.g., for details.

## Methods

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#); use, e.g., [showMethods\(class="nsyMatrix"\)](#) for details.

## See Also

[ngeMatrix](#), [Matrix](#), [t](#)

## Examples

```
(s0 <- new("nsyMatrix"))

(M2 <- Matrix(c(TRUE, NA, FALSE, FALSE), 2, 2)) # logical dense (ltr)
(sM <- M2 & t(M2)) # -> "lge"
class(sM <- as(sM, "nMatrix")) # -> "nge"
 (sM <- as(sM, "symmetricMatrix")) # -> "nsy"
str(sM <- as(sM, "packedMatrix")) # -> "nsp", i.e., packed symmetric
```

---

ntrMatrix-class

Triangular Dense Logical Matrices

---

## Description

The "ntrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ntpMatrix" class is the same except in packed storage.

## Slots

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

"ntrMatrix" extends class "ngeMatrix", directly, whereas  
 "ntpMatrix" extends class "ndenseMatrix", directly.

Both extend Class "triangularMatrix", directly, and class "denseMatrix", "lMatrix" and others, indirectly, use [showClass\("nsyMatrix"\)](#), e.g., for details.

## Methods

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#); use, e.g., [showMethods\(class="ntrMatrix"\)](#) for details.

## See Also

Classes [ngeMatrix](#), [Matrix](#); function [t](#)

## Examples

```
showClass("ntrMatrix")

str(new("ntpMatrix"))
(nutr <- as(upper.tri(matrix(, 4, 4)), "ndenseMatrix"))
str(nutp <- pack(nutr)) # packed matrix: only 10 = 4*(4+1)/2 entries
!nutp # the logical negation (is *not* logical triangular !)
but this one is:
stopifnot(all.equal(nutp, pack(!!nutp)))
```

---

pack-methods

Representation of Packed and Unpacked Dense Matrices

---

## Description

`pack()` coerces dense symmetric and dense triangular matrices from unpacked format (storing the full matrix) to packed format (storing only one of the upper and lower triangles). `unpack()` performs the reverse coercion. The two formats are formalized by the virtual classes "[packedMatrix](#)" and "[unpackedMatrix](#)".

## Usage

```
pack(x, ...)
S4 method for signature 'dgeMatrix'
pack(x, symmetric = NA, upperTri = NA, ...)
S4 method for signature 'lgeMatrix'
pack(x, symmetric = NA, upperTri = NA, ...)
S4 method for signature 'ngeMatrix'
pack(x, symmetric = NA, upperTri = NA, ...)
S4 method for signature 'matrix'
pack(x, symmetric = NA, upperTri = NA, ...)

unpack(x, ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                            |

| ...       | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                         |

## Details

`pack(x)` checks matrices  $x$  *not* inheriting from one of the virtual classes "`symmetricMatrix`" "`triangularMatrix`" for symmetry (via `isSymmetric()`) then for upper and lower triangularity (via `isTriangular()`) in order to identify a suitable coercion. Setting one or both of `symmetric` and `upperTri` to `TRUE` or `FALSE` rather than `NA` allows skipping of irrelevant tests for large matrices known to be symmetric or (upper or lower) triangular.

Users should *not* assume that `pack()` and `unpack()` are inverse operations. Specifically, `y <- unpack(pack(x))` may not reproduce an "unpackedMatrix"  $x$  in the sense of `identical()`. See the examples.

## Value

**For `pack()`:** a "packedMatrix" giving the condensed representation of  $x$ .

**For `unpack()`:** an "unpackedMatrix" giving the full storage representation of  $x$ .

## Examples

```
showMethods("pack")
(s <- crossprod(matrix(sample(15), 5,3))) # traditional symmetric matrix
(sp <- pack(s))
mt <- as.matrix(tt <- tril(s))
(pt <- pack(mt))
stopifnot(identical(pt, pack(tt)),
 dim(s) == dim(sp), all(s == sp),
 dim(mt) == dim(pt), all(mt == pt), all(mt == tt))

showMethods("unpack")
(cp4 <- chol(Hilbert(4))) # is triangular
tp4 <- pack(cp4) # [t]riangular [p]acked
str(tp4)
(unpack(tp4))
stopifnot(identical(tp4, pack(unpack(tp4))))

z1 <- new("dsyMatrix", Dim = c(2L, 2L), x = as.double(1:4), uplo = "U")
z2 <- unpack(pack(z1))
stopifnot(!identical(z1, z2), # _not_ identical
 all(z1 == z2)) # but mathematically equal
cbind(z1@x, z2@x) # (unused!) lower triangle is "lost" in translation
```

|--------------------|-------------------------------------------------------|
| packedMatrix-class | Virtual Class "packedMatrix" of Packed Dense Matrices |
|--------------------|-------------------------------------------------------|

---

## Description

Class "packedMatrix" is the *virtual* class of dense symmetric or triangular matrices in "packed" format, storing only the  $\text{choose}(n+1, 2) = n*(n+1)/2$  elements of the upper or lower triangle of an  $n$ -by- $n$  matrix. It is used to define common methods for efficient subsetting, transposing, etc. of its *proper* subclasses: currently "`dlnspMatrix`" (packed symmetric), "`dlntpMatrix`" (packed triangular), and subclasses of these, such as "`dppMatrix`".

**Slots**

uplo: "character"; either "U", for upper triangular, and "L", for lower.

Dim, Dimnames: as all [Matrix](#) objects.

**Extends**

Class "[denseMatrix](#)", directly. Class "[Matrix](#)", by class "[denseMatrix](#)", distance 2.

**Methods**

**pack** signature(x = "packedMatrix"): ...  
**unpack** signature(x = "packedMatrix"): ...  
**isSymmetric** signature(object = "packedMatrix"): ...  
**isTriangular** signature(object = "packedMatrix"): ...  
**isDiagonal** signature(object = "packedMatrix"): ...  
**t** signature(x = "packedMatrix"): ...  
**diag** signature(x = "packedMatrix"): ...  
**diag<-** signature(x = "packedMatrix"): ...

**Author(s)**

Mikael Jagan

[pack](#) and [unpack](#); its virtual "complement" "[unpackedMatrix](#)"; its proper subclasses "[dspMatrix](#)", "[ltpMatrix](#)", etc.

**Examples**

```
showClass("packedMatrix")
showMethods(classes = "packedMatrix")
```

---

pMatrix-class

*Permutation matrices*

---

**Description**

The pMatrix class is the class of *permutation* matrices, stored as 1-based integer permutation vectors. A permutation matrix is a square matrix whose rows *and* columns are all standard unit vectors. It follows that permutation matrices are a special case of *index* matrices (hence pMatrix is defined as a direct subclass of [indMatrix](#)).

Multiplying a matrix on the left by a permutation matrix is equivalent to permuting its rows. Analogously, multiplying a matrix on the right by a permutation matrix is equivalent to permuting its columns. Indeed, such products are implemented in **Matrix** as indexing operations; see ‘Details’ below.

## Details

By definition, a permutation matrix is both a row index matrix and a column index matrix. However, the perm slot of a pMatrix cannot be used interchangeably as a row index vector and column index vector. If margin=1, then perm is a row index vector, and the corresponding column index vector can be computed as `invPerm(perm)`, i.e., by inverting the permutation. Analogously, if margin=2, then perm and `invPerm(perm)` are column and row index vectors, respectively.

Given an n-by-n row permutation matrix P with perm slot p and a matrix M with conformable dimensions, we have

$$\begin{array}{llll}
 PM & = & P \%* \% M & = & M[p, ] \\
 MP & = & M \%* \% P & = & M[, i(p)] \\
 P'M & = & \text{crossprod}(P, M) & = & M[i(p), ] \\
 MP' & = & \text{tcrossprod}(M, P) & = & M[, p] \\
 P'P & = & \text{crossprod}(P) & = & \text{Diagonal}(n) \\
 PP' & = & \text{tcrossprod}(P) & = & \text{Diagonal}(n)
 \end{array}$$

where  $i := \text{invPerm}$ .

## Objects from the Class

Objects can be created explicitly with calls of the form `new("pMatrix", ...)`, but they are more commonly created by coercing 1-based integer index vectors, with calls of the form `as(., "pMatrix")`; see ‘Methods’ below.

## Slots

`margin, perm` inherited from superclass `indMatrix`. Here, perm is an integer vector of length `Dim[1]` and a permutation of `1:Dim[1]`.

`Dim, Dimnames` inherited from virtual superclass `Matrix`.

## Extends

Class `"indMatrix"`, directly.

## Methods

`%* %` signature(`x = "pMatrix"`, `y = "Matrix"`) and others listed by `showMethods("%* %", classes = "pMatrix")`: matrix products implemented where appropriate as indexing operations.

`coerce` signature(`from = "numeric"`, `to = "pMatrix"`): supporting typical pMatrix construction from a vector of positive integers, specifically a permutation of `1:n`. Row permutation is assumed.

`t` signature(`x = "pMatrix"`): the transpose, which is a pMatrix with identical perm but opposite margin. Coincides with the inverse, as permutation matrices are orthogonal.

`solve` signature(`a = "pMatrix"`, `b = "missing"`): the inverse permutation matrix, which is a pMatrix with identical perm but opposite margin. Coincides with the transpose, as permutation matrices are orthogonal. See `showMethods("solve", classes = "pMatrix")` for more signatures.

`determinant` signature(`x = "pMatrix"`, `logarithm = "logical"`): always returning 1 or -1, as permutation matrices are orthogonal. In fact, the result is exactly the *sign* of the permutation.

**See Also**

Superclass [indMatrix](#) of index matrices, for many inherited methods; [invPerm](#), for computing inverse permutation vectors.

**Examples**

```
(pm1 <- as(as.integer(c(2,3,1)), "pMatrix"))
t(pm1) # is the same as
solve(pm1)
pm1 %*% t(pm1) # check that the transpose is the inverse
stopifnot(all(diag(3) == as(pm1 %*% t(pm1), "matrix")),
 is.logical(as(pm1, "matrix")))

set.seed(11)
random permutation matrix :
(p10 <- as(sample(10), "pMatrix"))

Permute rows / columns of a numeric matrix :
(mm <- round(array(rnorm(3 * 3), c(3, 3)), 2))
mm %*% pm1
pm1 %*% mm
try(as(as.integer(c(3,3,1)), "pMatrix"))# Error: not a permutation

as(pm1, "TsparseMatrix")
p10[1:7, 1:4] # gives an "ngTMatrix" (most economic!)

row-indexing of a <pMatrix> keeps it as an <indMatrix>:
p10[1:3,]
```

---

printSpMatrix

---

*Format and Print Sparse Matrices Flexibly*

---

**Description**

Format and print sparse matrices flexibly. These are the “workhorses” used by the [format](#), [show](#) and [print](#) methods for sparse matrices. If *x* is large, `printSpMatrix2(x)` calls `printSpMatrix()` twice, namely, for the first and the last few rows, suppressing those in between, and also suppresses columns when *x* is too wide.

`printSpMatrix()` basically prints the result of `formatSpMatrix()`.

**Usage**

```
formatSpMatrix(x, digits = NULL, maxp = 1e9,
 cld = getClassDef(class(x)), zero.print = ".",
 col.names, note.dropping.colnames = TRUE, uniDiag = TRUE,
 align = c("fancy", "right"), ...)

printSpMatrix(x, digits = NULL, maxp = max(100L, getOption("max.print")),
 cld = getClassDef(class(x)),
 zero.print = ".", col.names, note.dropping.colnames = TRUE,
 uniDiag = TRUE, col.trailer = "",
 align = c("fancy", "right"), ...)
```

```
printSpMatrix2(x, digits = NULL, maxp = max(100L, getOption("max.print")),
 zero.print = ".", col.names, note.dropping.colnames = TRUE,
 uniDiag = TRUE, suppRows = NULL, suppCols = NULL,
 col.trailer = if(suppCols) "....." else "",
 align = c("fancy", "right"),
 width = getOption("width"), fitWidth = TRUE, ...)
```

## Arguments

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                      | an R object inheriting from class <code>sparseMatrix</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>digits</code>                 | significant digits to use for printing, see <code>print.default</code> , the default, <code>NULL</code> , corresponds to using <code>getOption("digits")</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>maxp</code>                   | integer, default from <code>options(max.print)</code> , influences how many entries of large matrices are printed at all. Typically should not be smaller than around 1000; values smaller than 100 are silently “rounded up” to 100.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>cld</code>                    | the class definition of <code>x</code> ; must be equivalent to <code>getClassDef(class(x))</code> and exists mainly for possible speedup.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>zero.print</code>             | character which should be printed for <i>structural</i> zeroes. The default <code>"."</code> may occasionally be replaced by <code>" "</code> (blank); using <code>"0"</code> would look almost like <code>print()</code> ing of non-sparse matrices.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>col.names</code>              | logical or string specifying if and how column names of <code>x</code> should be printed, possibly abbreviated. The default is taken from <code>options("sparse.colnames")</code> if that is set, otherwise <code>FALSE</code> unless there are less than ten columns. When <code>TRUE</code> the full column names are printed.<br>When <code>col.names</code> is a string beginning with <code>"abb"</code> or <code>"sub"</code> and ending with an integer <code>n</code> (i.e., of the form <code>"abb... &lt;n&gt;"</code> ), the column names are <code>abbreviate()</code> d or <code>substring()</code> ed to (target) length <code>n</code> , see the examples. |
| <code>note.dropping.colnames</code> | logical specifying, when <code>col.names</code> is <code>FALSE</code> if the dropping of the column names should be noted, <code>TRUE</code> by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>uniDiag</code>                | logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as <code>"I"</code> instead of <code>"1"</code> (to emphasize that the 1's are “structural”).                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>col.trailer</code>            | a string to be appended to the right of each column; this is typically made use of by <code>show(&lt;sparseMatrix&gt;)</code> only, when suppressing columns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>suppRows, suppCols</code>     | logicals or <code>NULL</code> , for <code>printSpMatrix2()</code> specifying if rows or columns should be suppressed in printing. If <code>NULL</code> , sensible defaults are determined from <code>dim(x)</code> and <code>options(c("width", "max.print"))</code> . Setting both to <code>FALSE</code> may be a very bad idea.                                                                                                                                                                                                                                                                                                                                         |
| <code>align</code>                  | a string specifying how the <code>zero.print</code> codes should be aligned, i.e., padded as strings. The default, <code>"fancy"</code> , takes some effort to align the typical <code>zero.print = "."</code> with the position of 0, i.e., the first decimal (one left of decimal point) of the numbers printed, whereas <code>align = "right"</code> just makes use of <code>print(*, right = TRUE)</code> .                                                                                                                                                                                                                                                           |
| <code>width</code>                  | number, a positive integer, indicating the approximately desired (line) width of the output, see also <code>fitWidth</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>fitWidth</code>               | logical indicating if some effort should be made to match the desired width or temporarily enlarge that if deemed necessary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>...</code>                    | unused optional arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Details

**formatSpMatrix:** If  $x$  is large, only the first rows making up the approximately first `maxp` entries is used, otherwise all of  $x$ . `.formatSparseSimple()` is applied to (a dense version of) the matrix. Then, `formatSparseM` is used, unless in trivial cases or for sparse matrices without `x` slot.

## Value

`formatSpMatrix()`  
 returns a character matrix with possibly empty column names, depending on `col.names` etc, see above.

`printSpMatrix*()`  
 return  $x$  *invisibly*, see `invisible`.

## Author(s)

Martin Maechler

## See Also

the virtual class `sparseMatrix` and the classes extending it; maybe `sparseMatrix` or `spMatrix` as simple constructors of such matrices.

The underlying utilities `formatSparseM` and `.formatSparseSimple()` (on the same page).

## Examples

```
f1 <- gl(5, 3, labels = LETTERS[1:5])
X <- as(f1, "sparseMatrix")
X ## <==> show(X) <==> print(X)
t(X) ## shows column names, since only 5 columns

X2 <- as(gl(12, 3, labels = paste(LETTERS[1:12], "c", sep=".")),
 "sparseMatrix")
X2
less nice, but possible:
print(X2, col.names = TRUE) # use [,1] [,2] .. => does not fit

Possibilities with column names printing:
t(X2) # suppressing column names
print(t(X2), col.names=TRUE)
print(t(X2), zero.print = "", col.names="abbr. 1")
print(t(X2), zero.print = "-", col.names="substring 2")
```

## Description

Computes the pivoted QR factorization of an  $m \times n$  real matrix  $A$ , which has the general form

$$P_1 A P_2 = Q R$$

or (equivalently)

$$A = P_1' Q R P_2'$$

where  $P_1$  and  $P_2$  are permutation matrices,  $Q = \prod_{j=1}^n H_j$  is an  $m \times m$  orthogonal matrix equal to the product of  $n$  Householder matrices  $H_j$ , and  $R$  is an  $m \times n$  upper trapezoidal matrix.

`denseMatrix` use the default method implemented in **base**, namely `qr.default`. It is built on LINPACK routine `dqrdc` and LAPACK routine `dgeqp3`, which do not pivot rows, so that  $P_1$  is an identity matrix.

Methods for `sparseMatrix` are built on CXSparse routines `cs_sqr` and `cs_qr`, which require  $m \geq n$ .

## Usage

```
qr(x, ...)
S4 method for signature 'dgCMatrix'
qr(x, order = 3L, ...)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | a <a href="#">finite</a> matrix or <a href="#">Matrix</a> to be factorized, satisfying <code>nrow(x) &gt;= ncol(x)</code> if sparse.                                                                                                                                                                                                                                                                                   |
| <code>order</code> | an integer in <code>0:3</code> passed to CXSparse routine <code>cs_sqr</code> , indicating a strategy for choosing the column permutation $P_2$ . 0 means no column permutation. 1, 2, and 3 indicate a fill-reducing ordering of $A + A'$ , $\tilde{A}'\tilde{A}$ , and $A'A$ , where $\tilde{A}$ is $A$ with “dense” rows removed. Do not set to 0 unless you know that the column order of $A$ is already sensible. |
| <code>...</code>   | further arguments passed to or from methods.                                                                                                                                                                                                                                                                                                                                                                           |

## Details

If  $x$  is sparse and structurally rank deficient, having structural rank  $r < n$ , then  $x$  is augmented with  $(n - r)$  rows of (partly non-structural) zeros, such that the augmented matrix has structural rank  $n$ . This augmented matrix is factorized as described above:

$$P_1 A P_2 = P_1 \begin{bmatrix} A_0 \\ 0 \end{bmatrix} P_2 = Q R$$

where  $A_0$  denotes the original, user-supplied  $(m - (n - r)) \times n$  matrix.

## Value

An object representing the factorization, inheriting from virtual S4 class `QR` or S3 class `qr`. The specific class is `qr` unless  $x$  inherits from virtual class `sparseMatrix`, in which case it is `sparseQR`.

Generic functions [Cholesky](#), [BunchKaufman](#), [Schur](#), and [lu](#), for computing other factorizations.

**Examples**

```
showMethods("qr", inherited = FALSE)

Rank deficient: columns 3 {b2} and 6 {c3} are "extra"
M <- as(cbind(a1 = 1,
 b1 = rep(c(1, 0), each = 3L),
 b2 = rep(c(0, 1), each = 3L),
 c1 = rep(c(1, 0, 0), 2L),
 c2 = rep(c(0, 1, 0), 2L),
 c3 = rep(c(0, 0, 1), 2L)),
 "CsparseMatrix")
rownames(M) <- paste0("r", seq_len(nrow(M)))
b <- 1:6
eps <- .Machine$double.eps

.... [1] full rank
==> a least squares solution of A x = b exists
and is unique _in exact arithmetic_

(A1 <- M[, -c(3L, 6L)])
(qr.A1 <- qr(A1))

stopifnot(exprs = {
 rankMatrix(A1) == ncol(A1)
 { d1 <- abs(diag(qr.A1@R)); sum(d1 < max(d1) * eps) == 0L }
 rcond(crossprod(A1)) >= eps
 all.equal(qr.coef(qr.A1, b), drop(solve(crossprod(A1), crossprod(A1, b))))
 all.equal(qr.fitted(qr.A1, b) + qr.resid(qr.A1, b), b)
})

.... [2] numerically rank deficient with full structural rank
==> a least squares solution of A x = b does not
exist or is not unique _in exact arithmetic_

(A2 <- M)
(qr.A2 <- qr(A2))

stopifnot(exprs = {
 rankMatrix(A2) == ncol(A2) - 2L
 { d2 <- abs(diag(qr.A2@R)); sum(d2 < max(d2) * eps) == 2L }
 rcond(crossprod(A2)) < eps

 ## 'qr.coef' computes unique least squares solution of "nearby" problem
 ## Z x = b for some full rank Z ~ A, currently without warning {FIXME} !
 tryCatch({ qr.coef(qr.A2, b); TRUE }, condition = function(x) FALSE)
```

```

 all.equal(qr.fitted(qr.A2, b) + qr.resid(qr.A2, b), b)
 })

.... [3] numerically and structurally rank deficient
==> factorization of _augmented_ matrix with
full structural rank proceeds as in [2]

NB: implementation details are subject to change; see (*) below

A3 <- M
A3[, c(3L, 6L)] <- 0
A3
(qr.A3 <- qr(A3)) # with a warning ... "additional 2 row(s) of zeros"

stopifnot(exprs = {
 ## sparseQR object preserves the unaugmented dimensions (*)
 dim(qr.A3) == dim(A3)
 dim(qr.A3@V) == dim(A3) + c(2L, 0L)
 dim(qr.A3@R) == dim(A3) + c(2L, 0L)

 ## The augmented matrix remains numerically rank deficient
 rankMatrix(A3) == ncol(A3) - 2L
 { d3 <- abs(diag(qr.A3@R)); sum(d3 < max(d3) * eps) == 2L }
 rcond(crossprod(A3)) < eps
})

Auxiliary functions accept and return a vector or matrix
with dimensions corresponding to the unaugmented matrix (*),
in all cases with a warning
qr.coef (qr.A3, b)
qr.fitted(qr.A3, b)
qr.resid (qr.A3, b)

.... [4] yet more examples

By disabling column pivoting, one gets the "vanilla" factorization
$A = Q \sim R$, where $Q \sim := P1' Q$ is orthogonal because $P1$ and Q are

(qr.A1.pp <- qr(A1, order = 0L)) # partial pivoting

ae1 <- function(a, b, ...) all.equal(as(a, "matrix"), as(b, "matrix"), ...)
ae2 <- function(a, b, ...) ae1(unname(a), unname(b), ...)

stopifnot(exprs = {
 length(qr.A1 @q) == ncol(A1)
 length(qr.A1.pp@q) == 0L # indicating no column pivoting
 ae2(A1[, qr.A1@q + 1L], qr.Q(qr.A1) %%% qr.R(qr.A1))
 ae2(A1 , qr.Q(qr.A1.pp) %%% qr.R(qr.A1.pp))
})

```

## Description

Compute ‘the’ matrix rank, a well-defined functional in theory(\*), somewhat ambiguous in practice. We provide several methods, the default corresponding to Matlab’s definition.

(\*) The rank of a  $n \times m$  matrix  $A$ ,  $rk(A)$ , is the maximal number of linearly independent columns (or rows); hence  $rk(A) \leq \min(n, m)$ .

## Usage

```
rankMatrix(x, tol = NULL,
 method = c("tolNorm2", "qr.R", "qrLINPACK", "qr",
 "useGrad", "maybeGrad"),
 sval = svd(x, 0, 0)$d, warn.t = TRUE, warn.qr = TRUE)

qr2rankMatrix(qr, tol = NULL, isBqr = is.qr(qr), do.warn = TRUE)
```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | numeric matrix, of dimension $n \times m$ , say.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| tol    | nonnegative number specifying a (relative, “scalefree”) tolerance for testing of “practically zero” with specific meaning depending on method; by default, $\max(\dim(x)) * .Machine\$double.eps$ is according to Matlab’s default (for its only method which is our method=“tolNorm2”).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| method | <p>a character string specifying the computational method for the rank, can be abbreviated:</p> <p>“tolNorm2”: the number of singular values <math>\geq \text{tol} * \max(\text{sval})</math>;</p> <p>“qrLINPACK”: for a dense matrix, this is the rank of <code>qr(x, tol, LAPACK=FALSE)</code> (which is <code>qr(...)\$rank</code>);<br/> This (“qr*”, dense) version used to be <i>the</i> recommended way to compute a matrix rank for a while in the past.<br/> For sparse x, this is equivalent to “qr.R”.</p> <p>“qr.R”: this is the rank of triangular matrix <math>R</math>, where <code>qr()</code> uses LAPACK or a “sparseQR” method (see <a href="#">qr-methods</a>) to compute the decomposition <math>QR</math>. The rank of <math>R</math> is then defined as the number of “non-zero” diagonal entries <math>d_i</math> of <math>R</math>, and “non-zero”’s fulfill <math> d_i  \geq \text{tol} \cdot \max( d_i )</math>.</p> <p>“qr”: is for back compatibility; for dense x, it corresponds to “qrLINPACK”, whereas for sparse x, it uses “qr.R”.</p> <p>For all the “qr*” methods, singular values <code>sval</code> are not used, which may be crucially important for a large sparse matrix x, as in that case, when <code>sval</code> is not specified, the default, computing <code>svd()</code> currently coerces x to a dense matrix.</p> <p>“useGrad”: considering the “gradient” of the (decreasing) singular values, the index of the <i>smallest</i> gap.</p> <p>“maybeGrad”: choosing method “useGrad” only when that seems <i>reasonable</i>; otherwise using “tolNorm2”.</p> |
| sval   | numeric vector of non-increasing singular values of x; typically unspecified and computed from x when needed, i.e., unless method = “qr”.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| warn.t | logical indicating if <code>rankMatrix()</code> should warn when it needs <code>t(x)</code> instead of x. Currently, for method = “qr” only, gives a warning by default because the caller often could have passed <code>t(x)</code> directly, more efficiently.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|         |                                                                                                                                                        |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| warn.qr | in the <i>QR</i> cases (i.e., if method starts with "qr"), rankMatrix() calls qr2rankMatrix(..., do.warn = warn.qr), see below.                        |
| qr      | an R object resulting from <code>qr(x, ...)</code> , i.e., typically inheriting from class "qr" or "sparseQR".                                         |
| isBqr   | logical indicating if qr is resulting from <code>base qr()</code> . (Otherwise, it is typically from <b>Matrix</b> package <code>sparse qr()</code> .) |
| do.warn | logical; if true, warn about non-finite diagonal entries in the <i>R</i> matrix of the <i>QR</i> decomposition. Do not change lightly!                 |

### Details

qr2rankMatrix() is typically called from rankMatrix() for the "qr"\* methods, but can be used directly - much more efficiently in case the qr-decomposition is available anyway.

### Value

If *x* is a matrix of all 0 (or of zero dimension), the rank is zero; otherwise, typically a positive integer in `1:min(dim(x))` with attributes detailing the method used.

There are rare cases where the sparse *QR* decomposition “fails” in so far as the diagonal entries of *R*, the  $d_i$  (see above), end with non-finite, typically `NaN` entries. Then, a warning is signalled (unless `warn.qr / do.warn` is not true) and `NA` (specifically, `NA_integer_`) is returned.

### Note

For large sparse matrices *x*, unless you can specify `sval` yourself, currently `method = "qr"` may be the only feasible one, as the others need `sval` and call `svd()` which currently coerces *x* to a `denseMatrix` which may be very slow or impossible, depending on the matrix dimensions.

Note that in the case of sparse *x*, `method = "qr"`, all non-strictly zero diagonal entries  $d_i$  where counted, up to including **Matrix** version 1.1-0, i.e., that method implicitly used `tol = 0`, see also the `set.seed(42)` example below.

### Author(s)

Martin Maechler; for the "\*Grad" methods building on suggestions by Ravi Varadhan.

### See Also

`qr`, `svd`.

### Examples

```
rankMatrix(cbind(1, 0, 1:3)) # 2

(meths <- eval(formals(rankMatrix)$method))

a "border" case:
H12 <- Hilbert(12)
rankMatrix(H12, tol = 1e-20) # 12; but 11 with default method & tol.
sapply(meths, function(.m.) rankMatrix(H12, method = .m.))
tolNorm2 qr.R qrLINPACK qr useGrad maybeGrad
11 11 12 12 11 11
The meaning of 'tol' for method="qrLINPACK" and *dense* x is not entirely "scale free"
rMQL <- function(ex, M) rankMatrix(M, method="qrLINPACK", tol = 10^-ex)
```

```

rMQR <- function(ex, M) rankMatrix(M, method="qr.R", tol = 10^-ex)
sapply(5:15, rMQL, M = H12) # result is platform dependent
7 7 8 10 10 11 11 11 12 12 12 {x86_64}
sapply(5:15, rMQL, M = 1000 * H12) # not identical unfortunately
7 7 8 10 11 11 12 12 12 12 12
sapply(5:15, rMQR, M = H12)
5 6 7 8 8 9 9 10 10 11 11
sapply(5:15, rMQR, M = 1000 * H12) # the *same*

"sparse" case:
M15 <- kronecker(diag(x=c(100,1,10)), Hilbert(5))
sapply(meths, function(.m.) rankMatrix(M15, method = .m.))
##--> all 15, but 'useGrad' has 14.
sapply(meths, function(.m.) rankMatrix(M15, method = .m., tol = 1e-7)) # all 14

"large" sparse
n <- 250000; p <- 33; nnz <- 10000
L <- sparseMatrix(i = sample.int(n, nnz, replace=TRUE),
 j = sample.int(p, nnz, replace=TRUE),
 x = rnorm(nnz))
(st1 <- system.time(r1 <- rankMatrix(L))) # warning+ ~1.5 sec (2013)
(st2 <- system.time(r2 <- rankMatrix(L, method = "qr"))) # considerably faster!
r1[[1]] == print(r2[[1]]) ## --> (33 TRUE)

another sparse-"qr" one, which ``failed'' till 2013-11-23:
set.seed(42)
f1 <- factor(sample(50, 1000, replace=TRUE))
f2 <- factor(sample(50, 1000, replace=TRUE))
f3 <- factor(sample(50, 1000, replace=TRUE))
D <- t(do.call(rbind, lapply(list(f1,f2,f3), as, 'sparseMatrix'))))
dim(D); nnzero(D) ## 1000 x 150 // 3000 non-zeros (= 2%)
stopifnot(rankMatrix(D, method='qr') == 148,
 rankMatrix(crossprod(D),method='qr') == 148)

zero matrix has rank 0 :
stopifnot(sapply(meths, function(.m.)
 rankMatrix(matrix(0, 2, 2), method = .m.)) == 0)

```

rcond-methods

*Estimate the Reciprocal Condition Number*

---

## Description

Estimate the reciprocal of the condition number of a matrix.

This is a generic function with several methods, as seen by [showMethods\(rcond\)](#).

## Usage

```
rcond(x, norm, ...)
```

```
S4 method for signature 'sparseMatrix,character'
rcond(x, norm, useInv=FALSE, ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | an R object that inherits from the <code>Matrix</code> class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>norm</code>   | character string indicating the type of norm to be used in the estimate. The default is "0" for the 1-norm ("0" is equivalent to "1"). For sparse matrices, when <code>useInv=TRUE</code> , <code>norm</code> can be any of the kinds allowed for <code>norm</code> ; otherwise, the other possible value is "I" for the infinity norm, see also <code>norm</code> .                                                                                                                                                          |
| <code>useInv</code> | logical (or "Matrix" containing <code>solve(x)</code> ). If not false, compute the reciprocal condition number as $1/(\ x\  \cdot \ x^{-1}\ )$ , where $x^{-1}$ is the inverse of $x$ , <code>solve(x)</code> . This may be an efficient alternative (only) in situations where <code>solve(x)</code> is fast (or known), e.g., for (very) sparse or triangular matrices.<br>Note that the <i>result</i> may differ depending on <code>useInv</code> , as per default, when it is false, an <i>approximation</i> is computed. |
| <code>...</code>    | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Value

An estimate of the reciprocal condition number of `x`.

## BACKGROUND

The condition number of a regular (square) matrix is the product of the `norm` of the matrix and the norm of its inverse (or pseudo-inverse).

More generally, the condition number is defined (also for non-square matrices  $A$ ) as

$$\kappa(A) = \frac{\max_{\|v\|=1} \|Av\|}{\min_{\|v\|=1} \|Av\|}.$$

Whenever `x` is *not* a square matrix, in our method definitions, this is typically computed via `rcond(qr.R(qr(X)), ...)` where  $X$  is `x` or `t(x)`.

The condition number takes on values between 1 and infinity, inclusive, and can be viewed as a factor by which errors in solving linear systems with this matrix as coefficient matrix could be magnified.

`rcond()` computes the *reciprocal* condition number  $1/\kappa$  with values in  $[0, 1]$  and can be viewed as a scaled measure of how close a matrix is to being rank deficient (aka "singular").

Condition numbers are usually estimated, since exact computation is costly in terms of floating-point operations. An (over) estimate of reciprocal condition number is given, since by doing so overflow is avoided. Matrices are well-conditioned if the reciprocal condition number is near 1 and ill-conditioned if it is near zero.

## References

Golub, G., and Van Loan, C. F. (1989). *Matrix Computations*, 2nd edition, Johns Hopkins, Baltimore.

## See Also

`norm`, `kappa()` from package **base** computes an *approximate* condition number of a "traditional" matrix, even non-square ones, with respect to the  $p = 2$  (Euclidean) `norm`. `solve`.

`condest`, a newer *approximate* estimate of the (1-norm) condition number, particularly efficient for large sparse matrices.

**Examples**

```

x <- Matrix(rnorm(9), 3, 3)
rcond(x)
typically "the same" (with more computational effort):
1 / (norm(x) * norm(solve(x)))
rcond(Hilbert(9)) # should be about 9.1e-13

For non-square matrices:
rcond(x1 <- cbind(1,1:10))# 0.05278
rcond(x2 <- cbind(x1, 2:11))# practically 0, since x2 does not have full rank

sparse
(S1 <- Matrix(rbind(0:1,0, diag(3:-2))))
rcond(S1)
m1 <- as(S1, "denseMatrix")
all.equal(rcond(S1), rcond(m1))

wide and sparse
rcond(Matrix(cbind(0, diag(2:-1))))

Large sparse example -----
m <- Matrix(c(3,0:2), 2,2)
M <- bdiag(kronecker(Diagonal(2), m), kronecker(m,m))
36*(iM <- solve(M)) # still sparse
MM <- kronecker(Diagonal(10), kronecker(Diagonal(5),kronecker(m,M)))
dim(M3 <- kronecker(bdiag(M,M),MM)) # 12'800 ^ 2
if(interactive()) ## takes about 2 seconds if you have >= 8 GB RAM
system.time(r <- rcond(M3))
whereas this is *fast* even though it computes solve(M3)
system.time(r. <- rcond(M3, useInv=TRUE))
if(interactive()) ## the values are not the same
c(r, r.) # 0.05555 0.013888
for all 4 norms available for sparseMatrix :
cbind(rr <- sapply(c("1","I","F","M"),
 function(N) rcond(M3, norm=N, useInv=TRUE)))

```

rep2abI

*Replicate Vectors into 'abIndex' Result***Description**

rep2abI(x, times) conceptually computes [rep.int](#)(x, times) but with an [abIndex](#) class result.

**Usage**

```
rep2abI(x, times)
```

**Arguments**

|       |                                                    |
|-------|----------------------------------------------------|
| x     | numeric vector                                     |
| times | integer (valued) scalar: the number of repetitions |

**Value**

a vector of `class abIndex`

**See Also**

`rep.int()`, the base function; `abIseq`, `abIndex`.

**Examples**

```
(ab <- rep2abI(2:7, 4))
stopifnot(identical(as(ab, "numeric"),
 rep(2:7, 4)))
```

---

|               |                                                       |
|---------------|-------------------------------------------------------|
| rleDiff-class | <i>Class "rleDiff" of rle(diff(.)) Stored Vectors</i> |
|---------------|-------------------------------------------------------|

---

**Description**

Class "rleDiff" is for compactly storing long vectors which mainly consist of *linear* stretches. For such a vector `x`, `diff(x)` consists of *constant* stretches and is hence well compressable via `rle()`.

**Objects from the Class**

Objects can be created by calls of the form `new("rleDiff", ...)`.

Currently experimental, see below.

**Slots**

**first:** A single number (of class "numLike", a class union of "numeric" and "logical").

**rle:** Object of class "rle", basically a `list` with components "lengths" and "values", see `rle()`. As this is used to encode potentially huge index vectors, lengths may be of type `double` here.

**Methods**

There is a simple `show` method only.

**Note**

This is currently an *experimental* auxiliary class for the class `abIndex`, see there.

**See Also**

`rle`, `abIndex`.

**Examples**

```
showClass("rleDiff")

ab <- c(abIseq(2, 100), abIseq(20, -2))
ab@rleD # is "rleDiff"
```

---

|               |                             |
|---------------|-----------------------------|
| rsparsematrix | <i>Random Sparse Matrix</i> |
|---------------|-----------------------------|

---

## Description

Generate a random sparse matrix efficiently. The default has rounded gaussian non-zero entries, and `rand.x = NULL` generates random pattern matrices, i.e. inheriting from [nsparseMatrix](#).

## Usage

```
rsparsematrix(nrow, ncol, density, nnz = round(density * maxE),
 symmetric = FALSE,
 rand.x = function(n) signif(rnorm(n), 2), ...)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nrow, ncol</code> | number of rows and columns, i.e., the matrix dimension ( <a href="#">dim</a> ).                                                                                                                                                                                                                                                     |
| <code>density</code>    | optional number in $[0, 1]$ , the density is the proportion of non-zero entries among all matrix entries. If specified it determines the default for <code>nnz</code> , otherwise <code>nnz</code> needs to be specified.                                                                                                           |
| <code>nnz</code>        | number of non-zero entries, for a sparse matrix typically considerably smaller than <code>nrow*ncol</code> . Must be specified if <code>density</code> is not.                                                                                                                                                                      |
| <code>symmetric</code>  | logical indicating if result should be a matrix of class <a href="#">symmetricMatrix</a> . Note that in the symmetric case, <code>nnz</code> denotes the number of non zero entries of the upper (or lower) part of the matrix, including the diagonal.                                                                             |
| <code>rand.x</code>     | <a href="#">NULL</a> or the random number generator for the <code>x</code> slot, a <a href="#">function</a> such that <code>rand.x(n)</code> generates a numeric vector of length <code>n</code> . Typical examples are <code>rand.x = rnorm</code> , or <code>rand.x = runif</code> ; the default is nice for didactical purposes. |
| <code>...</code>        | optionally further arguments passed to <a href="#">sparseMatrix()</a> , notably <code>repr</code> .                                                                                                                                                                                                                                 |

## Details

The algorithm first samples “encoded”  $(i, j)$ s without replacement, via one dimensional indices, if not symmetric [sample.int](#)(`nrow*ncol`, `nnz`), then—if `rand.x` is not [NULL](#)—gets `x <- rand.x(nnz)` and calls [sparseMatrix](#)(`i=i`, `j=j`, `x=x`, `..`). When `rand.x=NULL`, [sparseMatrix](#)(`i=i`, `j=j`, `..`) will return a pattern matrix (i.e., inheriting from [nsparseMatrix](#)).

## Value

a [sparseMatrix](#), say `M` of dimension (`nrow`, `ncol`), i.e., with `dim(M) == c(nrow, ncol)`, if `symmetric` is not true, with `nzM <- nnzero(M)` fulfilling `nzM <= nnz` and typically, `nzM == nnz`.

## Author(s)

Martin Maechler

**Examples**

```

set.seed(17) # to be reproducible
M <- rsparsematrix(8, 12, nnz = 30) # small example, not very sparse
M
M1 <- rsparsematrix(1000, 20, nnz = 123, rand.x = runif)
summary(M1)

a random *symmetric* Matrix
(S9 <- rsparsematrix(9, 9, nnz = 10, symmetric=TRUE)) # dsCMatrix
nnzero(S9) # ~ 20: as 'nnz' only counts one "triangle"

a random pattern aka boolean Matrix (no 'x' slot):
(n7 <- rsparsematrix(5, 12, nnz = 10, rand.x = NULL))

a [T]riplet representation sparseMatrix:
T2 <- rsparsematrix(40, 12, nnz = 99, repr = "T")
head(T2)

```

|                     |                                                                        |
|---------------------|------------------------------------------------------------------------|
| RsparseMatrix-class | Class <i>"RsparseMatrix"</i> of Sparse Matrices in Row-compressed Form |
|---------------------|------------------------------------------------------------------------|

---

**Description**

The "RsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed row-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("RsparseMatrix")` for its subclasses.

**Slots**

**j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**Dim, Dimnames**: inherited from the superclass, see [sparseMatrix](#).

**Extends**

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

**Methods**

Originally, **few** methods were defined on purpose, as we rather use the [CsparseMatrix](#) in **Matrix**. Then, more methods were added but *beware* that these typically do *not* return "RsparseMatrix" results, but rather *Csparse\** or *Tsparse\** ones; e.g., `R[i, j] <- v` for an "RsparseMatrix" R works, but after the assignment, R is a (triplet) "TsparseMatrix".

```

its superclass, [sparseMatrix](#), and, e.g., class [dgRMatrix](#) for the links to other classes.

**Examples**

```
showClass("RsparseMatrix")
```

Schur-class

*Schur Factorizations***Description**

Schur is the class of Schur factorizations of  $n \times n$  real matrices  $A$ , having the general form

$$A = QTQ'$$

where  $Q$  is an orthogonal matrix and  $T$  is a block upper triangular matrix with  $1 \times 1$  or  $2 \times 2$  diagonal blocks specifying the real and complex conjugate eigenvalues of  $A$ . The column vectors of  $Q$  are the Schur vectors of  $A$ , and  $T$  is the Schur form of  $A$ .

The Schur factorization generalizes the spectral decomposition of normal matrices  $A$ , whose Schur form is block diagonal, to arbitrary square matrices.

**Details**

The matrix  $A$  and its Schur form  $T$  are *similar* and thus have the same spectrum. The eigenvalues are computed trivially as the eigenvalues of the diagonal blocks of  $T$ .

**Slots**

Dim, Dimnames inherited from virtual class [MatrixFactorization](#).

Q an orthogonal matrix, inheriting from virtual class [Matrix](#).

T a block upper triangular matrix, inheriting from virtual class [Matrix](#). The diagonal blocks have dimensions 1-by-1 or 2-by-2.

EValues a numeric or complex vector containing the eigenvalues of the diagonal blocks of T, which are the eigenvalues of T and consequently of the factorized matrix.

**Extends**

Class [SchurFactorization](#), directly. Class [MatrixFactorization](#), by class [SchurFactorization](#), distance 2.

**Instantiation**

Objects can be generated directly by calls of the form `new("Schur", ...)`, but they are more typically obtained as the value of `Schur(x)` for  $x$  inheriting from [Matrix](#) (often [dgeMatrix](#)).

**Methods**

determinant signature(from = "Schur", logarithm = "logical"): computes the determinant of the factorized matrix  $A$  or its logarithm.

expand1 signature(x = "Schur"): see [expand1-methods](#).

expand2 signature(x = "Schur"): see [expand2-methods](#).

solve signature(a = "Schur", b = .): see [solve-methods](#).

## See Also

Class [dgeMatrix](#).

Generic functions [Schur](#), [expand1](#) and [expand2](#).

## Examples

```
showClass("Schur")
set.seed(0)

n <- 4L
(A <- Matrix(rnorm(n * n), n, n))

With dimnames, to see that they are propagated :
dimnames(A) <- list(paste0("r", seq_len(n)),
 paste0("c", seq_len(n)))

(sch.A <- Schur(A))
str(e.sch.A <- expand2(sch.A), max.level = 2L)

A ~ Q T Q' in floating point
stopifnot(exprs = {
 identical(names(e.sch.A), c("Q", "T", "Q."))
 all.equal(A, with(e.sch.A, Q %*% T %*% Q.))
})

Factorization handled as factorized matrix
b <- rnorm(n)
stopifnot(all.equal(det(A), det(sch.A)),
 all.equal(solve(A, b), solve(sch.A, b)))

One of the non-general cases:
Schur(Diagonal(6L))
```

---

Schur-methods

*Methods for Schur Factorization*

---

## Description

Computes the Schur factorization of an  $n \times n$  real matrix  $A$ , which has the general form

$$A = QTQ'$$

where  $Q$  is an orthogonal matrix and  $T$  is a block upper triangular matrix with  $1 \times 1$  and  $2 \times 2$  diagonal blocks specifying the real and complex conjugate eigenvalues of  $A$ . The column vectors of  $Q$  are the Schur vectors of  $A$ , and  $T$  is the Schur form of  $A$ .

Methods are built on LAPACK routine dgees.

**Usage**

```
Schur(x, vectors = TRUE, ...)
```

**Arguments**

|                      |                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------|
| <code>x</code>       | a <a href="#">finite</a> square matrix or <a href="#">Matrix</a> to be factorized.               |
| <code>vectors</code> | a logical. If TRUE (the default), then Schur vectors are computed in addition to the Schur form. |
| <code>...</code>     | further arguments passed to or from methods.                                                     |

**Value**

An object representing the factorization, inheriting from virtual class [SchurFactorization](#) if `vectors = TRUE`. Currently, the specific class is always [Schur](#) in that case. An exception is if `x` is a traditional matrix, in which case the result is a named list containing Q, T, and EValues slots of the [Schur](#) object.

If `vectors = FALSE`, then the result is the same named list but without Q.

**Examples**

```
showMethods("Schur", inherited = FALSE)
set.seed(0)

Schur(Hilbert(9L)) # real eigenvalues

(A <- Matrix(round(rnorm(25L, sd = 100)), 5L, 5L))
(sch.A <- Schur(A)) # complex eigenvalues

A ~ Q T Q' in floating point
str(e.sch.A <- expand2(sch.A), max.level = 2L)
stopifnot(all.equal(A, Reduce(`%*%`, e.sch.A)))

(e1 <- eigen(sch.A@T, only.values = TRUE)$values)
(e2 <- eigen(A, only.values = TRUE)$values)
(e3 <- sch.A@EValues)

stopifnot(exprs = {
 all.equal(e1, e2, tolerance = 1e-13)
```

```

all.equal(e1, e3[order(Mod(e3), decreasing = TRUE)], tolerance = 1e-13)
identical(Schur(A, vectors = FALSE),
 list(T = sch.A@T, EValues = e3))
identical(Schur(as(A, "matrix")),
 list(Q = as(sch.A@Q, "matrix"),
 T = as(sch.A@T, "matrix"), EValues = e3))
})

```

solve(a, b, ...)
S4 method for signature 'CHMfactor,dgCMatrix'
solve(a, b, system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), ...)

```

## Arguments

**a** a [finite](#) square matrix or [Matrix](#) containing the coefficients of the linear system, or otherwise a [MatrixFactorization](#), in which case methods behave (by default) as if the factorized matrix were specified.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>b</code>      | a vector, <a href="#">sparseVector</a> , matrix, or <a href="#">Matrix</a> satisfying <code>NROW(b) == nrow(a)</code> , giving the right-hand side(s) of the linear system. Vectors <code>b</code> are treated as <code>length(b)-by-1</code> matrices. If <code>b</code> is missing, then methods take <code>b</code> to be an identity matrix.                                                                                                                                                                                                                                                                                                                                                    |
| <code>tol</code>    | a non-negative number. For <code>a</code> inheriting from <a href="#">denseMatrix</a> , an error is signaled if the reciprocal one-norm condition number (see <a href="#">rcond</a> ) of <code>a</code> is less than <code>tol</code> , indicating that <code>a</code> is near-singular. For <code>a</code> of class <a href="#">sparseLU</a> , an error is signaled if the ratio <code>min(d)/max(d)</code> is less than <code>tol</code> , where <code>d = abs(diag(a@U))</code> . (Interpret with care, as this ratio is a cheap heuristic and <i>not</i> in general equal to or even proportional to the reciprocal one-norm condition number.) Setting <code>tol = 0</code> disables the test. |
| <code>sparse</code> | a logical indicating if the result should be formally sparse, i.e., if the result should inherit from virtual class <a href="#">sparseMatrix</a> . Only methods for sparse <code>a</code> and missing or matrix <code>b</code> have this argument. Methods for missing or sparse <code>b</code> use <code>sparse = TRUE</code> by default. Methods for dense <code>b</code> use <code>sparse = FALSE</code> by default.                                                                                                                                                                                                                                                                             |
| <code>system</code> | a string specifying a linear system to be solved. Only methods for <code>a</code> inheriting from <a href="#">CHMfactor</a> have this argument. See ‘Details’.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>...</code>    | further arguments passed to or from methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

Methods for general and symmetric matrices `a` compute a triangular factorization (LU, Bunch-Kaufman, or Cholesky) and call the method for the corresponding factorization class. The factorization is sparse if `a` is. Methods for sparse, symmetric matrices `a` attempt a Cholesky factorization and perform an LU factorization only if that fails (typically because `a` is not positive definite).

Triangular, diagonal, and permutation matrices do not require factorization (they are already “factors”), hence methods for those are implemented directly. For triangular `a`, solutions are obtained by forward or backward substitution; for diagonal `a`, they are obtained by scaling the rows of `b`; and for permutations `a`, they are obtained by permuting the rows of `b`.

Methods for dense `a` are built on 14 LAPACK routines: class `d..Matrix`, where `..=(ge|tr|tp|sy|sp|po|pp)`, uses routines `d..tri` and `d..trs` for missing and non-missing `b`, respectively. A corollary is that these methods always give a dense result.

Methods for sparse `a` are built on CXSparse routines `cs_lsolve`, `cs_usolve`, and `cs_spsolve` and CHOLMOD routines `cholmod_solve` and `cholmod_spsolve`. By default, these methods give a vector result if `b` is a vector, a sparse matrix result if `b` is missing or a sparse matrix, and a dense matrix result if `b` is a dense matrix. One can override this behaviour by setting the `sparse` argument, where available, but that should be done with care. Note that a sparse result may be sparse only in the formal sense and not at all in the mathematical sense, depending on the nonzero patterns of `a` and `b`. Furthermore, whereas dense results are fully preallocated, sparse results must be “grown” in a loop over the columns of `b`.

Methods for `a` of class [sparseQR](#) are simple wrappers around `qr.coef`, giving the *least squares* solution in overdetermined cases.

Methods for `a` inheriting from [CHMfactor](#) can solve systems other than the default one  $AX = B$ . The correspondence between its `system` argument the system actually solved is outlined in the table below. See [CHMfactor-class](#) for a definition of notation.

| system | <code>isLDL(a)=TRUE</code> | <code>isLDL(a)=FALSE</code> |
|--------|----------------------------|-----------------------------|
| "A"    | $AX = B$                   | $AX = B$                    |
| "LDLt" | $L_1 D L_1' X = B$         | $LL' X = B$                 |

## Examples

```
A close to symmetric example with "quite sparse" inverse:
n1 <- 7; n2 <- 3
dd <- data.frame(a = gl(n1,n2), b = gl(n2,1,n1*n2))# balanced 2-way
X <- sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
XXt <- tcrossprod(X)
diag(XXt) <- rep(c(0,0,1,0), length.out = nrow(XXt))

n <- nrow(ZZ <- kronecker(XXt, Diagonal(x=c(4,1))))
image(a <- 2*Diagonal(n) + ZZ %*% Diagonal(x=c(10, rep(1, n-1))))
isSymmetric(a) # FALSE
image(drop0(skewpart(a)))
image(ia0 <- solve(a, tol = 0)) # checker board, dense [but really, a is singular!]
try(solve(a, sparse=TRUE))##-> error [TODO: assertError]
ia. <- solve(a, sparse=TRUE, tol = 1e-19)##-> *no* error
if(R.version$arch == "x86_64")
 ## Fails on 32-bit [Fedora 19, R 3.0.2] from Matrix 1.1-0 on [FIXME ??] only
 stopifnot(all.equal(as.matrix(ia.), as.matrix(ia0)))
a <- a + Diagonal(n)
iad <- solve(a)
ias <- solve(a, sparse=FALSE)
stopifnot(all.equal(as(iad,"denseMatrix"), ias, tolerance=1e-14))
I. <- iad %*% a ; image(I.)
I0 <- drop0(zapsmall(I.)); image(I0)
.I <- a %*% iad
.I0 <- drop0(zapsmall(.I))
stopifnot(all.equal(as(I0, "diagonalMatrix"), Diagonal(n)),
 all.equal(as(.I0,"diagonalMatrix"), Diagonal(n)))
```

## Description

Construct a sparse model or “design” matrix, from a formula and data frame (`sparse.model.matrix`) or a single factor (`fac2sparse`).

The `fac2[Ss]parse()` functions are utilities, also used internally in the principal user level function `sparse.model.matrix()`.

## Usage

```
sparse.model.matrix(object, data = environment(object),
 contrasts.arg = NULL, xlev = NULL, transpose = FALSE,
 drop.unused.levels = FALSE, row.names = TRUE,
 sep = "", verbose = FALSE, ...)

fac2sparse(from, to = c("d", "l", "n"),
 drop.unused.levels = TRUE, repr = c("C", "R", "T"), giveCsparse)
fac2Sparse(from, to = c("d", "l", "n"),
 drop.unused.levels = TRUE, repr = c("C", "R", "T"), giveCsparse,
 factorPatt12, contrasts.arg = NULL)
```

## Arguments

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>             | an object of an appropriate class. For the default method, a model formula or terms object.                                                                                                                                                                                                                                                                                                                                               |
| <code>data</code>               | a data frame created with <code>model.frame</code> . If another sort of object, <code>model.frame</code> is called first.                                                                                                                                                                                                                                                                                                                 |
| <code>contrasts.arg</code>      | <b>for</b> <code>sparse.model.matrix()</code> : A list, whose entries are contrasts suitable for input to the <code>contrasts</code> replacement function and whose names are the names of columns of data containing <code>factors</code> .<br><b>for</b> <code>fac2Sparse()</code> : character string or <code>NULL</code> or (coercable to) <code>"sparseMatrix"</code> , specifying the contrasts to be applied to the factor levels. |
| <code>xlev</code>               | to be used as argument of <code>model.frame</code> if data has no <code>"terms"</code> attribute.                                                                                                                                                                                                                                                                                                                                         |
| <code>transpose</code>          | logical indicating if the <i>transpose</i> should be returned; if the transposed is used anyway, setting <code>transpose = TRUE</code> is more efficient.                                                                                                                                                                                                                                                                                 |
| <code>drop.unused.levels</code> | should factors have unused levels dropped? The default for <code>sparse.model.matrix</code> has been changed to <code>FALSE</code> , 2010-07, for compatibility with R's standard (dense) <code>model.matrix()</code> .                                                                                                                                                                                                                   |
| <code>row.names</code>          | logical indicating if row names should be used.                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>sep</code>                | <code>character</code> string passed to <code>paste()</code> when constructing column names from the variable name and its levels.                                                                                                                                                                                                                                                                                                        |
| <code>verbose</code>            | logical or integer indicating if (and how much) progress output should be printed.                                                                                                                                                                                                                                                                                                                                                        |
| <code>...</code>                | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>from</code>               | (for <code>fac2sparse()</code> ): a <code>factor</code> .                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>to</code>                 | a character indicating the “kind” of sparse matrix to be returned. The default, <code>"d"</code> is for <code>double</code> .                                                                                                                                                                                                                                                                                                             |
| <code>giveCsparse</code>        | <b>deprecated</b> , replaced with <code>repr</code> ; logical indicating if the result must be a <code>CsparseMatrix</code> .                                                                                                                                                                                                                                                                                                             |

`repr` [character](#) string, one of "C", "T", or "R", specifying the sparse *representation* to be used for the result, i.e., one from the super classes [CsparseMatrix](#), [TsparseMatrix](#), or [RsparseMatrix](#).

`factorPatt12` logical vector, say `fp`, of length two; when `fp[1]` is true, return “contrasted” `t(X)`; when `fp[2]` is true, the original (“dummy”) `t(X)`, i.e, the result of `fac2sparse()`.

### Value

a sparse matrix, extending [CsparseMatrix](#) (for `fac2sparse()` if `repr = "C"` as per default; a [TsparseMatrix](#) or [RsparseMatrix](#), otherwise).

For `fac2Sparse()`, a [list](#) of length two, both components with the corresponding transposed model matrix, where the corresponding `factorPatt12` is true.

`fac2sparse()`, the basic workhorse of `sparse.model.matrix()`, returns the *transpose* ([t](#)) of the model matrix.

### Note

`model.Matrix(sparse = TRUE)` from package **MatrixModels** may be nowadays be preferable to `sparse.model.matrix`, as `model.Matrix` returns an object of class `modelMatrix` with additional slots `assign` and `contrasts` relating to the model variables.

### Author(s)

Doug Bates and Martin Maechler, with initial suggestions from Tim Hesterberg.

### See Also

[model.matrix](#) in package **stats**, part of base R.

`model.Matrix` in package **MatrixModels**; see ‘Note’.

`as(f, "sparseMatrix")` (see `coerce(from = "factor", ...)` in the class doc [sparseMatrix](#)) produces the *transposed* sparse model matrix for a single factor `f` (and *no* contrasts).

### Examples

```
dd <- data.frame(a = gl(3,4), b = gl(4,1,12))# balanced 2-way
options("contrasts") # the default: "contr.treatment"
sparse.model.matrix(~ a + b, dd)
sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
sparse.model.matrix(~ a + b, dd, contrasts = list(a="contr.sum"))
sparse.model.matrix(~ a + b, dd, contrasts = list(b="contr.SAS"))

Sparse method is equivalent to the traditional one :
stopifnot(all(sparse.model.matrix(~ a + b, dd) ==
 Matrix(model.matrix(~ a + b, dd), sparse=TRUE)),
 all(sparse.model.matrix(~0 + a + b, dd) ==
 Matrix(model.matrix(~0 + a + b, dd), sparse=TRUE)))

(ff <- gl(3,4,, c("X","Y", "Z")))
fac2sparse(ff) # 3 x 12 sparse Matrix of class "dgCMatrix"
##
X 1 1 1 1
Y 1 1 1 1 . . .
Z 1 1 1 1
```

```
can also be computed via sparse.model.matrix():
f30 <- gl(3,0)
f12 <- gl(3,0, 12)
stopifnot(
 all.equal(t(fac2sparse(ff)),
 sparse.model.matrix(~ 0+ff),
 tolerance = 0, check.attributes=FALSE),
 is(M <- fac2sparse(f30, drop= TRUE),"CsparseMatrix"), dim(M) == c(0, 0),
 is(M <- fac2sparse(f30, drop=FALSE),"CsparseMatrix"), dim(M) == c(3, 0),
 is(M <- fac2sparse(f12, drop= TRUE),"CsparseMatrix"), dim(M) == c(0,12),
 is(M <- fac2sparse(f12, drop=FALSE),"CsparseMatrix"), dim(M) == c(3,12)
)
```

---

sparseLU-class

---

*Sparse LU Factorizations*

---

## Description

sparseLU is the class of sparse, row- and column-pivoted LU factorizations of  $n \times n$  real matrices  $A$ , having the general form

$$P_1 A P_2 = L U$$

or (equivalently)

$$A = P_1' L U P_2'$$

where  $P_1$  and  $P_2$  are permutation matrices,  $L$  is a unit lower triangular matrix, and  $U$  is an upper triangular matrix.

## Slots

Dim, Dimnames inherited from virtual class [MatrixFactorization](#).

L an object of class [dtCMatrix](#), the unit lower triangular  $L$  factor.

U an object of class [dtCMatrix](#), the upper triangular  $U$  factor.

p, q 0-based integer vectors of length Dim[1], specifying the permutations applied to the rows and columns of the factorized matrix. q of length 0 is valid and equivalent to the identity permutation, implying no column pivoting. Using **R** syntax, the matrix  $P_1 A P_2$  is precisely  $A[p+1, q+1]$  ( $A[p+1, ]$  when q has length 0).

## Extends

Class [LU](#), directly. Class [MatrixFactorization](#), by class [LU](#), distance 2.

## Instantiation

Objects can be generated directly by calls of the form `new("sparseLU", ...)`, but they are more typically obtained as the value of `lu(x)` for  $x$  inheriting from [sparseMatrix](#) (often [dgCMatrix](#)).

## Methods

determinant signature(from = "sparseLU", logarithm = "logical"): computes the determinant of the factorized matrix  $A$  or its logarithm.

expand signature(x = "sparseLU"): see [expand-methods](#).

expand1 signature(x = "sparseLU"): see [expand1-methods](#).

expand2 signature(x = "sparseLU"): see [expand2-methods](#).

solve signature(a = "sparseLU", b = .): see [solve-methods](#).

---

sparseMatrix

General Sparse Matrix Construction from Nonzero Entries

---

## Description

User-friendly construction of sparse matrices (inheriting from virtual [class CsparseMatrix](#), [RsparseMatrix](#), or [TsparseMatrix](#)) from the positions and values of their nonzero entries.

This interface is recommended over direct construction via calls such as [new\(".\[CRT\]Matrix", ...\)](#).

## Usage

```

sparseMatrix(i, j, p, x, dims, dimnames,
 symmetric = FALSE, triangular = FALSE, index1 = TRUE,
 repr = c("C", "R", "T"), giveCsparse,
 check = TRUE, use.last.ij = FALSE)

```

## Arguments

- |            |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| i, j       | integer vectors of equal length specifying the positions (row and column indices) of the nonzero (or non-TRUE) entries of the matrix. Note that, when x is non-missing, the $x_k$ corresponding to <i>repeated</i> pairs $(i_k, j_k)$ are <i>added</i> , for consistency with the definition of class <a href="#">TsparseMatrix</a> , unless <code>use.last.ij</code> is TRUE, in which case only the <i>last</i> such $x_k$ is used. |
| p          | integer vector of pointers, one for each column (or row), to the initial (zero-based) index of elements in the column (or row). Exactly one of i, j, and p must be missing.                                                                                                                                                                                                                                                           |
| x          | optional, typically nonzero values for the matrix entries. If specified, then the length must equal that of i (or j) or equal 1, in which case x is recycled as necessary. If missing, then the result is a <b>nonzero</b> pattern matrix, i.e., inheriting from class <a href="#">nsparseMatrix</a> .                                                                                                                                |
| dims       | optional length-2 integer vector of matrix dimensions. If missing, then <code>!index1+c(max(i),max(j))</code> is used.                                                                                                                                                                                                                                                                                                                |
| dimnames   | optional list of <a href="#">dimnames</a> ; if missing, then <a href="#">NULL</a> ones are used.                                                                                                                                                                                                                                                                                                                                      |
| symmetric  | logical indicating if the resulting matrix should be symmetric. In that case, $(i, j, p)$ should specify only one triangle (upper or lower).                                                                                                                                                                                                                                                                                          |
| triangular | logical indicating if the resulting matrix should be triangular. In that case, $(i, j, p)$ should specify only one triangle (upper or lower).                                                                                                                                                                                                                                                                                         |
| index1     | logical. If TRUE (the default), then i and j are interpreted as 1-based indices, following the R convention. That is, counting of rows and columns starts at 1. If FALSE, then they are interpreted as 0-based indices.                                                                                                                                                                                                               |

|             |                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| repr        | <a href="#">character</a> string, one of "C", "R", and "T", specifying the <b>representation</b> of the sparse matrix result, i.e., specifying one of the virtual classes <a href="#">CsparseMatrix</a> , <a href="#">RsparseMatrix</a> , and <a href="#">TsparseMatrix</a> . |
| giveCsparse | <b>(deprecated)</b> , replaced by repr) logical indicating if the result should inherit from <a href="#">CsparseMatrix</a> or <a href="#">TsparseMatrix</a> . Note that operations involving <a href="#">CsparseMatrix</a> are very often (but not always) more efficient.    |
| check       | logical indicating whether to check that the result is formally valid before returning. Do not set to FALSE unless you know what you are doing!                                                                                                                               |
| use.last.ij | logical indicating if, in the case of repeated (duplicated) pairs $(i_k, j_k)$ , only the last pair should be used. FALSE (the default) is consistent with the definition of class <a href="#">TsparseMatrix</a> .                                                            |

## Details

Exactly one of the arguments i, j and p must be missing.

In typical usage, p is missing, i and j are vectors of positive integers and x is a numeric vector. These three vectors, which must have the same length, form the triplet representation of the sparse matrix.

If i or j is missing then p must be a non-decreasing integer vector whose first element is zero. It provides the compressed, or “pointer” representation of the row or column indices, whichever is missing. The expanded form of p, `rep(seq_along(dp), dp)` where `dp <- diff(p)`, is used as the (1-based) row or column indices.

You cannot set both singular and triangular to true; rather use [Diagonal\(\)](#) (or its alternatives, see there).

The values of i, j, p and index1 are used to create 1-based index vectors i and j from which a [TsparseMatrix](#) is constructed, with numerical values given by x, if non-missing. Note that in that case, when some pairs  $(i_k, j_k)$  are repeated (aka “duplicated”), the corresponding  $x_k$  are *added*, in consistency with the definition of the [TsparseMatrix](#) class, unless `use.last.ij` is set to true.

By default, when `repr = "C"`, the [CsparseMatrix](#) derived from this triplet form is returned, where `repr = "R"` now allows to directly get an [RsparseMatrix](#) and `repr = "T"` leaves the result as [TsparseMatrix](#).

The reason for returning a [CsparseMatrix](#) object instead of the triplet format by default is that the compressed column form is easier to work with when performing matrix operations. In particular, if there are no zeros in x then a [CsparseMatrix](#) is a unique representation of the sparse matrix.

## Value

A sparse matrix, by default in compressed sparse column format and (formally) without symmetric or triangular structure, i.e., by default inheriting from both [CsparseMatrix](#) and [generalMatrix](#).

## Note

You *do* need to use `index1 = FALSE` (or add + 1 to i and j) if you want use the 0-based i (and j) slots from existing sparse matrices.

## See Also

[Matrix](#)(\*, sparse=TRUE) for the constructor of such matrices from a *dense* matrix. That is easier in small sample, but much less efficient (or impossible) for large matrices, where something like `sparseMatrix()` is needed. Further [bdiag](#) and [Diagonal](#) for (block-)diagonal and [bandSparse](#) for banded sparse matrix constructors.

Random sparse matrices via `rsparsematrix()`.

The standard R `xtabs(*, sparse=TRUE)`, for sparse tables and `sparse.model.matrix()` for building sparse model matrices.

Consider `CsparseMatrix` and similar class definition help files.

## Examples

```
simple example
i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(A <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"
summary(A)
str(A) # note that *internally* 0-based row indices are used

(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"
(tA <- sparseMatrix(i, j, x = x, triangular= TRUE)) ## 10 x 10 "dtCMatrix"
stopifnot(all(sA == tA + t(tA)) ,
 identical(sA, as(tA + t(tA), "symmetricMatrix")))

dims can be larger than the maximum row or column indices
(AA <- sparseMatrix(c(1,3:8), c(2,9,6:10), x = 7 * (1:7), dims = c(10,20)))
summary(AA)

i, j and x can be in an arbitrary order, as long as they are consistent
set.seed(1); (perm <- sample(1:7))
(A1 <- sparseMatrix(i[perm], j[perm], x = x[perm]))
stopifnot(identical(A, A1))

The slots are 0-index based, so
try(sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x)))
fails and you should say so: 1-indexing is FALSE:
 sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x), index1 = FALSE)

the (i,j) pairs can be repeated, in which case the x's are summed
(args <- data.frame(i = c(i, 1), j = c(j, 2), x = c(x, 2)))
(Aa <- do.call(sparseMatrix, args))
explicitly ask for elimination of such duplicates, so
that the last one is used:
(A. <- do.call(sparseMatrix, c(args, list(use.last.ij = TRUE))))
stopifnot(Aa[1,2] == 9, # 2+7 == 9
 A.[1,2] == 2) # 2 was *after* 7

for a pattern matrix, of course there is no "summing":
(nA <- do.call(sparseMatrix, args[c("i","j")]))

dn <- list(LETTERS[1:3], letters[1:5])
pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p= c(0:2, 4,4,6), x = 1:6, dimnames = dn)
m
str(m)
stopifnot(identical(dimnames(m), dn))

sparseMatrix(x = 2.72, i=1:3, j=2:4) # recycling x
sparseMatrix(x = TRUE, i=1:3, j=2:4) # recycling x, |--> "lgCMatrix"

no 'x' --> patter*n* matrix:
(n <- sparseMatrix(i=1:6, j=rev(2:7)))# -> ngCMatrix
```

```
an empty sparse matrix:
(e <- sparseMatrix(dims = c(4,6), i={}, j={}))

a symmetric one:
(sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5,
 dims = c(7,7), symmetric=TRUE))
stopifnot(isSymmetric(sy),
 identical(sy, ## switch i <-> j {and transpose }
 t(sparseMatrix(j= c(2,4,3:5), i= c(4,7:5,5), x = 1:5,
 dims = c(7,7), symmetric=TRUE))))

rsparsematrix() calls sparseMatrix() :
M1 <- rsparsematrix(1000, 20, nnz = 200)
summary(M1)

pointers example in converting from other sparse matrix representations.
if(requireNamespace("SparseM") &&
 packageVersion("SparseM") >= "0.87" &&
 nzchar(dfil <- system.file("extdata", "rua_32_ax.rua", package = "SparseM"))) {
 X <- SparseM::model.matrix(SparseM::read.matrix.hb(dfil))
 XX <- sparseMatrix(j = X@ja, p = X@ia - 1L, x = X@ra, dims = X@dimension)
 validObject(XX)

 ## Alternatively, and even more user friendly :
 X. <- as(X, "Matrix") # or also
 X2 <- as(X, "sparseMatrix")
 stopifnot(identical(XX, X.), identical(X., X2))
}
```

sparseMatrix-class

Virtual Class "sparseMatrix" — Mother of Sparse Matrices

## Description

Virtual Mother Class of All Sparse Matrices

## Slots

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** a list of length two - inherited from class `Matrix`, see [Matrix](#).

## Extends

Class "Matrix", directly.

## Methods

**show** (object = "sparseMatrix"): The [show](#) method for sparse matrices prints “*structural*” zeroes as “.” using [printSpMatrix\(\)](#) which allows further customization.

**print** signature(x = "sparseMatrix"), ....

The [print](#) method for sparse matrices by default is the same as `show()` but can be called with extra optional arguments, see [printSpMatrix\(\)](#).

**format** signature(x = "sparseMatrix"), ...

The **format** method for sparse matrices, see **formatSpMatrix()** for details such as the extra optional arguments.

**summary** (object = "sparseMatrix", uniqT=FALSE): Returns an object of S3 class "sparseSummary" which is basically a **data.frame** with columns (i,j,x) (or just (i,j) for **nsparseMatrix** class objects) with the stored (typically non-zero) entries. The **print** method resembles Matlab's way of printing sparse matrices, and also the MatrixMarket format, see **writeMM**.

**cbind2** (x = \*, y = \*): several methods for binding matrices together, column-wise, see the basic **cbind** and **rbind** functions.

Note that the result will typically be sparse, even when one argument is dense and larger than the sparse one.

**rbind2** (x = \*, y = \*): binding matrices together row-wise, see **cbind2** above.

**determinant** (x = "sparseMatrix", logarithm=TRUE): **determinant()** methods for sparse matrices typically work via **Cholesky** or **lu** decompositions.

**diag** (x = "sparseMatrix"): extracts the diagonal of a sparse matrix.

**dim<-** signature(x = "sparseMatrix", value = "ANY"): allows to *reshape* a sparse matrix to a sparse matrix with the same entries but different dimensions. value must be of length two and fulfill `prod(value) == prod(dim(x))`.

**coerce** signature(from = "factor", to = "sparseMatrix"): Coercion of a factor to "sparseMatrix" produces the matrix of indicator **rows** stored as an object of class "dgCMatrix". To obtain columns representing the interaction of the factor and a numeric covariate, replace the "x" slot of the result by the numeric covariate then take the transpose. Missing values (**NA**) from the factor are translated to columns of all 0s.

See also **colSums**, **norm**, ... for methods with separate help pages.

## Note

In method selection for multiplication operations (i.e. **%%** and the two-argument form of **crossprod**) the **sparseMatrix** class takes precedence in the sense that if one operand is a sparse matrix and the other is any type of dense matrix then the dense matrix is coerced to a **dgeMatrix** and the appropriate sparse matrix method is used.

## See Also

**sparseMatrix**, and its references, such as **xtabs**(\*, sparse=TRUE), or **sparse.model.matrix()**, for constructing sparse matrices.

**T2graph** for conversion of "graph" objects (package **graph**) to and from sparse matrices.

## Examples

```
showClass("sparseMatrix") ## and look at the help() of its subclasses
M <- Matrix(0, 10000, 100)
M[1,1] <- M[2,3] <- 3.14
M ## show(.) method suppresses printing of the majority of rows

data(CAex, package = "Matrix")
dim(CAex) # 72 x 72 matrix
determinant(CAex) # works via sparse lu(.)

factor -> t(<sparse design matrix>) :
```

```
(fact <- gl(5, 3, 30, labels = LETTERS[1:5]))
(Xt <- as(fact, "sparseMatrix")) # indicator rows

missing values --> all-0 columns:
f.mis <- fact
i.mis <- c(3:5, 17)
is.na(f.mis) <- i.mis
Xt != (X. <- as(f.mis, "sparseMatrix")) # differ only in columns 3:5,17
stopifnot(all(X[,i.mis] == 0), all(Xt[, -i.mis] == X[, -i.mis]))
```

sparseQR-class

*Sparse QR Factorizations*

### Description

sparseQR is the class of sparse, row- and column-pivoted QR factorizations of  $m \times n$  ( $m \geq n$ ) real matrices, having the general form

$$P_1 A P_2 = Q R = \begin{bmatrix} Q_1 & Q_2 \end{bmatrix} \begin{bmatrix} R_1 \\ 0 \end{bmatrix} = Q_1 R_1$$

or (equivalently)

$$A = P_1' Q R P_2' = P_1' \begin{bmatrix} Q_1 & Q_2 \end{bmatrix} \begin{bmatrix} R_1 \\ 0 \end{bmatrix} P_2' = P_1' Q_1 R_1 P_2'$$

where  $P_1$  and  $P_2$  are permutation matrices,  $Q = \prod_{j=1}^n H_j$  is an  $m \times m$  orthogonal matrix ( $Q_1$  contains the first  $n$  column vectors) equal to the product of  $n$  Householder matrices  $H_j$ , and  $R$  is an  $m \times n$  upper trapezoidal matrix ( $R_1$  contains the first  $n$  row vectors and is upper *triangular*).

### Usage

```
qrR(qr, complete = FALSE, backPermute = TRUE, row.names = TRUE)
```

### Arguments

|             |                                                                                                                                                                                |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| qr          | an object of class <code>sparseQR</code> , almost always the result of a call to generic function <code>qr</code> with sparse <code>x</code> .                                 |
| complete    | a logical indicating if $R$ should be returned instead of $R_1$ .                                                                                                              |
| backPermute | a logical indicating if $R$ or $R_1$ should be multiplied on the right by $P_2'$ .                                                                                             |
| row.names   | a logical indicating if <code>dimnames(qr)[1]</code> should be propagated unpermuted to the result. If <code>complete = FALSE</code> , then only the first $n$ names are kept. |

### Details

The method for `qr.Q` does not return  $Q$  but rather the (also orthogonal) product  $P_1' Q$ . This behaviour is algebraically consistent with the **base** implementation (see `qr`), which can be seen by noting that `qr.default` in **base** does not pivot rows, constraining  $P_1$  to be an identity matrix. It follows that `qr.Q(qr.default(x))` also returns  $P_1' Q$ .

Similarly, the methods for `qr.qy` and `qr.qty` multiply on the left by  $P_1' Q$  and  $Q' P_1$  rather than  $Q$  and  $Q'$ .

It is wrong to expect the values of `qr.Q` (or `qr.R`, `qr.qy`, `qr.qty`) computed from “equivalent” sparse and dense factorizations (say, `qr(x)` and `qr(as(x, "matrix"))`) for `x` of class `dgCMatrix` to compare equal. The underlying factorization algorithms are quite different, notably as they employ different pivoting strategies, and in general the factorization is not unique even for fixed  $P_1$  and  $P_2$ .

On the other hand, the values of `qr.X`, `qr.coef`, `qr.fitted`, and `qr.resid` are well-defined, and in those cases the sparse and dense computations *should* compare equal (within some tolerance).

The method for `qr.R` is a simple wrapper around `qrR`, but not back-permuting by default and never giving row names. It did not support `backPermute = TRUE` until **Matrix** 1.6-0, hence code needing the back-permuted result should call `qrR` if **Matrix**  $\geq$  1.6-0 is not known.

## Slots

`Dim`, `Dimnames` inherited from virtual class `MatrixFactorization`.

`beta` a numeric vector of length `Dim[2]`, used to construct Householder matrices; see `V` below.

`V` an object of class `dgCMatrix` with `Dim[2]` columns. The number of rows `nrow(V)` is at least `Dim[1]` and at most `Dim[1]+Dim[2]`. `V` is lower trapezoidal, and its column vectors generate the Householder matrices  $H_j$  that compose the orthogonal  $Q$  factor. Specifically,  $H_j$  is constructed as `diag(Dim[1]) - beta[j] * tcrossprod(V[, j])`.

`R` an object of class `dgCMatrix` with `nrow(V)` rows and `Dim[2]` columns. `R` is the upper trapezoidal  $R$  factor.

`p`, `q` 0-based integer vectors of length `nrow(V)` and `Dim[2]`, respectively, specifying the permutations applied to the rows and columns of the factorized matrix. `q` of length 0 is valid and equivalent to the identity permutation, implying no column pivoting. Using `R` syntax, the matrix  $P_1 A P_2$  is precisely `A[p+1, q+1]` (`A[p+1, ]` when `q` has length 0).

## Extends

Class `QR`, directly. Class `MatrixFactorization`, by class `QR`, distance 2.

## Instantiation

Objects can be generated directly by calls of the form `new("sparseQR", ...)`, but they are more typically obtained as the value of `qr(x)` for `x` inheriting from `sparseMatrix` (often `dgCMatrix`).

## Methods

`determinant` signature(`from = "sparseQR"`, `logarithm = "logical"`): computes the determinant of the factorized matrix  $A$  or its logarithm.

`expand1` signature(`x = "sparseQR"`): see [expand1-methods](#).

`expand2` signature(`x = "sparseQR"`): see [expand2-methods](#).

`qr.Q` signature(`qr = "sparseQR"`): returns as a `dgeMatrix` either  $P_1' Q$  or  $P_1' Q_1$ , depending on optional argument `complete`. The default is `FALSE`, indicating  $P_1' Q_1$ .

`qr.R` signature(`qr = "sparseQR"`): `qrR` returns  $R$ ,  $R_1$ ,  $R P_2'$ , or  $R_1 P_2'$ , depending on optional arguments `complete` and `backPermute`. The default in both cases is `FALSE`, indicating  $R_1$ , for compatibility with **base**. The class of the result in that case is `dtCMatrix`. In the other three cases, it is `dgCMatrix`.

`qr.X` signature(`qr = "sparseQR"`): returns  $A$  as a `dgeMatrix`, by default. If  $m > n$  and optional argument `ncol` is greater than  $n$ , then the result is augmented with  $P_1' Q J$ , where  $J$  is composed of columns  $(n + 1)$  through `ncol` of the  $m \times m$  identity matrix.

`qr.coef` signature(`qr = "sparseQR"`, `y = .`): returns as a [dgeMatrix](#) or vector the result of multiplying `y` on the left by  $P_2 R_1^{-1} Q_1' P_1$ .

`qr.fitted` signature(`qr = "sparseQR"`, `y = .`): returns as a [dgeMatrix](#) or vector the result of multiplying `y` on the left by  $P_1' Q_1 Q_1' P_1$ .

`qr.resid` signature(`qr = "sparseQR"`, `y = .`): returns as a [dgeMatrix](#) or vector the result of multiplying `y` on the left by  $P_1' Q_2 Q_2' P_1$ .

`qr.qty` signature(`qr = "sparseQR"`, `y = .`): returns as a [dgeMatrix](#) or vector the result of multiplying `y` on the left by  $Q' P_1$ .

`qr.qy` signature(`qr = "sparseQR"`, `y = .`): returns as a [dgeMatrix](#) or vector the result of multiplying `y` on the left by  $P_1' Q$ .

`solve` signature(`a = "sparseQR"`, `b = .`): see [solve-methods](#).

## Examples

```
showClass("sparseQR")
set.seed(2)

m <- 300L
n <- 60L
A <- rsparsematrix(m, n, 0.05)

With dimnames, to see that they are propagated :
dimnames(A) <- dn <- list(paste0("r", seq_len(m)),
 paste0("c", seq_len(n)))

(qr.A <- qr(A))
str(e.qr.A <- expand2(qr.A, complete = FALSE), max.level = 2L)
str(E.qr.A <- expand2(qr.A, complete = TRUE), max.level = 2L)

t(sapply(e.qr.A, dim))
t(sapply(E.qr.A, dim))

Horribly inefficient, but instructive :
slowQ <- function(V, beta) {
 d <- dim(V)
```

```

Q <- diag(d[1L])
if(d[2L] > 0L) {
 for(j in d[2L]:1L) {
 cat(j, "\n", sep = "")
 Q <- Q - (beta[j] * tcrossprod(V[, j])) %*% Q
 }
}
Q

}

ae1 <- function(a, b, ...) all.equal(as(a, "matrix"), as(b, "matrix"), ...)
ae2 <- function(a, b, ...) ae1(unname(a), unname(b), ...)

A ~ P1' Q R P2' ~ P1' Q1 R1 P2' in floating point
stopifnot(exprs = {
 identical(names(e.qr.A), c("P1.", "Q1", "R1", "P2."))
 identical(names(E.qr.A), c("P1.", "Q", "R", "P2."))
 identical(e.qr.A[["P1."]],
 new("pMatrix", Dim = c(m, m), Dimnames = c(dn[1L], list(NULL)),
 margin = 1L, perm = invertPerm(qr.A@p, 0L, 1L)))
 identical(e.qr.A[["P2."]],

 ae2(qrc, qr.coef(qr.Am, b))
 ae2(qrf, qr.fitted(qr.Am, b))
 ae2(qrr, qr.resid(qr.Am, b))
})

```

---

sparseVector*Sparse Vector Construction from Nonzero Entries*

---

**Description**

User friendly construction of sparse vectors, i.e., objects inheriting from [class sparseVector](#), from indices and values of its non-zero entries.

**Usage**

```
sparseVector(x, i, length)
```

**Arguments**

|        |                                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------|
| x      | vector of the non zero entries; may be missing in which case a "nsparseVector" will be returned.                            |
| i      | integer vector (of the same length as x) specifying the indices of the non-zero (or non-TRUE) entries of the sparse vector. |
| length | length of the sparse vector.                                                                                                |

**Details**

zero entries in x are dropped automatically, analogously as [drop0\(\)](#) acts on sparse matrices.

**Value**

a sparse vector, i.e., inheriting from [class sparseVector](#).

**Author(s)**

Martin Maechler

**See Also**

[sparseMatrix\(\)](#) constructor for sparse matrices; the class [sparseVector](#).

**Examples**

```
str(sv <- sparseVector(x = 1:10, i = sample(999, 10), length=1000))

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
ss <- as(sx, "sparseVector")
stopifnot(identical(ss,
 sparseVector(x = c(2, -1, -2, 3, 1, -3, 5, 3.2),
 i = c(15L, 10:9, 3L,12L,8L,18L, 4L), length = 20L)))

(ns <- sparseVector(i= c(7, 3, 2), length = 10))
stopifnot(identical(ns,
 new("nsparseVector", length = 10, i = c(2, 3, 7))))
```

---

sparseVector-class      *Sparse Vector Classes*

---

**Description**

Sparse Vector Classes: The virtual mother class "sparseVector" has the five actual daughter classes "dsparseVector", "isparseVector", "lsparseVector", "nsparseVector", and "zsparseVector", where we've mainly implemented methods for the d\*, l\* and n\* ones.

**Slots**

- length:** class "numeric" - the **length** of the sparse vector. Note that "numeric" can be considerably larger than the maximal "integer", `.Machine$integer.max`, on purpose.
- i:** class "numeric" - the (1-based) indices of the non-zero entries. Must *not* be NA and strictly sorted increasingly.  
Note that "integer" is "part of" "numeric", and can (and often will) be used for non-huge sparseVectors.
- x:** (for all but "nsparseVector"): the non-zero entries. This is of class "numeric" for class "dsparseVector", "logical" for class "lsparseVector", etc.

**Methods**

- length** signature(`x = "sparseVector"`): simply extracts the length slot.
- show** signature(`object = "sparseVector"`): The **show** method for sparse vectors prints "*structural*" zeroes as "." using the non-exported `prSpVector` function which allows further customization such as replacing "." by " " (blank).  
Note that **options**(`max.print`) will influence how many entries of large sparse vectors are printed at all.
- as.vector** signature(`x = "sparseVector"`, `mode = "character"`) coerces sparse vectors to "regular", i.e., atomic vectors. This is the same as `as(x, "vector")`.
- as** ...: see coerce below
- coerce** signature(`from = "sparseVector"`, `to = "sparseMatrix"`), and  
**coerce** signature(`from = "sparseMatrix"`, `to = "sparseVector"`), etc: coercions to and from sparse matrices (**sparseMatrix**) are provided and work analogously as in standard R, i.e., a vector is coerced to a 1-column matrix.
- dim<-** signature(`x = "sparseVector"`, `value = "integer"`) coerces a sparse vector to a sparse Matrix, i.e., an object inheriting from **sparseMatrix**, of the appropriate dimension.
- head** signature(`x = "sparseVector"`): as with R's (package **util**) **head**, `head(x, n)` (for  $n \geq 1$ ) is equivalent to `x[1:n]`, but here can be much more efficient, see the example.
- tail** signature(`x = "sparseVector"`): analogous to **head**, see above.
- toeplitz** signature(`x = "sparseVector"`): as **toeplitz**(`x`), produce the  $n \times n$  Toeplitz matrix from `x`, where  $n = \text{length}(x)$ .
- rep** signature(`x = "sparseVector"`) repeat `x`, with the same argument list (`x`, `times`, `length.out`, `each`, ...) as the default method for `rep()`.
- which** signature(`x = "nsparseVector"`) and  
**which** signature(`x = "lsparseVector"`) return the indices of the non-zero entries (which is trivial for sparse vectors).

**Ops** signature(e1 = "sparseVector", e2 = "\*"): define arithmetic, compare and logic operations, (see [Ops](#)).

**Summary** signature(x = "sparseVector"): define all the [Summary](#) methods.

**is.na, is.finite, is.infinite** (x = "sparseVector"), and

**is.na, is.finite, is.infinite** (x = "nsparseVector"): return [logical](#) or "nsparseVector" of the same length as x, indicating if/where x is [NA](#) (or NaN), finite or infinite, entirely analogously to the corresponding base R functions.

**zapsmall** signature(x = "sparseVectors"): typically used for numeric sparse vector: [round\(\)](#) entries such that (relatively) very small entries become zero exactly.

c. sparseVector() is an S3 method for all "sparseVector"s, but automatic dispatch only happens for the first argument, so it is useful also as regular R function, see the examples.

## See Also

[sparseVector\(\)](#) for friendly construction of sparse vectors (apart from `as(*, "sparseVector")`).

## Examples

```
getClass("sparseVector")
getClass("dsparseVector")

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
(ss <- as(sx, "sparseVector"))

ix <- as.integer(round(sx))
(is <- as(ix, "sparseVector")) ## an "isparsedVector" (!)
(ns <- sparseVector(i= c(7, 3, 2), length = 10)) # "nsparseVector"
rep() works too:
(ri <- rep(is, length.out= 25))

Using `dim<-` as in base R :
r <- ss
dim(r) <- c(4,5) # becomes a sparse Matrix:
r
or coercion (as as.matrix() in base R):
as(ss, "Matrix")
stopifnot(all(ss == print(as(ss, "CsparseMatrix"))))

currently has "non-structural" FALSE -- printing as ":"
(lis <- is & FALSE)
(nn <- is[is == 0]) # all "structural" FALSE

NA-case
sN <- sx; sN[4] <- NA
(svN <- as(sN, "sparseVector"))

v <- as(c(0,0,3, 3.2, rep(0,9),-3,0,-1, rep(0,20),5,0),
 "sparseVector")
v <- rep(rep(v, 50), 5000)
set.seed(1); v[sample(v@i, 1e6)] <- 0
str(v)
system.time(for(i in 1:4) hv <- head(v, 1e6))
user system elapsed
0.033 0.000 0.032
```

```

system.time(for(i in 1:4) h2 <- v[1:1e6])
user system elapsed
1.317 0.000 1.319

stopifnot(identical(hv, h2),
 identical(is | FALSE, is != 0),
 validObject(svN), validObject(lis), as.logical(is.na(svN[4])),
 identical(is^2 > 0, is & TRUE),
 all(!lis), !any(lis), length(nn@i) == 0, !any(nn), all(!nn),
 sum(lis) == 0, !prod(lis), range(lis) == c(0,0))

create and use the t(.) method:
t(x20 <- sparseVector(c(9,3:1), i=c(1:2,4,7), length=20))
(T20 <- toeplitz(x20))
stopifnot(is(T20, "symmetricMatrix"), is(T20, "sparseMatrix"),
 identical(unname(as.matrix(T20)),
 toeplitz(as.vector(x20))))

c() method for "sparseVector" - also available as regular function
(c1 <- c(x20, 0,0,0, -10*x20))
(c2 <- c(ns, is, FALSE))
(c3 <- c(ns, !ns, TRUE, NA, FALSE))
(c4 <- c(ns, rev(ns)))
here, c() would produce a list {not dispatching to c.sparseVector()}
(c5 <- c.sparseVector(0,0, x20))

checking (consistency)
.v <- as.vector
.s <- function(v) as(v, "sparseVector")
stopifnot(exprs = {
 all.equal(c1, .s(c(.v(x20), 0,0,0, -10*.v(x20))), tol = 0)
 all.equal(c2, .s(c(.v(ns), .v(is), FALSE)), tol = 0)
 all.equal(c3, .s(c(.v(ns), !.v(ns), TRUE, NA, FALSE)), tol = 0)
 all.equal(c4, .s(c(.v(ns), rev(.v(ns)))), tol = 0,
 check.class = FALSE)
 all.equal(c5, .s(c(0,0, .v(x20))), tol = 0)
})

```

---

spMatrix

---

*Sparse Matrix Constructor From Triplet*

---

## Description

User friendly construction of a sparse matrix (inheriting from class [TsparseMatrix](#)) from the triplet representation.

This is much less flexible than [sparseMatrix\(\)](#) and hence somewhat *deprecated*.

## Usage

```
spMatrix(nrow, ncol, i = integer(0L), j = integer(0L), x = double(0L))
```

**Arguments**

|            |                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------|
| nrow, ncol | integers specifying the desired number of rows and columns.                                                      |
| i, j       | integer vectors of the same length specifying the locations of the non-zero (or non-TRUE) entries of the matrix. |
| x          | atomic vector of the same length as i and j, specifying the values of the non-zero entries.                      |

**Value**

A sparse matrix in triplet form, as an R object inheriting from both [TsparseMatrix](#) and [generalMatrix](#).

The matrix  $M$  will have  $M[i[k], j[k]] = x[k]$ , for  $k = 1, 2, \dots, n$ , where  $n = \text{length}(i)$  and  $M[i', j'] = 0$  for all other pairs  $(i', j')$ .

**See Also**

[Matrix](#)(\*, sparse=TRUE) for the more usual constructor of such matrices. Then, [sparseMatrix](#) is more general and flexible than [spMatrix](#)() and by default returns a [CsparseMatrix](#) which is often slightly more desirable. Further, [bdiag](#) and [Diagonal](#) for (block-)diagonal matrix constructors.

Consider [TsparseMatrix](#) and similar class definition help files.

**Examples**

```
simple example
A <- spMatrix(10,20, i = c(1,3:8),
 j = c(2,9,6:10),
 x = 7 * (1:7))

A # a "dgTMatrix"
summary(A)
str(A) # note that *internally* 0-based indices (i,j) are used

L <- spMatrix(9, 30, i = rep(1:9, 3), 1:27,
 (1:27) %% 4 != 1)
L # an "lgTMatrix"

A simplified predecessor of Matrix' rsparsematrix() function :

rSpMatrix <- function(nrow, ncol, nnz,
 rand.x = function(n) round(rnorm(nnz), 2))
{
 ## Purpose: random sparse matrix
 ## -----
 ## Arguments: (nrow,ncol): dimension
 ## nnz : number of non-zero entries
 ## rand.x: random number generator for 'x' slot
 ## -----
 ## Author: Martin Maechler, Date: 14.-16. May 2007
 stopifnot((nnz <- as.integer(nnz)) >= 0,
 nrow >= 0, ncol >= 0, nnz <= nrow * ncol)
 spMatrix(nrow, ncol,
 i = sample(nrow, nnz, replace = TRUE),
 j = sample(ncol, nnz, replace = TRUE),
 x = rand.x(nnz))
}
```

```

}

M1 <- rSpMatrix(100000, 20, nnz = 200)
summary(M1)

```

subassign-methods

*Methods for "[<-" - Assigning to Subsets of 'Matrix'*

## Description

Methods for "[<-", i.e., extraction or subsetting mostly of matrices, in package **Matrix**.

**Note:** Contrary to standard `matrix` assignment in base R, in `x[. .] <- val` it is typically an **error** (see `stop`) when the `type` or `class` of `val` would require the class of `x` to be changed, e.g., when `x` is logical, say `"lsparseMatrix"`, and `val` is numeric. In other cases, e.g., when `x` is a `"nsparseMatrix"` and `val` is not TRUE or FALSE, a warning is signalled, and `val` is “interpreted” as `logical`, and (logical) `NA` is interpreted as TRUE.

## Methods

There are *many many* more than these:

`x = "Matrix", i = "missing", j = "missing", value = "ANY"` is currently a simple fallback method implementation which ensures “readable” error messages.

`x = "Matrix", i = "ANY", j = "ANY", value = "ANY"` currently gives an error

`x = "denseMatrix", i = "index", j = "missing", value = "numeric" ...`

`x = "denseMatrix", i = "index", j = "index", value = "numeric" ...`

`x = "denseMatrix", i = "missing", j = "index", value = "numeric" ...`

## See Also

[\[-methods](#) for subsetting "Matrix" objects; the [index](#) class; [Extract](#) about the standard subset assignment (and extraction).

## Examples

```

set.seed(101)
(a <- m <- Matrix(round(rnorm(7*4),2), nrow = 7))

a[] <- 2.2 # <- replaces every entry
a
as do these:
a[,] <- 3 ; a[TRUE,] <- 4

m[2, 3] <- 3.14 # simple number
m[3, 3:4] <- 3:4 # simple numeric of length 2

sub matrix assignment:
m[-(4:7), 3:4] <- cbind(1,2:4) #-> upper right corner of 'm'
m[3:5, 2:3] <- 0
m[6:7, 1:2] <- Diagonal(2)
m

```

```
rows or columns only:
m[1,] <- 10
m[,2] <- 1:7
m[-(1:6),] <- 3:0 # not the first 6 rows, i.e. only the 7th
as(m, "sparseMatrix")
```

subscript-methods

*Methods for "[": Extraction or Subsetting in Package 'Matrix'*

## Description

Methods for "[", i.e., extraction or subsetting mostly of matrices, in package **Matrix**.

## Methods

There are more than these:

```
x = "Matrix", i = "missing", j = "missing", drop = "ANY" ...
x = "Matrix", i = "numeric", j = "missing", drop = "missing" ...
x = "Matrix", i = "missing", j = "numeric", drop = "missing" ...
x = "dsparseMatrix", i = "missing", j = "numeric", drop = "logical" ...
x = "dsparseMatrix", i = "numeric", j = "missing", drop = "logical" ...
x = "dsparseMatrix", i = "numeric", j = "numeric", drop = "logical" ...
```

## See Also

[\[<--methods](#) for subassignment to "Matrix" objects. [Extract](#) about the standard extraction.

## Examples

```
str(m <- Matrix(round(rnorm(7*4),2), nrow = 7))
stopifnot(identical(m, m[]))
m[2, 3] # simple number
m[2, 3:4] # simple numeric of length 2

symmetricMatrix-class *Virtual Class of Symmetric Matrices in Package Matrix*

---

## Description

The virtual class of symmetric matrices, "symmetricMatrix", from the package **Matrix** contains numeric and logical, dense and sparse matrices, e.g., see the examples with the "actual" subclasses.

The main use is in methods (and C functions) that can deal with all symmetric matrices, and in `as(*, "symmetricMatrix")`.

## Slots

`Dim`, `Dimnames` inherited from virtual class [Matrix](#). See comments below about symmetry of `Dimnames`.

`factors` a list of [MatrixFactorization](#) objects caching factorizations of the matrix. Typically, it is initialized as an empty list and updated "automagically" whenever a factorization is computed.

`uplo` a character string, either "U" or "L" indicating that only entries in the upper or lower triangle are referenced.

## Extends

Class "Matrix", directly.

## Methods

**dimnames** `signature(object = "symmetricMatrix")`: returns *symmetric dimnames*, even when the `Dimnames` slot only has row or column names. This allows to save storage for large (typically sparse) symmetric matrices.

**isSymmetric** `signature(object = "symmetricMatrix")`: returns TRUE trivially.

There's a C function `symmetricMatrix_validate()` called by the internal validity checking functions, and also from `getValidity(getClass("symmetricMatrix"))`.

## Validity and `dimnames`

The validity checks do not require a symmetric `Dimnames` slot, so it can be `list(NULL, <character>)`, e.g., for efficiency. However, `dimnames()` and other functions and methods should behave as if the `dimnames` were symmetric, i.e., with both list components identical.

## See Also

[isSymmetric](#) which has efficient methods ([isSymmetric-methods](#)) for the **Matrix** classes. Classes [triangularMatrix](#), and, e.g., [dsyMatrix](#) for numeric *dense* matrices, or [lsMatrix](#) for a logical *sparse* matrix class.

## Examples

```
An example about the symmetric Dimnames:
sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5, dims = c(7,7),
 symmetric=TRUE, dimnames = list(NULL, letters[1:7]))
sy # shows symmetrical dimnames
sy@Dimnames # internally only one part is stored
dimnames(sy) # both parts - as sy *is* symmetrical

showClass("symmetricMatrix")

The names of direct subclasses:
scl <- getClass("symmetricMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

Methods -- applicaple to all subclasses above:
showMethods(classes = "symmetricMatrix")
```

---

symmpart-methods

*Symmetric Part and Skew(symmetric) Part of a Matrix*

---

## Description

`symmpart(x)` computes the symmetric part  $(x + t(x))/2$  and `skewpart(x)` the skew symmetric part  $(x - t(x))/2$  of a square matrix `x`, more efficiently for specific Matrix classes.

Note that `x == symmpart(x) + skewpart(x)` for all square matrices – apart from extraneous NA values in the RHS.

## Usage

```
symmpart(x)
skewpart(x)
```

## Arguments

`x` a *square* matrix; either “traditional” of class “matrix”, or typically, inheriting from the [Matrix](#) class.

## Details

These are generic functions with several methods for different matrix classes, use e.g., [showMethods\(symmpart\)](#) to see them.

If the row and column names differ, the result will use the column names unless they are (partly) NULL where the row names are non-NULL (see also the examples).

## Value

`symmpart(x)` returns a symmetric matrix, inheriting from [symmetricMatrix](#) or [diagonalMatrix](#) if `x` inherits from [Matrix](#).

`skewpart(x)` returns a skew-symmetric matrix, inheriting from [generalMatrix](#), [symmetricMatrix](#) or [diagonalMatrix](#) if `x` inherits from [Matrix](#).

**See Also**

[isSymmetric](#).

**Examples**

```
m <- Matrix(1:4, 2,2)
symmpart(m)
skewpart(m)

stopifnot(all(m == symmpart(m) + skewpart(m)))

dn <- dimnames(m) <- list(row = c("r1", "r2"), col = c("var.1", "var.2"))
stopifnot(all(m == symmpart(m) + skewpart(m)))
colnames(m) <- NULL
stopifnot(all(m == symmpart(m) + skewpart(m)))
dimnames(m) <- unname(dn)
stopifnot(all(m == symmpart(m) + skewpart(m)))

investigate the current methods:
showMethods(skewpart, include = TRUE)
```

---

triangularMatrix-class

*Virtual Class of Triangular Matrices in Package Matrix*

---

**Description**

The virtual class of triangular matrices, "triangularMatrix", the package **Matrix** contains *square* (`nrow == ncol`) numeric and logical, dense and sparse matrices, e.g., see the examples. A main use of the virtual class is in methods (and C functions) that can deal with all triangular matrices.

**Slots**

**uplo:** String (of class "character"). Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** String (of class "character"). Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The diagonal elements are not accessed internally when diag is "U". For [denseMatrix](#) classes, they need to be allocated though, such that the length of the x slot does not depend on diag.

**Dim, Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

**Extends**

Class "Matrix", directly.

**Methods**

There's a C function `triangularMatrix_validity()` called by the internal validity checking functions.

Currently, [Schur](#), [isSymmetric](#) and `as()` (i.e. [coerce](#)) have methods with `triangularMatrix` in their signature.

**See Also**

`isTriangular()` for testing any matrix for triangularity; classes `symmetricMatrix`, and, e.g., `dtrMatrix` for numeric *dense* matrices, or `ltcMatrix` for a logical *sparse* matrix subclass of `"triangularMatrix"`.

**Examples**

```
showClass("triangularMatrix")

The names of direct subclasses:
scl <- getClass("triangularMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

(m <- matrix(c(5,1,0,3), 2))
as(m, "triangularMatrix")
```

---

TsparseMatrix-class      *Class "TsparseMatrix" of Sparse Matrices in Triplet Form*

---

**Description**

The `"TsparseMatrix"` class is the virtual class of all sparse matrices coded in triplet form. Since it is a virtual class, no objects may be created from it. See `showClass("TsparseMatrix")` for its subclasses.

**Slots**

**Dim, Dimnames:** from the `"Matrix"` class,

**i:** Object of class `"integer"` - the row indices of non-zero entries *in 0-base*, i.e., must be in  $0:(nrow(.)-1)$ .

**j:** Object of class `"integer"` - the column indices of non-zero entries. Must be the same length as slot `i` and *0-based* as well, i.e., in  $0:(ncol(.)-1)$ . For numeric `Tsparse` matrices,  $(i, j)$  pairs can occur more than once, see `dgTMatrix`.

**Extends**

Class `"sparseMatrix"`, directly. Class `"Matrix"`, by class `"sparseMatrix"`.

**Methods**

Extraction (`"["`) methods, see [\[-methods](#).

**Note**

Most operations with sparse matrices are performed using the compressed, column-oriented or `CsparseMatrix` representation. The triplet representation is convenient for creating a sparse matrix or for reading and writing such matrices. Once it is created, however, the matrix is generally coerced to a `CsparseMatrix` for further operations.

Note that all `new()`, `spMatrix` and `sparseMatrix(*, repr="T")` constructors for `"TsparseMatrix"` classes implicitly add (i.e., “sum up”)  $x_k$ ’s that belong to identical  $(i_k, j_k)$  pairs, see, the example below, or also `dgTMatrix`.

For convenience, methods for some operations such as `%%` and `crossprod` are defined for `TsparseMatrix` objects. These methods simply coerce the `TsparseMatrix` object to a `CsparseMatrix` object then perform the operation.

### See Also

its superclass, `sparseMatrix`, and the `dgTMatrix` class, for the links to other classes.

### Examples

```
showClass("TsparseMatrix")
or just the subclasses' names
names(getClass("TsparseMatrix")@subclasses)

T3 <- spMatrix(3,4, i=c(1,3:1), j=c(2,4:2), x=1:4)
T3 # only 3 non-zero entries, 5 = 1+4 !
```

---

unpackedMatrix-class    *Virtual Class "unpackedMatrix" of Unpacked Dense Matrices*

---

### Description

Class "unpackedMatrix" is the *virtual* class of dense matrices in "unpacked" format, storing all  $m \times n$  elements of an  $m$ -by- $n$  matrix. It is used to define common methods for efficient sub-setting, transposing, etc. of its *proper* subclasses: currently "[dln]geMatrix" (unpacked general), "[dln]syMatrix" (unpacked symmetric), "[dln]trMatrix" (unpacked triangular), and subclasses of these, such as "`dpoMatrix`".

### Slots

`Dim`, `Dimnames`: as all `Matrix` objects.

### Extends

Class "`denseMatrix`", directly. Class "`Matrix`", by class "`denseMatrix`", distance 2.

### Methods

```
pack signature(x = "unpackedMatrix"): ...
unpack signature(x = "unpackedMatrix"): ...
isSymmetric signature(object = "unpackedMatrix"): ...
isTriangular signature(object = "unpackedMatrix"): ...
isDiagonal signature(object = "unpackedMatrix"): ...
t signature(x = "unpackedMatrix"): ...
diag signature(x = "unpackedMatrix"): ...
diag<- signature(x = "unpackedMatrix"): ...
```

### Author(s)

Mikael Jagan

**See Also**

`pack` and `unpack`; its virtual "complement" "`packedMatrix`"; its proper subclasses "`dsyMatrix`", "`ltrMatrix`", etc.

**Examples**

```
showClass("unpackedMatrix")
showMethods(classes = "unpackedMatrix")
```

updown-methods

*Updating and Downdating Sparse Cholesky Factorizations***Description**

Computes a rank- $k$  update or downdate of a sparse Cholesky factorization

$$P_1 A P_1' = L_1 D L_1' = L L'$$

which for some  $k$ -column matrix  $C$  is the factorization

$$P_1 (A + s C C') P_1' = \tilde{L}_1 \tilde{D} \tilde{L}_1' = \tilde{L} \tilde{L}'$$

Here,  $s = 1$  for an update and  $s = -1$  for a downdate.

**Usage**

```
updown(update, C, L)
```

**Arguments**

|        |                                                                                                                      |
|--------|----------------------------------------------------------------------------------------------------------------------|
| update | a logical (TRUE or FALSE) or character ("+" or "-") indicating if L should be updated (or otherwise downdated).      |
| C      | a <a href="#">finite</a> matrix or <code>Matrix</code> such that <code>tcrossprod(C)</code> has the dimensions of L. |
| L      | an object of class <code>dCHMsimpl</code> or <code>dCHMsupper</code> specifying a sparse Cholesky factorization.     |

**Value**

A sparse Cholesky factorization with dimensions matching L, typically of class `dCHMsimpl`.

**Author(s)**

Initial implementation by Nicholas Nagle, University of Tennessee.

**References**

Davis, T. A., Hager, W. W. (2001). Multiple-rank modifications of a sparse Cholesky factorization. *SIAM Journal on Matrix Analysis and Applications*, 22(4), 997-1013. doi:10.1137/S0895479899357346

**See Also**

Classes [dCHMsimpl](#) and [dCHMsuper](#) and their methods, notably for generic function [update](#), which is *not* equivalent to `updown(update = TRUE)`.

Generic function [Cholesky](#).

**Examples**

```
m <- sparseMatrix(i = c(3, 1, 3:2, 2:1), p = c(0:2, 4, 4, 6), x = 1:6,
 dimnames = list(LETTERS[1:3], letters[1:5]))
uc0 <- Cholesky(A <- crossprod(m) + Diagonal(5))
uc1 <- updown("+", Diagonal(5, 1), uc0)
uc2 <- updown("-", Diagonal(5, 1), uc1)
stopifnot(all.equal(uc0, uc2))
```

---

USCounties

---

*Contiguity Matrix of U.S. Counties*

---

**Description**

This matrix gives the contiguities of 3111 U.S. counties, using the queen criterion of at least one shared vertex or edge.

**Usage**

```
data(USCounties)
```

**Format**

A  $3111 \times 3111$  sparse, symmetric matrix of class [dsCMatrix](#), with 9101 nonzero entries.

**Source**

GAL lattice file ‘usc\_q.GAL’ (retrieved in 2008 from ‘<http://sal.uiuc.edu/weights/zips/usc.zip>’ with permission from Luc Anselin for use and distribution) was read into R using function `read.gal` from package [spdep](#).

Neighbour lists were augmented with row-standardized (and then symmetrized) spatial weights, using functions `nb2listw` and `similar.listw` from packages [spdep](#) and [spatialreg](#). The resulting listw object was coerced to class [dsTMatrix](#) using `as_dsTMatrix_listw` from [spatialreg](#), and subsequently to class [dsCMatrix](#).

**References**

Ord, J. K. (1975). Estimation methods for models of spatial interaction. *Journal of the American Statistical Association*, 70(349), 120-126. doi:[10.2307/2285387](https://doi.org/10.2307/2285387)

## Examples

```
data(USCounties, package = "Matrix")
(n <- ncol(USCounties))
I <- .symDiagonal(n)

set.seed(1)
r <- 50L
rho <- 1 / runif(r, 0, 0.5)

system.time(MJ0 <- sapply(rho, function(mult)
 determinant(USCounties + mult * I, logarithm = TRUE)$modulus))

Can be done faster by updating the Cholesky factor:

C1 <- Cholesky(USCounties, Imult = 2)
system.time(MJ1 <- sapply(rho, function(mult)
 determinant(update(C1, USCounties, mult), sqrt = FALSE)$modulus))
stopifnot(all.equal(MJ0, MJ1))

C2 <- Cholesky(USCounties, super = TRUE, Imult = 2)
system.time(MJ2 <- sapply(rho, function(mult)
 determinant(update(C2, USCounties, mult), sqrt = FALSE)$modulus))
stopifnot(all.equal(MJ0, MJ2))
```

wrlld\_1deg

*Contiguity Matrix of World One-Degree Grid Cells*

## Description

This matrix gives the contiguities of 15260 one-degree grid cells of world land areas, using a criterion based on the great-circle distance between centers.

## Usage

```
data(wrlld_1deg)
```

## Format

A  $15260 \times 15260$  sparse, symmetric matrix of class `dsCMatrix`, with 55973 nonzero entries.

## Source

Shoreline data were read into R from the GSHHS database using function `Rgshhs` from package **maptools**. Antarctica was excluded. An approximately one-degree grid was generated using function `Sobj_SpatialGrid`, also from **maptools**. Grid cells with centers on land were identified using the `over` method for classes `SpatialPolygons` and `SpatialGrid`, defined in package **sp**. Neighbours of these were identified by passing the resulting `SpatialPixels` object to function `dnearneigh` from package **spdep**, using as a cut-off a great-circle distance of  $\sqrt{2}$  kilometers between centers.

Neighbour lists were augmented with row-standardized (and then symmetrized) spatial weights, using functions `nb2listw` and `similar.listw` from packages **spdep** and **spatialreg**. The resulting `listw` object was coerced to class `dsTMatrix` using `as_dsTMatrix_listw` from **spatialreg**, and subsequently to class `dsCMatrix`.

## References

Ord, J. K. (1975). Estimation methods for models of spatial interaction. *Journal of the American Statistical Association*, 70(349), 120-126. doi:10.2307/2285387

## Examples

```
data(wrld_1deg, package = "Matrix")
(n <- ncol(wrld_1deg))
I <- .symDiagonal(n)

doExtras <- interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA"))
set.seed(1)
r <- if(doExtras) 20L else 3L
rho <- 1 / runif(r, 0, 0.5)

system.time(MJ0 <- sapply(rho, function(mult)
 determinant(wrld_1deg + mult * I, logarithm = TRUE)$modulus))

Can be done faster by updating the Cholesky factor:

C1 <- Cholesky(wrld_1deg, Imult = 2)
system.time(MJ1 <- sapply(rho, function(mult)
 determinant(update(C1, wrld_1deg, mult), sqrt = FALSE)$modulus))
stopifnot(all.equal(MJ0, MJ1))

C2 <- Cholesky(wrld_1deg, super = TRUE, Imult = 2)
system.time(MJ2 <- sapply(rho, function(mult)
 determinant(update(C2, wrld_1deg, mult), sqrt = FALSE)$modulus))
stopifnot(all.equal(MJ0, MJ2))
```

## Chapter 18

# The boot package

---

abc.ci

*Nonparametric ABC Confidence Intervals*

---

### Description

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

### Usage

```
abc.ci(data, statistic, index=1, strata=rep(1, n), conf=0.95,
 eps=0.001/n, ...)
```

### Arguments

|           |                                                                                                                                                                                                                                                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data      | A data set expressed as a vector, matrix or data frame.                                                                                                                                                                                                                                                                                      |
| statistic | A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to statistic will be normalized to sum to 1 within each stratum. Any other arguments should be passed to abc.ci as part of the ...{} argument. |
| index     | If statistic returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.                                                                                                                                                                                                     |
| strata    | A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.                                                                                                                                                                                            |
| conf      | A scalar or vector containing the confidence level(s) of the required interval(s).                                                                                                                                                                                                                                                           |
| eps       | The value of epsilon to be used for the numerical differentiation.                                                                                                                                                                                                                                                                           |
| ...       | Any other arguments for statistic. These will be passed unchanged to statistic each time it is called within abc.ci.                                                                                                                                                                                                                         |

## Details

This function is based on the function `abnnon` written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is  $2 \cdot n + 2 \cdot \text{length}(\text{conf})$  where  $n$  is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

## Value

A `length(conf)` by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

|------|-------------------------------|
| acme | <i>Monthly Excess Returns</i> |
|------|-------------------------------|

---

### Description

The acme data frame has 60 rows and 3 columns.

The excess return for the Acme Cleveland Corporation are recorded along with those for all stocks listed on the New York and American Stock Exchanges were recorded over a five year period. These excess returns are relative to the return on a risk-less investment such a U.S. Treasury bills.

### Usage

acme

### Format

This data frame contains the following columns:

month A character string representing the month of the observation.

market The excess return of the market as a whole.

acme The excess return for the Acme Cleveland Corporation.

### Source

The data were obtained from

|------|-----------------------------------------------------|
| aids | <i>Delay in AIDS Reporting in England and Wales</i> |
|------|-----------------------------------------------------|

---

### Description

The aids data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.

### Usage

aids

**Format**

This data frame contains the following columns:

year The year of the diagnosis.

quarter The quarter of the year in which diagnosis was made.

delay The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of delay is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).

dud An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.

time The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.

y The number of AIDS cases reported.

**Source**

The data were obtained from

aircondit

*Failures of Air-conditioning Equipment*

---

**Description**

Proschan (1963) reported on the times between failures of the air-conditioning equipment in 10 Boeing 720 aircraft. The aircondit data frame contains the intervals for the ninth aircraft while aircondit7 contains those for the seventh aircraft.

Both data frames have just one column. Note that the data have been sorted into increasing order.

**Usage**

aircondit

**Format**

The data frames contain the following column:

hours The time interval in hours between successive failures of the air-conditioning equipment

**Source**

The data were taken from

Cox, D.R. and Snell, E.J. (1981) *Applied Statistics: Principles and Examples*. Chapman and Hall.

amis

*Car Speeding and Warning Signs*

---

## Description

The amis data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

## Usage

amis

## Format

This data frame contains the following columns:

speed Speeds of cars (in miles per hour).

period A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.

warning A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.

pair A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

## Source

The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

aml

*Remission Times for Acute Myelogenous Leukaemia***Description**

The aml data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

**Usage**

aml

**Format**

This data frame contains the following columns:

time The length of the complete remission (in weeks).

cens An indicator of right censoring. 1 indicates that the patient had a relapse and so time is the length of the remission. 0 indicates that the patient had left the study or was still in remission in October 1974, that is the length of remission is right-censored.

group The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

**Note**

Package **survival** also has a dataset aml. It is the same data with different names and with group replaced by a factor x.

**Source**

The data were obtained from

Miller, R.G. (1981) *Survival Analysis*. John Wiley.

beaver*Beaver Body Temperature Data*

---

### Description

The beaver data frame has 100 rows and 4 columns. It is a multivariate time series of class "ts" and also inherits from class "data.frame".

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radio transmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

### Usage

```
beaver
```

### Format

This data frame contains the following columns:

`day` The day number. The data includes only data from day 307 and early 308.

`time` The time of day formatted as hour-minute.

`temp` The body temperature in degrees Celsius.

`activ` The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.

### Source

The data were obtained from

Reynolds, P.S. (1994) Time-series analyses of beaver body temperatures. In *Case Studies in Biometry*. N. Lange, L. Ryan, L. Billard, D. Brillinger, L. Conquest and J. Greenhouse (editors), 211–228. John Wiley.

|---------|----------------------------------|
| bigcity | <i>Population of U.S. Cities</i> |
|---------|----------------------------------|

---

### Description

The bigcity data frame has 49 rows and 2 columns.

The city data frame has 10 rows and 2 columns.

The measurements are the population (in 1000's) of 49 U.S. cities in 1920 and 1930. The 49 cities are a random sample taken from the 196 largest cities in 1920. The city data frame consists of the first 10 observations in bigcity.

### Usage

```
bigcity
```

### Format

This data frame contains the following columns:

u The 1920 population.

x The 1930 population.

|      |                             |
|------|-----------------------------|
| boot | <i>Bootstrap Resampling</i> |
|------|-----------------------------|

---

### Description

Generate R bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used: this is specified by including a vector of strata in the call to boot. Importance resampling weights may be specified.

### Usage

```
boot(data, statistic, R, sim = "ordinary", stype = c("i", "f", "w"),
 strata = rep(1,n), L = NULL, m = 0, weights = NULL,
 ran.gen = function(d, p) d, mle = NULL, simple = FALSE, ...,
 parallel = c("no", "multicore", "snow"),
 ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>statistic</code> | A function which when applied to data returns a vector containing the statistic(s) of interest. When <code>sim = "parametric"</code> , the first argument to <code>statistic</code> must be the data. For each replicate a simulated dataset returned by <code>ran.gen</code> will be passed. In all other cases <code>statistic</code> must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to <code>statistic</code> through the <code>...</code> argument. |
| <code>R</code>         | The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case <code>R</code> would be a vector of integers where each component gives the number of resamples from each of the rows of weights.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>sim</code>       | A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be "ordinary" or "balanced" in this case.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>stype</code>     | A character string indicating what the second argument of <code>statistic</code> represents. Possible values of <code>stype</code> are "i" (indices - the default), "f" (frequencies), or "w" (weights). Not used for <code>sim = "parametric"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>strata</code>    | An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when <code>sim = "parametric"</code> . When <code>strata</code> is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>L</code>         | Vector of influence values evaluated at the observations. This is used only when <code>sim</code> is "antithetic". If not supplied, they are calculated through a call to <code>empinf</code> . This will use the infinitesimal jackknife provided that <code>stype</code> is "w", otherwise the usual jackknife is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>m</code>         | The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when <code>sim</code> is "ordinary". <code>m</code> will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of <code>statistic</code> , which should also take an argument giving the vector of indices of the errors to be used for the predictions.                                                                                                                                                                         |
| <code>weights</code>   | Vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in data. When simulation from more than one set of weights is required, <code>weights</code> should be a matrix where each row of the matrix is one set of importance weights. If <code>weights</code> is a matrix then <code>R</code> must be a vector of length <code>nrow(weights)</code> . This parameter is ignored if <code>sim</code> is not "ordinary" or "balanced".                                                                                                                                                                                                                                                                                                               |
| <code>ran.gen</code>   | This function is used only when <code>sim = "parametric"</code> when it describes how random values are to be generated. It should be a function of two arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

The first argument should be the observed data and the second argument consists of any other information needed (e.g. parameter estimates). The second argument may be a list, allowing any number of items to be passed to `ran.gen`. The returned value should be a simulated data set of the same form as the observed data which will be passed to `statistic` to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If `ran.gen` is not specified, the default is a function which returns the original data in which case all simulation should be included as part of `statistic`. Use of `sim = "parametric"` with a suitable `ran.gen` allows the user to implement any types of nonparametric resampling which are not supported directly.

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mle</code>      | The second argument to be passed to <code>ran.gen</code> . Typically these will be maximum likelihood estimates of the parameters. For efficiency <code>mle</code> is often a list containing all of the objects needed by <code>ran.gen</code> which can be calculated using the original data set only.                                                                                                                                                     |
| <code>simple</code>   | logical, only allowed to be TRUE for <code>sim = "ordinary"</code> , <code>stype = "i"</code> , <code>n = 0</code> (otherwise ignored with a warning). By default a <code>n</code> by <code>R</code> index array is created: this can be large and if <code>simple = TRUE</code> this is avoided by sampling separately for each replication, which is slower but uses less memory.                                                                           |
| <code>...</code>      | Other named arguments for <code>statistic</code> which are passed unchanged each time it is called. Any such arguments to <code>statistic</code> should follow the arguments which <code>statistic</code> is required to have for the simulation. Beware of partial matching to arguments of <code>boot</code> listed above, and that arguments named <code>X</code> and <code>FUN</code> cause conflicts in some versions of <b>boot</b> (but not this one). |
| <code>parallel</code> | The type of parallel operation to be used (if any). If missing, the default is taken from the option " <code>boot.parallel</code> " (and if that is not set, " <code>no</code> ").                                                                                                                                                                                                                                                                            |
| <code>ncpus</code>    | integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.                                                                                                                                                                                                                                                                                                                                |
| <code>cl</code>       | An optional <b>parallel</b> or <b>snow</b> cluster for use if <code>parallel = "snow"</code> . If not supplied, a cluster on the local machine is created for the duration of the boot call.                                                                                                                                                                                                                                                                  |

## Details

The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. `statistic` is treated as a black box by the `boot` function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechtman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with strata. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within strata if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function `ran.gen` which will return a simulated data set from the observed data set and a set of parameter estimates specified in `mle`.

## Value

The returned value is an object of class "`boot`", containing the following components:

|                 |                                                               |
|-----------------|---------------------------------------------------------------|
| <code>t0</code> | The observed value of <code>statistic</code> applied to data. |
|-----------------|---------------------------------------------------------------|

|                        |                                                                                                                                                                                                                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t</code>         | A matrix with <code>sum(R)</code> rows each of which is a bootstrap replicate of the result of calling <code>statistic</code> .                                                                                                                                                                                                            |
| <code>R</code>         | The value of <code>R</code> as passed to <code>boot</code> .                                                                                                                                                                                                                                                                               |
| <code>data</code>      | The data as passed to <code>boot</code> .                                                                                                                                                                                                                                                                                                  |
| <code>seed</code>      | The value of <code>.Random.seed</code> when <code>boot</code> started work.                                                                                                                                                                                                                                                                |
| <code>statistic</code> | The function <code>statistic</code> as passed to <code>boot</code> .                                                                                                                                                                                                                                                                       |
| <code>sim</code>       | Simulation type used.                                                                                                                                                                                                                                                                                                                      |
| <code>stype</code>     | Statistic type as passed to <code>boot</code> .                                                                                                                                                                                                                                                                                            |
| <code>call</code>      | The original call to <code>boot</code> .                                                                                                                                                                                                                                                                                                   |
| <code>strata</code>    | The strata used. This is the vector passed to <code>boot</code> , if it was supplied or a vector of ones if there were no strata. It is not returned if <code>sim</code> is "parametric".                                                                                                                                                  |
| <code>weights</code>   | The importance sampling weights as passed to <code>boot</code> or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if <code>sim</code> is not one of "ordinary" or "balanced".                                                                                                  |
| <code>pred.i</code>    | If predictions are required ( <code>m &gt; 0</code> ) this is the matrix of indices at which predictions were calculated as they were passed to <code>statistic</code> . Omitted if <code>m</code> is 0 or <code>sim</code> is not "ordinary".                                                                                             |
| <code>L</code>         | The influence values used when <code>sim</code> is "antithetic". If no such values were specified and <code>stype</code> is not "w" then <code>L</code> is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when <code>sim</code> is not "antithetic". |
| <code>ran.gen</code>   | The random generator function used if <code>sim</code> is "parametric". This component is omitted for any other value of <code>sim</code> .                                                                                                                                                                                                |
| <code>mle</code>       | The parameter estimates passed to <code>boot</code> when <code>sim</code> is "parametric". It is omitted for all other values of <code>sim</code> .                                                                                                                                                                                        |

There are `c`, `plot` and `print` methods for this class.

### Parallel operation

When `parallel = "multicore"` is used (not available on Windows), each worker process inherits the environment of the current session, including the workspace and the loaded namespaces and attached packages (but not the random number seed: see below).

More work is needed when `parallel = "snow"` is used: the worker processes are newly created R processes, and `statistic` needs to arrange to set up the environment it needs: often a good way to do that is to make use of lexical scoping since when `statistic` is sent to the worker processes its enclosing environment is also sent. (E.g. see the example for [jack.after.boot](#) where ancillary functions are nested inside the `statistic` function.) `parallel = "snow"` is primarily intended to be used on multi-core Windows machine where `parallel = "multicore"` is not available.

For most of the `boot` methods the resampling is done in the master process, but not if `simple = TRUE` nor `sim = "parametric"`. In those cases (or where `statistic` itself uses random numbers), more care is needed if the results need to be reproducible. Resampling is done in the worker processes by [censboot](#)(`sim = "wied"`) and by most of the schemes in [tsboot](#) (the exceptions being `sim == "fixed"` and `sim == "geom"` with the default `ran.gen`).

Where random-number generation is done in the worker processes, the default behaviour is that each worker chooses a separate seed, non-reproducibly. However, with `parallel = "multicore"` or `parallel = "snow"` using the default cluster, a second approach is used if

`RNGkind("L'Ecuyer-CMRG")` has been selected. In that approach each worker gets a different subsequence of the RNG stream based on the seed at the time the worker is spawned and so the results will be reproducible if `ncpus` is unchanged, and for `parallel = "multicore"` if `parallel::mc.reset.stream()` is called: see the examples for `mclapply`.

Note that loading the **parallel** namespace may change the random seed, so for maximum reproducibility this should be done before calling this function.

## Examples

```
Usual bootstrap of the ratio of means using the city data
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
boot(city, ratio, R = 999, stype = "w")

Stratified resampling for the difference of means. In this
example we will look at the difference of means between the final
two series in the gravity data.
diff.means <- function(d, f)
{
 n <- nrow(d)
 gp1 <- 1:table(as.numeric(d$series))[1]
 m1 <- sum(d[gp1,1] * f[gp1])/sum(f[gp1])
 m2 <- sum(d[-gp1,1] * f[-gp1])/sum(f[-gp1])
 ss1 <- sum(d[gp1,1]^2 * f[gp1]) - (m1 * m1 * sum(f[gp1]))
 ss2 <- sum(d[-gp1,1]^2 * f[-gp1]) - (m2 * m2 * sum(f[-gp1]))
 c(m1 - m2, (ss1 + ss2)/(sum(f) - 2))
}
```

```

grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
boot(grav1, diff.means, R = 999, stype = "f", strata = grav1[,2])

In this example we show the use of boot in a prediction from
regression based on the nuclear data. This example is taken
from Example 6.8 of Davison and Hinkley (1997). Notice also
that two extra arguments to 'statistic' are passed through boot.
nuke <- nuclear[, c(1, 2, 5, 7, 8, 10, 11)]
nuke.lm <- glm(log(cost) ~ date+log(cap)+ne+ct+log(cum.n)+pt, data = nuke)
nuke.diag <- glm.diag(nuke.lm)
nuke.res <- nuke.diag$res * nuke.diag$sd
nuke.res <- nuke.res - mean(nuke.res)

We set up a new data frame with the data, the standardized
residuals and the fitted values for use in the bootstrap.
nuke.data <- data.frame(nuke, resid = nuke.res, fit = fitted(nuke.lm))

Now we want a prediction of plant number 32 but at date 73.00
new.data <- data.frame(cost = 1, date = 73.00, cap = 886, ne = 0,
 ct = 0, cum.n = 11, pt = 1)
new.fit <- predict(nuke.lm, new.data)

nuke.fun <- function(dat, inds, i.pred, fit.pred, x.pred)
{
 lm.b <- glm(fit+resid[inds] ~ date+log(cap)+ne+ct+log(cum.n)+pt,
 data = dat)
 pred.b <- predict(lm.b, x.pred)
 c(coef(lm.b), pred.b - (fit.pred + dat$resid[i.pred]))
}

nuke.boot <- boot(nuke.data, nuke.fun, R = 999, m = 1,
 fit.pred = new.fit, x.pred = new.data)
The bootstrap prediction squared error would then be found by
mean(nuke.boot$t[, 8]^2)
Basic bootstrap prediction limits would be
new.fit - sort(nuke.boot$t[, 8])[c(975, 25)]

Finally a parametric bootstrap. For this example we shall look
at the air-conditioning data. In this example our aim is to test
the hypothesis that the true value of the index is 1 (i.e. that
the data come from an exponential distribution) against the
alternative that the data come from a gamma distribution with
index not equal to 1.
air.fun <- function(data) {
 ybar <- mean(data$hours)
 para <- c(log(ybar), mean(log(data$hours)))
 ll <- function(k) {
 if (k <= 0) 1e200 else lgamma(k)-k*(log(k)-1-para[1]+para[2])
 }
 khat <- nlm(ll, ybar^2/var(data$hours))$estimate
 c(ybar, khat)
}

air.rg <- function(data, mle) {
 # Function to generate random exponential variates.
 # mle will contain the mean of the original data

```

```

 out <- data
 out$hours <- rexp(nrow(out), 1/mle)
 out
 }

 air.boot <- boot(aircondit, air.fun, R = 999, sim = "parametric",
 ran.gen = air.rg, mle = mean(aircondit$hours))

 # The bootstrap p-value can then be approximated by
 sum(abs(air.boot$t[,2]-1) > abs(air.boot$t0[2]-1))/(1+air.boot$R)

```

boot.array

*Bootstrap Resampling Arrays***Description**

This function takes a bootstrap object calculated by one of the functions `boot`, `censboot`, or `tilt.boot` and returns the frequency (or index) array for the bootstrap resamples.

**Usage**

```
boot.array(boot.out, indices)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | An object of class "boot" returned by one of the generation functions for such an object.                                                                                                                                                                           |
| <code>indices</code>  | A logical argument which specifies whether to return the frequency array or the raw index array. The default is <code>indices=FALSE</code> unless <code>boot.out</code> was created by <code>tsboot</code> in which case the default is <code>indices=TRUE</code> . |

**Details**

The process by which the original index array was generated is repeated with the same value of `.Random.seed`. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.

A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by `censboot` the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of `boot` or "model" in the case of `tsboot` the array cannot be found. Note also that for post-blackened bootstraps from `tsboot` the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

**Value**

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.

Side Effects

This function temporarily resets `.Random.seed` to the value in `boot.out$seed` and then returns it to its original value at the end of the function.

Examples

```
A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R = 40, stype = "w")
boot.array(city.boot)

perm.cor <- function(d,i) cor(dx,du[i])
city.perm <- boot(city, perm.cor, R = 40, sim = "permutation")
boot.array(city.perm, indices = TRUE)
```

|         |                                                     |
|---------|-----------------------------------------------------|
| boot.ci | <i>Nonparametric Bootstrap Confidence Intervals</i> |
|---------|-----------------------------------------------------|

---

Description

This function generates 5 different types of equi-tailed two-sided nonparametric confidence intervals. These are the first order normal approximation, the basic bootstrap interval, the studentized bootstrap interval, the bootstrap percentile interval, and the adjusted bootstrap percentile (BCa) interval. All or a subset of these intervals can be generated.

Usage

```
boot.ci(boot.out, conf = 0.95, type = "all",
 index = 1:min(2,length(boot.out$t0)), var.t0 = NULL,
 var.t = NULL, t0 = NULL, t = NULL, L = NULL,
 h = function(t) t, hdot = function(t) rep(1,length(t)),
 hinv = function(t) t, ...)
```

Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | An object of class "boot" containing the output of a bootstrap calculation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>conf</code>     | A scalar or vector containing the confidence level(s) of the required interval(s).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>type</code>     | A vector of character strings representing the type of intervals required. The value should be any subset of the values <code>c("norm", "basic", "stud", "perc", "bca")</code> or simply "all" which will compute all five types of intervals.                                                                                                                                                                                                                                                                                                                                                                          |
| <code>index</code>    | This should be a vector of length 1 or 2. The first element of <code>index</code> indicates the position of the variable of interest in <code>boot.out\$t0</code> and the relevant column in <code>boot.out\$t</code> . The second element indicates the position of the variance of the variable of interest. If both <code>var.t0</code> and <code>var.t</code> are supplied then the second element of <code>index</code> (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in <code>boot.out\$t0</code> ). |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>var.t0</code> | If supplied, a value to be used as an estimate of the variance of the statistic for the normal approximation and studentized intervals. If it is not supplied and <code>length(index)</code> is 2 then <code>var.t0</code> defaults to <code>boot.out\$t0[index[2]]</code> otherwise <code>var.t0</code> is undefined. For studentized intervals <code>var.t0</code> must be defined. For the normal approximation, if <code>var.t0</code> is undefined it defaults to <code>var(t)</code> . If a transformation is supplied through the argument <code>h</code> then <code>var.t0</code> should be the variance of the untransformed statistic. |
| <code>var.t</code>  | This is a vector (of length <code>boot.out\$R</code> ) of variances of the bootstrap replicates of the variable of interest. It is used only for studentized intervals. If it is not supplied and <code>length(index)</code> is 2 then <code>var.t</code> defaults to <code>boot.out\$t[, index[2]]</code> , otherwise its value is undefined which will cause an error for studentized intervals. If a transformation is supplied through the argument <code>h</code> then <code>var.t</code> should be the variance of the untransformed bootstrap statistics.                                                                                 |
| <code>t0</code>     | The observed value of the statistic of interest. The default value is <code>boot.out\$t0[index[1]]</code> . Specification of <code>t0</code> and <code>t</code> allows the user to get intervals for a transformed statistic which may not be in the bootstrap output object. See the second example below. An alternative way of achieving this would be to supply the functions <code>h</code> , <code>hdot</code> , and <code>hinv</code> below.                                                                                                                                                                                              |
| <code>t</code>      | The bootstrap replicates of the statistic of interest. It must be a vector of length <code>boot.out\$R</code> . It is an error to supply one of <code>t0</code> or <code>t</code> but not the other. Also if studentized intervals are required and <code>t0</code> and <code>t</code> are supplied then so should be <code>var.t0</code> and <code>var.t</code> . The default value is <code>boot.out\$t[, index]</code> .                                                                                                                                                                                                                      |
| <code>L</code>      | The empirical influence values of the statistic of interest for the observed data. These are used only for BCa intervals. If a transformation is supplied through the parameter <code>h</code> then <code>L</code> should be the influence values for <code>t</code> ; the values for <code>h(t)</code> are derived from these and <code>hdot</code> within the function. If <code>L</code> is not supplied then the values are calculated using <code>empinf</code> if they are needed.                                                                                                                                                         |
| <code>h</code>      | A function defining a transformation. The intervals are calculated on the scale of <code>h(t)</code> and the inverse function <code>hinv</code> applied to the resulting intervals. It must be a function of one variable only and for a vector argument, it must return a vector of the same length, i.e. <code>h(c(t1, t2, t3))</code> should return <code>c(h(t1), h(t2), h(t3))</code> . The default is the identity function.                                                                                                                                                                                                               |
| <code>hdot</code>   | A function of one argument returning the derivative of <code>h</code> . It is a required argument if <code>h</code> is supplied and normal, studentized or BCa intervals are required. The function is used for approximating the variances of <code>h(t0)</code> and <code>h(t)</code> using the delta method, and also for finding the empirical influence values for BCa intervals. Like <code>h</code> it should be able to take a vector argument and return a vector of the same length. The default is the constant function 1.                                                                                                           |
| <code>hinv</code>   | A function, like <code>h</code> , which returns the inverse of <code>h</code> . It is used to transform the intervals calculated on the scale of <code>h(t)</code> back to the original scale. The default is the identity function. If <code>h</code> is supplied but <code>hinv</code> is not, then the intervals returned will be on the transformed scale.                                                                                                                                                                                                                                                                                   |
| <code>...</code>    | Any extra arguments that <code>boot.out\$statistic</code> is expecting. These arguments are needed only if BCa intervals are required and <code>L</code> is not supplied since in that case <code>L</code> is calculated through a call to <code>empinf</code> which calls <code>boot.out\$statistic</code> .                                                                                                                                                                                                                                                                                                                                    |

## Details

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley (1997). Function `boot` must be run prior to running this function to create the object to be passed as `boot.out`.

Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the R values in boot.out a warning is generated and such intervals should not be considered reliable.

## Value

An object of type "bootci" which contains the intervals. It has components

|         |                                                                                                                                                                                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R       | The number of bootstrap replicates on which the intervals were based.                                                                                                                                                                                                                                                              |
| t0      | The observed value of the statistic on the same scale as the intervals.                                                                                                                                                                                                                                                            |
| call    | The call to boot.ci which generated the object.<br>It will also contain one or more of the following components depending on the value of type used in the call to bootci.                                                                                                                                                         |
| normal  | A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.                                                                                                                                         |
| basic   | The intervals calculated using the basic bootstrap method.                                                                                                                                                                                                                                                                         |
| student | The intervals calculated using the studentized bootstrap method.                                                                                                                                                                                                                                                                   |
| percent | The intervals calculated using the bootstrap percentile method.                                                                                                                                                                                                                                                                    |
| bca     | The intervals calculated using the adjusted bootstrap percentile (BCa) method.<br>These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves. |

## Examples

```
confidence intervals for the city data
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
city.boot <- boot(city, ratio, R = 999, stype = "w", sim = "ordinary")
boot.ci(city.boot, conf = c(0.90, 0.95),
 type = c("norm", "basic", "perc", "bca"))

studentized confidence interval for the two sample
difference of means problem using the final two series
of the gravity data.
```

```

diff.means <- function(d, f)
{
 n <- nrow(d)
 gp1 <- 1:table(as.numeric(d$series))[1]
 m1 <- sum(d[gp1,1] * f[gp1])/sum(f[gp1])
 m2 <- sum(d[-gp1,1] * f[-gp1])/sum(f[-gp1])
 ss1 <- sum(d[gp1,1]^2 * f[gp1]) - (m1 * m1 * sum(f[gp1]))
 ss2 <- sum(d[-gp1,1]^2 * f[-gp1]) - (m2 * m2 * sum(f[-gp1]))
 c(m1 - m2, (ss1 + ss2)/(sum(f) - 2))
}

grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
grav1.boot <- boot(grav1, diff.means, R = 999, stype = "f",
 strata = grav1[,2])
boot.ci(grav1.boot, type = c("stud", "norm"))

Nonparametric confidence intervals for mean failure time
of the air-conditioning data as in Example 5.4 of Davison
and Hinkley (1997)
mean.fun <- function(d, i)
{
 m <- mean(d$hours[i])
 n <- length(i)
 v <- (n-1)*var(d$hours[i])/n^2
 c(m, v)
}
air.boot <- boot(aircondit, mean.fun, R = 999)
boot.ci(air.boot, type = c("norm", "basic", "perc", "stud"))

Now using the log transformation
There are two ways of doing this and they both give the
same intervals.

Method 1
boot.ci(air.boot, type = c("norm", "basic", "perc", "stud"),
 h = log, hdot = function(x) 1/x)

Method 2
vt0 <- air.boot$t0[2]/air.boot$t0[1]^2
vt <- air.boot$t[, 2]/air.boot$t[, 1]^2
boot.ci(air.boot, type = c("norm", "basic", "perc", "stud"),
 t0 = log(air.boot$t0[1]), t = log(air.boot$t[,1]),
 var.t0 = vt0, var.t = vt)

```

brambles

*Spatial Location of Bramble Canes***Description**

The brambles data frame has 823 rows and 3 columns.

The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of distance so that the plot can be thought of as a unit square. The bramble canes were also classified by their age.

**Usage**

```
brambles
```

**Format**

This data frame contains the following columns:

- x The x coordinate of the position of the cane in the plot.
- y The y coordinate of the position of the cane in the plot.
- age The age classification of the canes; 0 indicates a newly emerged cane, 1 indicates a one year old cane and 2 indicates a two year old cane.

**Source**

The data were obtained from

---

breslow

*Smoking Deaths Among Doctors*

---

**Description**

The breslow data frame has 10 rows and 5 columns.

In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The breslow data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

**Usage**

breslow

**Format**

This data frame contains the following columns:

- age The mid-point of the 10 year age-group for the doctors.
- smoke An indicator of whether the doctors smoked (1) or not (0).
- n The number of person-years in the category.
- y The number of deaths attributed to coronary artery disease.
- ns The number of smoker years in the category (smoke\*n).

**Source**

The data were obtained from

Breslow, N.E. (1985) Cohort Analysis in Epidemiology. In *A Celebration of Statistics* A.C. Atkinson and S.E. Fienberg (editors), 109–143. Springer-Verlag.

calcium

*Calcium Uptake Data*

---

## Description

The calcium data frame has 27 rows and 2 columns.

Howard Grimes from the Botany Department, North Carolina State University, conducted an experiment for biochemical analysis of intracellular storage and transport of calcium across plasma membrane. Cells were suspended in a solution of radioactive calcium for a certain length of time and then the amount of radioactive calcium that was absorbed by the cells was measured. The experiment was repeated independently with 9 different times of suspension each replicated 3 times.

## Usage

calcium

## Format

This data frame contains the following columns:

time The time (in minutes) that the cells were suspended in the solution.

cal The amount of calcium uptake (nmoles/mg).

## Source

The data were obtained from

Rawlings, J.O. (1988) *Applied Regression Analysis*. Wadsworth and Brooks/Cole Statistics/Probability Series.

---

cane*Sugar-cane Disease Data*

---

**Description**

The cane data frame has 180 rows and 5 columns. The data frame represents a randomized block design with 45 varieties of sugar-cane and 4 blocks.

**Usage**

cane

**Format**

This data frame contains the following columns:

n The total number of shoots in each plot.

r The number of diseased shoots.

x The number of pieces of the stems, out of 50, planted in each plot.

var A factor indicating the variety of sugar-cane in each plot.

block A factor for the blocks.

**Details**

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvao da cana-de-acucar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

**Source**

The data were kindly supplied by Dr. C.G.B. Demetrio of Escola Superior de Agricultura, Universidade de Sao Paolo, Brazil.

| catsM | <i>Weight Data for Domestic Cats</i> |
|-------|--------------------------------------|

---

**Description**

The catsM data frame has 97 rows and 3 columns.

144 adult (over 2kg in weight) cats used for experiments with the drug digitalis had their heart and body weight recorded. 47 of the cats were female and 97 were male. The catsM data frame consists of the data for the male cats. The full data are in dataset [cats](#) in package MASS.

**Usage**

catsM

**Format**

This data frame contains the following columns:

Sex A factor for the sex of the cat (levels are F and M: all cases are M in this subset).

Bwt Body weight in kg.

Hwt Heart weight in g.

**Source**

The data were obtained from

cav

---

*Position of Muscle Caveolae*

---

**Description**

The cav data frame has 138 rows and 2 columns.

The data gives the positions of the individual caveolae in a square region with sides of length 500 units. This grid was originally on a 2.65µm square of muscle fibre. The data are those points falling in the lower left hand quarter of the region used for the dataset caveolae.dat in the **spatial** package by B.D. Ripley (1994).

**Usage**

```
cav
```

**Format**

This data frame contains the following columns:

x The x coordinate of the caveola's position in the region.

y The y coordinate of the caveola's position in the region.

cd4

*CD4 Counts for HIV-Positive Patients***Description**

The cd4 data frame has 20 rows and 2 columns.

CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.

**Usage**

cd4

**Format**

This data frame contains the following columns:

baseline The CD4 counts (in 100's) on admission to the trial.

oneyear The CD4 counts (in 100's) after one year of treatment with the new drug.

**Source**

The data were obtained from

DiCiccio, T.J. and Efron B. (1996) Bootstrap confidence intervals (with Discussion). *Statistical Science*, **11**, 189–228.

censboot

*Bootstrap for Censored Data***Description**

This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

**Usage**

```
censboot(data, statistic, R, F.surv, G.surv, strata = matrix(1,n,2),
 sim = "ordinary", cox = NULL, index = c(1, 2), ...,
 parallel = c("no", "multicore", "snow"),
 ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

- |           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data      | The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for <code>sim = "weird"</code> when it should only have two columns - the times and censoring indicators. The columns of data referenced by the components of <code>index</code> are taken to be the times and censoring indicators.                                                                                                                                                                                                                                                                                                                                                                       |
| statistic | A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the <code>...</code> argument. In the case of <code>sim = "weird"</code> , the data passed to <code>statistic</code> only contains the times and censoring indicator regardless of the actual number of columns in data. In all other cases the data passed to <code>statistic</code> will be of the same form as the original data. When <code>sim = "weird"</code> , the actual number of observations in the resampled data sets may not be the same as the number in data. For this reason, if <code>sim = "weird"</code> and <code>strata</code> is supplied, <code>statistic</code> should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required. |
| R         | The number of bootstrap replicates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| F.surv    | An object returned from a call to <code>survfit</code> giving the survivor function for the data. This is a required argument unless <code>sim = "ordinary"</code> or <code>sim = "model"</code> and <code>cox</code> is missing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| G.surv    | Another object returned from a call to <code>survfit</code> but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to <code>survfit</code> . This is a required argument whenever <code>sim = "cond"</code> or when <code>sim = "model"</code> and <code>cox</code> is supplied.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| strata    | The strata used in the calls to <code>survfit</code> . It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When <code>sim = "weird"</code> only the strata for the survival distribution are used since the                                                                                                                                                                                                                                                                                                                                                                     |

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  | censoring times are considered fixed. When <code>sim = "ordinary"</code> , only one set of strata is used to stratify the observations, this is taken to be the first column of strata when it is a matrix.                                                                                                                                                                                                                                                    |
| <code>sim</code>                 | The simulation type. Possible types are "ordinary" (case resampling), "model" (equivalent to "ordinary" if <code>cox</code> is missing, otherwise it is model-based resampling), "weird" (the weird bootstrap - this cannot be used if <code>cox</code> is supplied), and "cond" (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution).                                                              |
| <code>cox</code>                 | An object returned from <code>coxph</code> . If it is supplied, then <code>F.surv</code> should have been generated by a call of the form <code>survfit(cox)</code> .                                                                                                                                                                                                                                                                                          |
| <code>index</code>               | A vector of length two giving the positions of the columns in data which correspond to the times and censoring indicators respectively.                                                                                                                                                                                                                                                                                                                        |
| <code>...</code>                 | Other named arguments which are passed unchanged to <code>statistic</code> each time it is called. Any such arguments to <code>statistic</code> must follow the arguments which <code>statistic</code> is required to have for the simulation. Beware of partial matching to arguments of <code>censboot</code> listed above, and that arguments named <code>X</code> and <code>FUN</code> cause conflicts in some versions of <b>boot</b> (but not this one). |
| <code>parallel, ncpus, cl</code> | See the help for <b>boot</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Details

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observations.

The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of `Inf` and conversely if it is uncensored it is given a nominal censoring time of `Inf`. This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (`sim = "model"`) or from the conditional censoring distribution as in the previous paragraph (`sim = "cond"`).

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is a least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and `sim` is either "model" or "cond" the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of `Inf`, also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of `Inf` and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.

When `parallel = "snow"` and `cl` is not supplied, `library(survival)` is run in each of the worker processes.

### Value

An object of class "boot" containing the following components:

|                        |                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t0</code>        | The value of statistic when applied to the original data.                                                                                                                                                                                                                                                                               |
| <code>t</code>         | A matrix of bootstrap replicates of the values of statistic.                                                                                                                                                                                                                                                                            |
| <code>R</code>         | The number of bootstrap replicates performed.                                                                                                                                                                                                                                                                                           |
| <code>sim</code>       | The simulation type used. This will usually be the input value of <code>sim</code> unless that was "model" but <code>cox</code> was not supplied, in which case it will be "ordinary".                                                                                                                                                  |
| <code>data</code>      | The data used for the bootstrap. This will generally be the input value of <code>data</code> unless <code>sim = "weird"</code> , in which case it will just be the columns containing the times and the censoring indicators.                                                                                                           |
| <code>seed</code>      | The value of <code>.Random.seed</code> when <code>censboot</code> started work.                                                                                                                                                                                                                                                         |
| <code>statistic</code> | The input value of statistic.                                                                                                                                                                                                                                                                                                           |
| <code>strata</code>    | The strata used in the resampling. When <code>sim = "ordinary"</code> this will be a vector which stratifies the observations, when <code>sim = "weird"</code> it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution. |
| <code>call</code>      | The original call to <code>censboot</code> .                                                                                                                                                                                                                                                                                            |

### Examples

```
library(survival)
Example 3.9 of Davison and Hinkley (1997) does a bootstrap on some
remission times for patients with a type of leukaemia. The patients
were divided into those who received maintenance chemotherapy and
those who did not. Here we are interested in the median remission
```

```

time for the two groups.
data(aml, package = "boot") # not the version in survival.
aml.fun <- function(data) {
 surv <- survfit(Surv(time, cens) ~ group, data = data)
 out <- NULL
 st <- 1
 for (s in 1:length(surv$strata)) {
 inds <- st:(st + surv$strata[s]-1)
 md <- min(surv$time[inds[1-surv$surv[inds] >= 0.5]])
 st <- st + surv$strata[s]
 out <- c(out, md)
 }
 out
}
aml.case <- censboot(aml, aml.fun, R = 499, strata = aml$group)

Now we will look at the same statistic using the conditional
bootstrap and the weird bootstrap. For the conditional bootstrap
the survival distribution is stratified but the censoring
distribution is not.

aml.s1 <- survfit(Surv(time, cens) ~ group, data = aml)
aml.s2 <- survfit(Surv(time-0.001*cens, 1-cens) ~ 1, data = aml)
aml.cond <- censboot(aml, aml.fun, R = 499, strata = aml$group,
 F.surv = aml.s1, G.surv = aml.s2, sim = "cond")

For the weird bootstrap we must redefine our function slightly since
the data will not contain the group number.
aml.fun1 <- function(data, str) {
 surv <- survfit(Surv(data[, 1], data[, 2]) ~ str)
 out <- NULL
 st <- 1
 for (s in 1:length(surv$strata)) {
 inds <- st:(st + surv$strata[s] - 1)
 md <- min(surv$time[inds[1-surv$surv[inds] >= 0.5]])
 st <- st + surv$strata[s]
 out <- c(out, md)
 }
 out
}
aml.wei <- censboot(cbind(aml$time, aml$cens), aml.fun1, R = 499,
 strata = aml$group, F.surv = aml.s1, sim = "weird")

Now for an example where a cox regression model has been fitted
the data we will look at the melanoma data of Example 7.6 from
Davison and Hinkley (1997). The fitted model assumes that there
is a different survival distribution for the ulcerated and
non-ulcerated groups but that the thickness of the tumour has a
common effect. We will also assume that the censoring distribution
is different in different age groups. The statistic of interest
is the linear predictor. This is returned as the values at a
number of equally spaced points in the range of interest.
data(melanoma, package = "boot")
library(splines)# for ns
mel.cox <- coxph(Surv(time, status == 1) ~ ns(thickness, df=4) + strata(ulcer),
 data = melanoma)

```

```

mel.surv <- survfit(mel.cox)
agec <- cut(melanoma$age, c(0, 39, 49, 59, 69, 100))
mel.cens <- survfit(Surv(time - 0.001*(status == 1), status != 1) ~
 strata(agec), data = melanoma)
mel.fun <- function(d) {
 t1 <- ns(d$thickness, df=4)
 cox <- coxph(Surv(d$time, d$status == 1) ~ t1+strata(d$ulcer))
 ind <- !duplicated(d$thickness)
 u <- d$thickness[!ind]
 eta <- cox$linear.predictors[!ind]
 sp <- smooth.spline(u, eta, df=20)
 th <- seq(from = 0.25, to = 10, by = 0.25)
 predict(sp, th)$y
}
mel.str <- cbind(melanoma$ulcer, agec)

this is slow!
mel.mod <- censboot(melanoma, mel.fun, R = 499, F.surv = mel.surv,
 G.surv = mel.cens, cox = mel.cox, strata = mel.str, sim = "model")
To plot the original predictor and a 95% pointwise envelope for it
mel.env <- envelope(mel.mod)$point
th <- seq(0.25, 10, by = 0.25)
plot(th, mel.env[1,], ylim = c(-2, 2),
 xlab = "thickness (mm)", ylab = "linear predictor", type = "n")
lines(th, mel.mod$t0, lty = 1)
matlines(th, t(mel.env), lty = 2)

```

channing

Channing House Data

---

## Description

The channing data frame has 462 rows and 5 columns.

Channing House is a retirement centre in Palo Alto, California. These data were collected between the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed through the centre. For each of these, their age on entry and also on leaving or death was recorded. A large number of the observations were censored mainly due to the resident being alive on July 1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at Channing House. Differences between the survival of the sexes, taking age into account, was one of the primary concerns of this study.

## Usage

```
channing
```

## Format

This data frame contains the following columns:

**sex** A factor for the sex of each resident ("Male" or "Female").

**entry** The residents age (in months) on entry to the centre

**exit** The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever event occurred first.

time The length of time (in months) that the resident spent at Channing House.  
(time=exit-entry)

cens The indicator of right censoring. 1 indicates that the resident died at Channing House, 0 indicates that they left the house prior to July 1, 1975 or that they were still alive and living in the centre at that date.

claridge

*Genetic Links to Left-handedness*

---

### Description

The claridge data frame has 37 rows and 2 columns.

The data are from an experiment which was designed to look for a relationship between a certain genetic characteristic and handedness. The 37 subjects were women who had a son with mental retardation due to inheriting a defective X-chromosome. For each such mother a genetic measurement of their DNA was made. Larger values of this measurement are known to be linked to the defective gene and it was hypothesized that larger values might also be linked to a progressive shift away from right-handedness. Each woman also filled in a questionnaire regarding which hand they used for various tasks. From these questionnaires a measure of hand preference was found for each mother. The scale of this measure goes from 1, indicating someone who always favours their right hand, to 8, indicating someone who always favours their left hand. Between these two extremes are people who favour one hand for some tasks and the other for other tasks.

### Usage

claridge

### Format

This data frame contains the following columns:

dnan The genetic measurement on each woman's DNA.

hand The measure of left-handedness on an integer scale from 1 to 8.

### Source

The data were kindly made available by Dr. Gordon S. Claridge from the Department of Experimental Psychology, University of Oxford.

---

coal

*Dates of Coal Mining Disasters*

---

**Description**

The coal data frame has 191 rows and 1 columns.

This data frame gives the dates of 191 explosions in coal mines which resulted in 10 or more fatalities. The time span of the data is from March 15, 1851 until March 22 1962.

**Usage**

coal

**Format**

This data frame contains the following column:

date The date of the disaster. The integer part of date gives the year. The day is represented as the fraction of the year that had elapsed on that day.

**Source**

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) *A Handbook of Small Data Sets*, Chapman and Hall.

control

*Control Variate Calculations***Description**

This function will find control variate estimates from a bootstrap output object. It can either find the adjusted bias estimate using post-simulation balancing or it can estimate the bias, variance, third cumulant and quantiles, using the linear approximation as a control variate.

**Usage**

```
control(boot.out, L = NULL, distn = NULL, index = 1, t0 = NULL,
 t = NULL, bias.adj = FALSE, alpha = NULL, ...)
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| boot.out | A bootstrap output object returned from boot. The bootstrap replicates must have been generated using the usual nonparametric bootstrap.                                                                                                                                                                                                |
| L        | The empirical influence values for the statistic of interest. If L is not supplied then empinf is called to calculate them from boot.out.                                                                                                                                                                                               |
| distn    | If present this must be the output from smooth.spline giving the distribution function of the linear approximation. This is used only if bias.adj is FALSE. Normally this would be found using a saddlepoint approximation. If it is not supplied in that case then it is calculated by saddle.distn.                                   |
| index    | The index of the variable of interest in the output of boot.out\$statistic.                                                                                                                                                                                                                                                             |
| t0       | The observed value of the statistic of interest on the original data set boot.out\$data. This argument is used only if bias.adj is FALSE. The input value is ignored if t is not also supplied. The default value is boot.out\$t0[index].                                                                                               |
| t        | The bootstrap replicate values of the statistic of interest. This argument is used only if bias.adj is FALSE. The input is ignored if t0 is not supplied also. The default value is boot.out\$t[,index].                                                                                                                                |
| bias.adj | A logical variable which if TRUE specifies that the adjusted bias estimate using post-simulation balance is all that is required. If bias.adj is FALSE (default) then the linear approximation to the statistic is calculated and used as a control variate in estimates of the bias, variance and third cumulant as well as quantiles. |
| alpha    | The alpha levels for the required quantiles if bias.adj is FALSE.                                                                                                                                                                                                                                                                       |
| ...      | Any additional arguments that boot.out\$statistic requires. These are passed unchanged every time boot.out\$statistic is called. boot.out\$statistic is called once if bias.adj is TRUE, otherwise it may be called by empinf for empirical influence calculations if L is not supplied.                                                |

**Details**

If bias.adj is FALSE then the linear approximation to the statistic is found and evaluated at each bootstrap replicate. Then using the equation  $T^* = Tl^* + (T^* - Tl^*)$ , moment estimates can be found. For quantile estimation the distribution of the linear approximation to t is approximated very accurately by saddlepoint methods, this is then combined with the bootstrap replicates to approximate the bootstrap distribution of t and hence to estimate the bootstrap quantiles of t.

**Value**

If `bias.adj` is `TRUE` then the returned value is the adjusted bias estimate.

If `bias.adj` is `FALSE` then the returned value is a list with the following components

|                        |                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>L</code>         | The empirical influence values used. These are the input values if supplied, and otherwise they are the values calculated by <code>empinf</code> .                                                                                                                                                                         |
| <code>tL</code>        | The linear approximations to the bootstrap replicates <code>t</code> of the statistic of interest.                                                                                                                                                                                                                         |
| <code>bias</code>      | The control estimate of bias using the linear approximation to <code>t</code> as a control variate.                                                                                                                                                                                                                        |
| <code>var</code>       | The control estimate of variance using the linear approximation to <code>t</code> as a control variate.                                                                                                                                                                                                                    |
| <code>k3</code>        | The control estimate of the third cumulant using the linear approximation to <code>t</code> as a control variate.                                                                                                                                                                                                          |
| <code>quantiles</code> | A matrix with two columns; the first column are the alpha levels used for the quantiles and the second column gives the corresponding control estimates of the quantiles using the linear approximation to <code>t</code> as a control variate.                                                                            |
| <code>distn</code>     | An output object from <code>smooth.spline</code> describing the saddlepoint approximation to the bootstrap distribution of the linear approximation to <code>t</code> . If <code>distn</code> was supplied on input then this is the same as the input otherwise it is calculated by a call to <code>saddle.distn</code> . |

**Examples**

```
Use of control variates for the variance of the air-conditioning data
mean.fun <- function(d, i)
{
 m <- mean(d$hours[i])
 n <- nrow(d)
 v <- (n-1)*var(d$hours[i])/n^2
 c(m, v)
}
air.boot <- boot(aircondit, mean.fun, R = 999)
control(air.boot, index = 2, bias.adj = TRUE)
air.cont <- control(air.boot, index = 2)
Now let us try the variance on the log scale.
air.cont1 <- control(air.boot, t0 = log(air.boot$t0[2]),
 t = log(air.boot$t[, 2]))
```

|------|--------------------------------|
| corr | <i>Correlation Coefficient</i> |
|------|--------------------------------|

---

### Description

Calculates the weighted correlation given a data set and a set of weights.

### Usage

```
corr(d, w = rep(1, nrow(d))/nrow(d))
```

### Arguments

|   |                                                                                                                                                                                                    |
|---|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d | A matrix with two columns corresponding to the two variables whose correlation we wish to calculate.                                                                                               |
| w | A vector of weights to be applied to each pair of observations. The default is equal weights for each pair. Normalization takes place within the function so <code>sum(w)</code> need not equal 1. |

### Details

This function finds the correlation coefficient in weighted form. This is often useful in bootstrap methods since it allows for numerical differentiation to get the empirical influence values. It is also necessary to have the statistic in this form to find ABC intervals.

### Value

The correlation coefficient between `d[, 1]` and `d[, 2]`.

|      |                                        |
|------|----------------------------------------|
| cum3 | <i>Calculate Third Order Cumulants</i> |
|------|----------------------------------------|

---

### Description

Calculates an estimate of the third cumulant, or skewness, of a vector. Also, if more than one vector is specified, a product-moment of order 3 is estimated.

### Usage

```
cum3(a, b = a, c = a, unbiased = TRUE)
```

**Arguments**

|          |                                                                                                                                |
|----------|--------------------------------------------------------------------------------------------------------------------------------|
| a        | A vector of observations.                                                                                                      |
| b        | Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a. |
| c        | Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a. |
| unbiased | A logical value indicating whether the unbiased estimator should be used.                                                      |

**Details**

The unbiased estimator uses a multiplier of  $n/((n-1)*(n-2))$  where  $n$  is the sample size, if unbiased is FALSE then a multiplier of  $1/n$  is used. This is multiplied by  $\text{sum}((a-\text{mean}(a))*(b-\text{mean}(b))*(c-\text{mean}(c)))$  to give the required estimate.

**Value**

The required estimate.

---

cv.glm

---

*Cross-validation for Generalized Linear Models*

---

**Description**

This function calculates the estimated K-fold cross-validation prediction error for generalized linear models.

**Usage**

```
cv.glm(data, glmfit, cost, K)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data   | A matrix or data frame containing the data. The rows should be cases and the columns correspond to variables, one of which is the response.                                                                                                                                                                                                                                                                                                                                                    |
| glmfit | An object of class "glm" containing the results of a generalized linear model fitted to data.                                                                                                                                                                                                                                                                                                                                                                                                  |
| cost   | A function of two vector arguments specifying the cost function for the cross-validation. The first argument to cost should correspond to the observed responses and the second argument should correspond to the predicted or fitted responses from the generalized linear model. cost must return a non-negative scalar value. The default is the average squared error function.                                                                                                            |
| K      | The number of groups into which the data should be split to estimate the cross-validation prediction error. The value of K must be such that all groups are of approximately equal size. If the supplied value of K does not satisfy this criterion then it will be set to the closest integer which does and a warning is generated specifying the value of K used. The default is to set K equal to the number of observations in data which gives the usual leave-one-out cross-validation. |

## Details

The data is divided randomly into K groups. For each group the generalized linear model is fit to data omitting that group, then the function cost is applied to the observed responses in the group that was omitted from the fit and the prediction made by the fitted models for those observations.

When K is the number of observations leave-one-out cross-validation is used and all the possible splits of the data are used. When K is less than the number of observations the K splits to be used are found by randomly partitioning the data into K groups of approximately equal size. In this latter case a certain amount of bias is introduced. This can be reduced by using a simple adjustment (see equation 6.48 in Davison and Hinkley, 1997). The second value returned in `delta` is the estimate adjusted by this method.

## Value

The returned value is a list with the following components.

|                    |                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>call</code>  | The original call to <code>cv.glm</code> .                                                                                                                                                                                                                                          |
| <code>K</code>     | The value of K used for the K-fold cross validation.                                                                                                                                                                                                                                |
| <code>delta</code> | A vector of length two. The first component is the raw cross-validation estimate of prediction error. The second component is the adjusted cross-validation estimate. The adjustment is designed to compensate for the bias introduced by not using leave-one-out cross-validation. |
| <code>seed</code>  | The value of <code>.Random.seed</code> when <code>cv.glm</code> was called.                                                                                                                                                                                                         |

## Side Effects

The value of `.Random.seed` is updated.

```

darwin

*Darwin's Plant Height Differences***Description**

The darwin data frame has 15 rows and 1 columns.

Charles Darwin conducted an experiment to examine the superiority of cross-fertilized plants over self-fertilized plants. 15 pairs of plants were used. Each pair consisted of one cross-fertilized plant and one self-fertilized plant which germinated at the same time and grew in the same pot. The plants were measured at a fixed time after planting and the difference in heights between the cross- and self-fertilized plants are recorded in eighths of an inch.

**Usage**

```
darwin
```

**Format**

This data frame contains the following column:

y The difference in heights for the pairs of plants (in units of 0.125 inches).

**Source**

The data were obtained from

Fisher, R.A. (1935) *Design of Experiments*. Oliver and Boyd.

downs.bc*Incidence of Down's Syndrome in British Columbia*

---

**Description**

The downs.bc data frame has 30 rows and 3 columns.

Down's syndrome is a genetic disorder caused by an extra chromosome 21 or a part of chromosome 21 being translocated to another chromosome. The incidence of Down's syndrome is highly dependent on the mother's age and rises sharply after age 30. In the 1960's a large scale study of the effect of maternal age on the incidence of Down's syndrome was conducted at the British Columbia Health Surveillance Registry. These are the data which was collected in that study.

Mothers were classified by age. Most groups correspond to the age in years but the first group comprises all mothers with ages in the range 15-17 and the last is those with ages 46-49. No data for mothers over 50 or below 15 were collected.

**Usage**

downs.bc

**Format**

This data frame contains the following columns:

**age** The average age of all mothers in the age category.

**m** The total number of live births to mothers in the age category.

**r** The number of cases of Down's syndrome.

ducks

*Behavioral and Plumage Characteristics of Hybrid Ducks*

---

### Description

The ducks data frame has 11 rows and 2 columns.

Each row of the data frame represents a male duck who is a second generation cross of mallard and pintail ducks. For 11 such ducks a behavioural and plumage index were calculated. These were measured on scales devised for this experiment which was to examine whether there was any link between which species the ducks resembled physically and which they resembled in behaviour. The scale for the physical appearance ranged from 0 (identical in appearance to a mallard) to 20 (identical to a pintail). The behavioural traits of the ducks were on a scale from 0 to 15 with lower numbers indicating closer to mallard-like in behaviour.

### Usage

ducks

### Format

This data frame contains the following columns:

plumage The index of physical appearance based on the plumage of individual ducks.

behaviour The index of behavioural characteristics of the ducks.

### Source

The data were obtained from

Larsen, R.J. and Marx, M.L. (1986) *An Introduction to Mathematical Statistics and its Applications* (Second Edition). Prentice-Hall.

EEF.profile

*Empirical Likelihoods***Description**

Construct the empirical log likelihood or empirical exponential family log likelihood for a mean.

**Usage**

```
EEF.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
 u = function(y, t) y - t)
EL.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
 u = function(y, t) y - t)
```

**Arguments**

|      |                                                                                                                |
|------|----------------------------------------------------------------------------------------------------------------|
| y    | A vector or matrix of data                                                                                     |
| tmin | The minimum value of the range over which the likelihood should be computed. This must be larger than min(y).  |
| tmax | The maximum value of the range over which the likelihood should be computed. This must be smaller than max(y). |
| n.t  | The number of points between tmin and tmax at which the value of the log-likelihood should be computed.        |
| u    | A function of the data and the parameter.                                                                      |

**Details**

These functions calculate the log likelihood for a mean using either an empirical likelihood or an empirical exponential family likelihood. They are supplied as part of the package boot for demonstration purposes with the practicals in chapter 10 of Davison and Hinkley (1997). The functions are not intended for general use and are not supported as part of the bootpackage. For more general and more robust code to calculate empirical likelihoods see Professor A. B. Owen's empirical likelihood home page at the URL <https://artowen.su.domains/empirical/>

**Value**

A matrix with n.t rows. The first column contains the values of the parameter used. The second column of the output of EL.profile contains the values of the empirical log likelihood. The second and third columns of the output of EEF.profile contain two versions of the empirical exponential family log-likelihood. The final column of the output matrix contains the values of the Lagrange multiplier used in the optimization procedure.

*Empirical Influence Values***Description**

This function calculates the empirical influence values for a statistic applied to a data set. It allows four types of calculation, namely the infinitesimal jackknife (using numerical differentiation), the usual jackknife estimates, the ‘positive’ jackknife estimates and a method which estimates the empirical influence values using regression of bootstrap replicates of the statistic. All methods can be used with one or more samples.

**Usage**

```
empinf(boot.out = NULL, data = NULL, statistic = NULL,
 type = NULL, stype = NULL, index = 1, t = NULL,
 strata = rep(1, n), eps = 0.001, ...)
```

**Arguments**

- |           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| boot.out  | A bootstrap object created by the function boot. If type is "reg" then this argument is required. For any of the other types it is an optional argument. If it is included when optional then the values of data, statistic, stype, and strata are taken from the components of boot.out and any values passed to empinf directly are ignored.                                                                                                                                                                                                                                                                                                                                                                              |
| data      | A vector, matrix or data frame containing the data for which empirical influence values are required. It is a required argument if boot.out is not supplied. If boot.out is supplied then data is set to boot.out\$data and any value supplied is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| statistic | The statistic for which empirical influence values are required. It must be a function of at least two arguments, the data set and a vector of weights, frequencies or indices. The nature of the second argument is given by the value of stype. Any other arguments that it takes must be supplied to empinf and will be passed to statistic unchanged. This is a required argument if boot.out is not supplied, otherwise its value is taken from boot.out and any value supplied here will be ignored.                                                                                                                                                                                                                  |
| type      | The calculation type to be used for the empirical influence values. Possible values of type are "inf" (infinitesimal jackknife), "jack" (usual jackknife), "pos" (positive jackknife), and "reg" (regression estimation). The default value depends on the other arguments. If t is supplied then the default value of type is "reg" and boot.out should be present so that its frequency array can be found. If t is not supplied then if stype is "w", the default value of type is "inf"; otherwise, if boot.out is present the default is "reg". If none of these conditions apply then the default is "jack". Note that it is an error for type to be "reg" if boot.out is missing or to be "inf" if stype is not "w". |
| stype     | A character variable giving the nature of the second argument to statistic. It can take on three values: "w" (weights), "f" (frequencies), or "i" (indices). If boot.out is supplied the value of stype is set to boot.out\$stype and any value supplied here is ignored. Otherwise it is an optional argument which defaults to "w". If type is "inf" then stype MUST be "w".                                                                                                                                                                                                                                                                                                                                              |

|        |                                                                                                                                                                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| index  | An integer giving the position of the variable of interest in the output of statistic.                                                                                                                                                                                                              |
| t      | A vector of length <code>boot.out\$R</code> which gives the bootstrap replicates of the statistic of interest. <code>t</code> is used only when <code>type</code> is <code>reg</code> and it defaults to <code>boot.out\$t[,index]</code> .                                                         |
| strata | An integer vector or a factor specifying the strata for multi-sample problems. If <code>boot.out</code> is supplied the value of <code>strata</code> is set to <code>boot.out\$strata</code> . Otherwise it is an optional argument which has default corresponding to the single sample situation. |
| eps    | This argument is used only if <code>type</code> is <code>"inf"</code> . In that case the value of epsilon to be used for numerical differentiation will be <code>eps</code> divided by the number of observations in data.                                                                          |
| ...    | Any other arguments that <code>statistic</code> takes. They will be passed unchanged to <code>statistic</code> every time that it is called.                                                                                                                                                        |

### Details

If `type` is `"inf"` then numerical differentiation is used to approximate the empirical influence values. This makes sense only for statistics which are written in weighted form (i.e. `stype` is `"w"`). If `type` is `"jack"` then the usual leave-one-out jackknife estimates of the empirical influence are returned. If `type` is `"pos"` then the positive (include-one-twice) jackknife values are used. If `type` is `"reg"` then a bootstrap object must be supplied. The regression method then works by regressing the bootstrap replicates of `statistic` on the frequency array from which they were derived. The bootstrap frequency array is obtained through a call to `boot.array`. Further details of the methods are given in Section 2.7 of Davison and Hinkley (1997).

Empirical influence values are often used frequently in nonparametric bootstrap applications. For this reason many other functions call `empinf` when they are required. Some examples of their use are for nonparametric delta estimates of variance, BCa intervals and finding linear approximations to statistics for use as control variates. They are also used for antithetic bootstrap resampling.

### Value

A vector of the empirical influence values of `statistic` applied to data. The values will be in the same order as the observations in data.

### Warning

All arguments to `empinf` must be passed using the `name = value` convention. If this is not followed then unpredictable errors can occur.

## Examples

```
The empirical influence values for the ratio of means in
the city data.
ratio <- function(d, w) sum(d$x * w) / sum(d$u * w)
empinf(data = city, statistic = ratio)
city.boot <- boot(city, ratio, 499, stype = "w")
empinf(boot.out = city.boot, type = "reg")

A statistic that may be of interest in the difference of means
problem is the t-statistic for testing equality of means. In
the bootstrap we get replicates of the difference of means and
the variance of that statistic and then want to use this output
to get the empirical influence values of the t-statistic.
grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
grav.fun <- function(dat, w) {
 strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
 d <- dat[, 1]
 ns <- tabulate(strata)
 w <- w / tapply(w, strata, sum)[strata]
 mns <- as.vector(tapply(d * w, strata, sum)) # drop names
 mn2 <- tapply(d * d * w, strata, sum)
 s2hat <- sum((mn2 - mns^2) / ns)
 c(mns[2] - mns[1], s2hat)
}

grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
 strata = grav1[, 2])

Since the statistic of interest is a function of the bootstrap
statistics, we must calculate the bootstrap replicates and pass
them to empinf using the t argument.
grav.z <- (grav.boot$t[,1] - grav.boot$t[0,1]) / sqrt(grav.boot$t[,2])
empinf(boot.out = grav.boot, t = grav.z)
```

---

envelope

---

*Confidence Envelopes for Curves*

---

## Description

This function calculates overall and pointwise confidence envelopes for a curve based on bootstrap replicates of the curve evaluated at a number of fixed points.

## Usage

```
envelope(boot.out = NULL, mat = NULL, level = 0.95, index = 1:ncol(mat))
```

## Arguments

|          |                                                                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| boot.out | An object of class "boot" for which boot.out\$t contains the replicates of the curve at a number of fixed points.                                                                     |
| mat      | A matrix of bootstrap replicates of the values of the curve at a number of fixed points. This is a required argument if boot.out is not supplied and is set to boot.out\$t otherwise. |

|       |                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| level | The confidence level of the envelopes required. The default is to find 95% confidence envelopes. It can be a scalar or a vector of length 2. If it is scalar then both the pointwise and the overall envelopes are found at that level. If is a vector then the first element gives the level for the pointwise envelope and the second gives the level for the overall envelope. |
| index | The numbers of the columns of <code>mat</code> which contain the bootstrap replicates. This can be used to ensure that other statistics which may have been calculated in the bootstrap are not considered as values of the function.                                                                                                                                             |

### Details

The pointwise envelope is found by simply looking at the quantiles of the replicates at each point. The overall error for that envelope is then calculated using equation (4.17) of Davison and Hinkley (1997). A sequence of pointwise envelopes is then found until one of them has overall error approximately equal to the level required. If no such envelope can be found then the envelope returned will just contain the extreme values of each column of `mat`.

### Value

A list with the following components :

|         |                                                                                                                                                                         |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| point   | A matrix with two rows corresponding to the values of the upper and lower pointwise confidence envelope at the same points as the bootstrap replicates were calculated. |
| overall | A matrix similar to <code>point</code> but containing the envelope which controls the overall error.                                                                    |
| k.pt    | The quantiles used for the pointwise envelope.                                                                                                                          |
| err.pt  | A vector with two components, the first gives the pointwise error rate for the pointwise envelope, and the second the overall error rate for that envelope.             |
| k.ov    | The quantiles used for the overall envelope.                                                                                                                            |
| err.ov  | A vector with two components, the first gives the pointwise error rate for the overall envelope, and the second the overall error rate for that envelope.               |
| err.nom | A vector of length 2 giving the nominal error rates for the pointwise and the overall envelopes.                                                                        |

|----------|----------------------------|
| exp.tilt | <i>Exponential Tilting</i> |
|----------|----------------------------|

---

**Description**

This function calculates exponentially tilted multinomial distributions such that the resampling distributions of the linear approximation to a statistic have the required means.

**Usage**

```
exp.tilt(L, theta = NULL, t0 = 0, lambda = NULL,
 strata = rep(1, length(L)))
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| L      | The empirical influence values for the statistic of interest based on the observed data. The length of L should be the same as the size of the original data set. Typically L will be calculated by a call to empinf.                                                                                                                                                                |
| theta  | The value at which the tilted distribution is to be centred. This is not required if lambda is supplied but is needed otherwise.                                                                                                                                                                                                                                                     |
| t0     | The current value of the statistic. The default is that the statistic equals 0.                                                                                                                                                                                                                                                                                                      |
| lambda | The Lagrange multiplier(s). For each value of lambda a multinomial distribution is found with probabilities proportional to $\exp(\text{lambda} * L)$ . In general lambda is not known and so theta would be supplied, and the corresponding value of lambda found. If both lambda and theta are supplied then lambda is ignored and the multipliers for tilting to theta are found. |
| strata | A vector or factor of the same length as L giving the strata for the observed data and the empirical influence values L.                                                                                                                                                                                                                                                             |

**Details**

Exponential tilting involves finding a set of weights for a data set to ensure that the bootstrap distribution of the linear approximation to a statistic of interest has mean theta. The weights chosen to achieve this are given by  $p[j]$  proportional to  $\exp(\text{lambda} * L[j] / n)$ , where n is the number of data points. lambda is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value theta. Thus lambda is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function nlmin. If this minimum is not equal to zero then the method fails.

Typically exponential tilting is used to find suitable weights for importance resampling. If a small tail probability or quantile of the distribution of the statistic of interest is required then a more efficient simulation is to centre the resampling distribution close to the point of interest and then use the functions `imp.prob` or `imp.quantile` to estimate the required quantity.

Another method of achieving a similar shifting of the distribution is through the use of `smooth.f`. The function `tilt.boot` uses `exp.tilt` or `smooth.f` to find the weights for a tilted bootstrap.

## Value

A list with the following components :

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>p</code>      | The tilted probabilities. There will be <code>m</code> distributions where <code>m</code> is the length of <code>theta</code> (or <code>lambda</code> if supplied). If <code>m</code> is 1 then <code>p</code> is a vector of <code>length(L)</code> probabilities. If <code>m</code> is greater than 1 then <code>p</code> is a matrix with <code>m</code> rows, each of which contain <code>length(L)</code> probabilities. In this case the vector <code>p[i,]</code> is the distribution tilted to <code>theta[i]</code> . <code>p</code> is in the form required by the argument <code>weights</code> of the function <code>boot</code> for importance resampling. |
| <code>lambda</code> | The Lagrange multiplier used in the equation to determine the tilted probabilities. <code>lambda</code> is a vector of the same length as <code>theta</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>theta</code>  | The values of <code>theta</code> to which the distributions have been tilted. In general this will be the input value of <code>theta</code> but if <code>lambda</code> was supplied then this is the vector of the corresponding <code>theta</code> values.                                                                                                                                                                                                                                                                                                                                                                                                             |

## Examples

```
Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
distribution of the studentized statistic to be centred at the observed
value of the test statistic 1.84. This can be achieved as follows.
grav1 <- gravity[as.numeric(gravity[,2]) >= 7 ,]
grav.fun <- function(dat, w, orig) {
 strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
 d <- dat[, 1]
 ns <- tabulate(strata)
 w <- w/tapply(w, strata, sum)[strata]
 mns <- as.vector(tapply(d * w, strata, sum)) # drop names
 mn2 <- tapply(d * d * w, strata, sum)
 s2hat <- sum((mn2 - mns^2)/ns)
 c(mns[2]-mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.L <- empinf(data = grav1, statistic = grav.fun, stype = "w",
 strata = grav1[,2], index = 3, orig = grav.z0[1])
grav.tilt <- exp.tilt(grav.L, grav.z0[3], strata = grav1[,2])
```

```
boot(grav1, grav.fun, R = 499, stype = "w", weights = grav.tilt$p,
 strata = grav1[,2], orig = grav.z0[1])
```

fir

*Counts of Balsam-fir Seedlings*

### Description

The fir data frame has 50 rows and 3 columns.

The number of balsam-fir seedlings in each quadrant of a grid of 50 five foot square quadrants were counted. The grid consisted of 5 rows of 10 quadrants in each row.

### Usage

```
fir
```

### Format

This data frame contains the following columns:

count The number of seedlings in the quadrant.

row The row number of the quadrant.

col The quadrant number within the row.

### Source

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

freq.array

*Bootstrap Frequency Arrays*

### Description

Take a matrix of indices for nonparametric bootstrap resamples and return the frequencies of the original observations in each resample.

### Usage

```
freq.array(i.array)
```

### Arguments

i.array This will be an matrix of integers between 1 and n, where n is the number of observations in a data set. The matrix will have n columns and R rows where R is the number of bootstrap resamples. Such matrices are found by boot when doing nonparametric bootstraps. They can also be found after a bootstrap has been run through the function boot.array.

**Value**

A matrix of the same dimensions as the input matrix. Each row of the matrix corresponds to a single bootstrap resample. Each column of the matrix corresponds to one of the original observations and specifies its frequency in each bootstrap resample. Thus the first column tells us how often the first observation appeared in each bootstrap resample. Such frequency arrays are often useful for diagnostic purposes such as the jackknife-after-bootstrap plot. They are also necessary for the regression estimates of empirical influence values and for finding importance sampling weights.

|-------|------------------------------------|
| frets | <i>Head Dimensions in Brothers</i> |
|-------|------------------------------------|

---

**Description**

The frets data frame has 25 rows and 4 columns.

The data consist of measurements of the length and breadth of the heads of pairs of adult brothers in 25 randomly sampled families. All measurements are expressed in millimetres.

**Usage**

```
frets
```

**Format**

This data frame contains the following columns:

- l1 The head length of the eldest son.
- b1 The head breadth of the eldest son.
- l2 The head length of the second son.
- b2 The head breadth of the second son.

**Source**

The data were obtained from

Frets, G.P. (1921) Heredity of head form in man. *Genetica*, **3**, 193.

glm.diag*Generalized Linear Model Diagnostics*

---

**Description**

Calculates jackknife deviance residuals, standardized deviance residuals, standardized Pearson residuals, approximate Cook statistic, leverage and estimated dispersion.

**Usage**

```
glm.diag(glmfit)
```

**Arguments**

glmfit                  glmfit is a glm.object - the result of a call to glm()

**Value**

Returns a list with the following components

|      |                                                                                                                                                                                                                                  |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| res  | The vector of jackknife deviance residuals.                                                                                                                                                                                      |
| rd   | The vector of standardized deviance residuals.                                                                                                                                                                                   |
| rp   | The vector of standardized Pearson residuals.                                                                                                                                                                                    |
| cook | The vector of approximate Cook statistics.                                                                                                                                                                                       |
| h    | The vector of leverages of the observations.                                                                                                                                                                                     |
| sd   | The value used to standardize the residuals. This is the estimate of residual standard deviation in the Gaussian family and is the square root of the estimated shape parameter in the Gamma family. In all other cases it is 1. |

**Note**

See the help for [glm.diag.plots](#) for an example of the use of glm.diag.

glm.diag.plots

*Diagnostics plots for generalized linear models***Description**

Makes plot of jackknife deviance residuals against linear predictor, normal scores plots of standardized deviance residuals, plot of approximate Cook statistics against leverage/(1-leverage), and case plot of Cook statistic.

**Usage**

```
glm.diag.plots(glmfit, glmdiag = glm.diag(glmfit), subset = NULL,
 iden = FALSE, labels = NULL, ret = FALSE)
```

**Arguments**

|         |                                                                                                                                                                                                                                                                                                                                                                                               |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| glmfit  | glm.object : the result of a call to glm()                                                                                                                                                                                                                                                                                                                                                    |
| glmdiag | Diagnostics of glmfit obtained from a call to glm.diag. If it is not supplied then it is calculated.                                                                                                                                                                                                                                                                                          |
| subset  | Subset of data for which glm fitting performed: should be the same as the subset option used in the call to glm() which generated glmfit. Needed only if the subset= option was used in the call to glm.                                                                                                                                                                                      |
| iden    | A logical argument. If TRUE then, after the plots are drawn, the user will be prompted for an integer between 0 and 4. A positive integer will select a plot and invoke identify() on that plot. After exiting identify(), the user is again prompted, this loop continuing until the user responds to the prompt with 0. If iden is FALSE (default) the user cannot interact with the plots. |
| labels  | A vector of labels for use with identify() if iden is TRUE. If it is not supplied then the labels are derived from glmfit.                                                                                                                                                                                                                                                                    |
| ret     | A logical argument indicating if glmdiag should be returned. The default is FALSE.                                                                                                                                                                                                                                                                                                            |

**Details**

The diagnostics required for the plots are calculated by glm.diag. These are then used to produce the four plots on the current graphics device.

The plot on the top left is a plot of the jackknife deviance residuals against the fitted values.

The plot on the top right is a normal QQ plot of the standardized deviance residuals. The dotted line is the expected line if the standardized residuals are normally distributed, i.e. it is the line with intercept 0 and slope 1.

The bottom two panels are plots of the Cook statistics. On the left is a plot of the Cook statistics against the standardized leverages. In general there will be two dotted lines on this plot. The horizontal line is at  $8/(n-2p)$  where  $n$  is the number of observations and  $p$  is the number of parameters estimated. Points above this line may be points with high influence on the model. The vertical line is at  $2p/(n-2p)$  and points to the right of this line have high leverage compared to the variance of the raw residual at that point. If all points are below the horizontal line or to the left of the vertical line then the line is not shown.

The final plot again shows the Cook statistic this time plotted against case number enabling us to find which observations are influential.

Use of `iden=T` is encouraged for proper exploration of these four plots as a guide to how well the model fits the data and whether certain observations have an unduly large effect on parameter estimates.

### Value

If `ret` is TRUE then the value of `glm.diag` is returned otherwise there is no returned value.

### Side Effects

The current device is cleared and four plots are plotted by use of `split.screen(c(2,2))`. If `iden` is TRUE, interactive identification of points is enabled. All screens are closed, but not cleared, on termination of the function.

---

gravity

*Acceleration Due to Gravity*

---

### Description

The gravity data frame has 81 rows and 2 columns.

The grav data set has 26 rows and 2 columns.

Between May 1934 and July 1935, the National Bureau of Standards in Washington D.C. conducted a series of experiments to estimate the acceleration due to gravity,  $g$ , at Washington. Each experiment produced a number of replicate estimates of  $g$  using the same methodology. Although the basic method remained the same for all experiments, that of the reversible pendulum, there were changes in configuration.

The gravity data frame contains the data from all eight experiments. The grav data frame contains the data from the experiments 7 and 8. The data are expressed as deviations from 980.000 in centimetres per second squared.

**Usage**

gravity

**Format**

This data frame contains the following columns:

g The deviation of the estimate from 980.000 centimetres per second squared.  
series A factor describing from which experiment the estimate was derived.

**Source**

The data were obtained from

Cressie, N. (1982) Playing safe with misweighted means. *Journal of the American Statistical Association*, **77**, 754–759.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

---

hirose

*Failure Time of PET Film*

---

**Description**

The hirose data frame has 44 rows and 3 columns.

PET film is used in electrical insulation. In this accelerated life test the failure times for 44 samples in gas insulated transformers. 4 different voltage levels were used.

**Usage**

hirose

**Format**

This data frame contains the following columns:

volt The voltage (in kV).  
time The failure or censoring time in hours.  
cens The censoring indicator; 1 means right-censored data.

**Source**

The data were obtained from

Hirose, H. (1993) Estimation of threshold stress in accelerated life-testing. *IEEE Transactions on Reliability*, **42**, 650–657.

## Description

Central moment, tail probability, and quantile estimates for a statistic under importance resampling.

## Usage

```
imp.moments(boot.out = NULL, index = 1, t = boot.out$t[, index],
 w = NULL, def = TRUE, q = NULL)
imp.prob(boot.out = NULL, index = 1, t0 = boot.out$t0[index],
 t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
imp.quantile(boot.out = NULL, alpha = NULL, index = 1,
 t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
```

## Arguments

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| boot.out | A object of class "boot" generated by a call to boot or tilt.boot. Use of these functions makes sense only when the bootstrap resampling used unequal weights for the observations. If the importance weights w are not supplied then boot.out is a required argument. It is also required if t is not supplied.                                                                                                                                                           |
| alpha    | The alpha levels for the required quantiles. The default is to calculate the 1%, 2.5%, 5%, 10%, 90%, 95%, 97.5% and 99% quantiles.                                                                                                                                                                                                                                                                                                                                         |
| index    | The index of the variable of interest in the output of boot.out\$statistic. This is not used if the argument t is supplied.                                                                                                                                                                                                                                                                                                                                                |
| t0       | The values at which tail probability estimates are required. For each value t0[i] the function will estimate the bootstrap cdf evaluated at t0[i]. If imp.prob is called without the argument t0 then the bootstrap cdf evaluated at the observed value of the statistic is found.                                                                                                                                                                                         |
| t        | The bootstrap replicates of a statistic. By default these are taken from the bootstrap output object boot.out but they can be supplied separately if required (e.g. when the statistic of interest is a function of the calculated values in boot.out). Either boot.out or t must be supplied.                                                                                                                                                                             |
| w        | The importance resampling weights for the bootstrap replicates. If they are not supplied then boot.out must be supplied, in which case the importance weights are calculated by a call to imp.weights.                                                                                                                                                                                                                                                                     |
| def      | A logical value indicating whether a defensive mixture is to be used for weight calculation. This is used only if w is missing and it is passed unchanged to imp.weights to calculate w.                                                                                                                                                                                                                                                                                   |
| q        | A vector of probabilities specifying the resampling distribution from which any estimates should be found. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations. The estimates depend on this distribution only through the importance weights w so this argument is ignored if w is supplied. If w is missing then q is passed as an argument to imp.weights and used to find w. |

**Value**

A list with the following components :

|       |                                                                                                                                                                                                                                                                                                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| alpha | The alpha levels used for the quantiles, if <code>imp.quantile</code> is used.                                                                                                                                                                                                                                                                                              |
| t0    | The values at which the tail probabilities are estimated, if <code>imp.prob</code> is used.                                                                                                                                                                                                                                                                                 |
| raw   | The raw importance resampling estimates. For <code>imp.moments</code> this has length 2, the first component being the estimate of the mean and the second being the variance estimate. For <code>imp.prob</code> , <code>raw</code> is of the same length as <code>t0</code> , and for <code>imp.quantile</code> it is of the same length as <code>alpha</code> .          |
| rat   | The ratio importance resampling estimates. In this method the weights <code>w</code> are rescaled to have average value one before they are used. The format of this vector is the same as <code>raw</code> .                                                                                                                                                               |
| reg   | The regression importance resampling estimates. In this method the weights which are used are derived from a regression of $t \cdot w$ on <code>w</code> . This choice of weights can be shown to minimize the variance of the weights and also the Euclidean distance of the weights from the uniform weights. The format of this vector is the same as <code>raw</code> . |

 alpha = c(0.9, 0.95, 0.975, 0.99))
as.data.frame(grav.q)

```

---

imp.weights

*Importance Sampling Weights*

---

## Description

This function calculates the importance sampling weight required to correct for simulation from a distribution with probabilities  $p$  when estimates are required assuming that simulation was from an alternative distribution with probabilities  $q$ .

## Usage

```
imp.weights(boot.out, def = TRUE, q = NULL)
```

## Arguments

- |          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| boot.out | A object of class "boot" generated by boot or tilt.boot. Typically the bootstrap simulations would have been done using importance resampling and we wish to do our calculations under the assumption of sampling with equal probabilities.                                                                                                                                                                                                                                                              |
| def      | A logical variable indicating whether the defensive mixture distribution weights should be calculated. This makes sense only in the case where the replicates in boot.out were simulated under a number of different distributions. If this is the case then the defensive mixture weights use a mixture of the distributions used in the bootstrap. The alternative is to calculate the weights for each replicate using knowledge of the distribution from which the bootstrap resample was generated. |
| q        | A vector of probabilities specifying the resampling distribution from which we require inferences to be made. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations and this is the default. q must have length equal to the number of observations in the boot.out\$data and all elements of q must be positive.                                                                                                |

## Details

The importance sampling weight for a bootstrap replicate with frequency vector  $f$  is given by  $\text{prod}((q/p)^f)$ . This reweights the replicates so that estimates can be found as if the bootstrap resamples were generated according to the probabilities  $q$  even though, in fact, they came from the distribution  $p$ .

**Value**

A vector of importance weights of the same length as `boot.out$t`. These weights can then be used to reweight `boot.out$t` so that estimates can be found as if the simulations were from a distribution with probabilities `q`.

**Note**

See the example in the help for `imp.moments` for an example of using `imp.weights`.

---

 inv.logit

*Inverse Logit Function*

---

**Description**

Given a numeric object return the inverse logit of the values.

**Usage**

```
inv.logit(x)
```

**Arguments**

`x`                      A numeric object. Missing values (NAs) are allowed.

**Details**

The inverse logit is defined by  $\exp(x)/(1+\exp(x))$ . Values in `x` of `-Inf` or `Inf` return logits of 0 or 1 respectively. Any NAs in the input will also be NAs in the output.

**Value**

An object of the same type as `x` containing the inverse logits of the input values.

**See Also**

[logit](#), [plogis](#) for which this is a wrapper.

---

islay

*Jura Quartzite Azimuths on Islay*

---

### Description

The islay data frame has 18 rows and 1 columns.

Measurements were taken of paleocurrent azimuths from the Jura Quartzite on the Scottish island of Islay.

### Usage

```
islay
```

### Format

This data frame contains the following column:

theta The angle of the azimuth in degrees East of North.

### Source

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) *A Handbook of Small Data Sets*, Chapman and Hall.

### References

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

Till, R. (1974) *Statistical Methods for the Earth Scientist*. Macmillan.

---

jack.after.boot

*Jackknife-after-Bootstrap Plots*

---

### Description

This function calculates the jackknife influence values from a bootstrap output object and plots the corresponding jackknife-after-bootstrap plot.

### Usage

```
jack.after.boot(boot.out, index = 1, t = NULL, L = NULL,
 useJ = TRUE, stinf = TRUE, alpha = NULL,
 main = "", ylab = NULL, ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | An object of class "boot" which would normally be created by a call to <code>boot</code> . It should represent a nonparametric bootstrap. For reliable results <code>boot.out\$R</code> should be reasonably large.                                                                                                 |
| <code>index</code>    | The index of the statistic of interest in the output of <code>boot.out\$statistic</code> .                                                                                                                                                                                                                          |
| <code>t</code>        | A vector of length <code>boot.out\$R</code> giving the bootstrap replicates of the statistic of interest. This is useful if the statistic of interest is a function of the calculated bootstrap output. If it is not supplied then the default is <code>boot.out\$t[, index]</code> .                               |
| <code>L</code>        | The empirical influence values for the statistic of interest. These are used only if <code>useJ</code> is FALSE. If they are not supplied and are needed, they are calculated by a call to <code>empinf</code> . If <code>L</code> is supplied then it is assumed that they are the infinitesimal jackknife values. |
| <code>useJ</code>     | A logical variable indicating if the jackknife influence values calculated from the bootstrap replicates should be used. If FALSE the empirical influence values are used. The default is TRUE.                                                                                                                     |
| <code>stinf</code>    | A logical variable indicating whether to standardize the jackknife values before plotting them. If TRUE then the jackknife values used are divided by their standard error.                                                                                                                                         |
| <code>alpha</code>    | The quantiles at which the plots are required. The default is <code>c(0.05, 0.1, 0.16, 0.5, 0.84, 0.9, 0.95)</code> .                                                                                                                                                                                               |
| <code>main</code>     | A character string giving the main title for the plot.                                                                                                                                                                                                                                                              |
| <code>ylab</code>     | The label for the Y axis. If the default values of <code>alpha</code> are used and <code>ylab</code> is not supplied then a label indicating which percentiles are plotted is used. If <code>alpha</code> is supplied then the default label will not say which percentiles were used.                              |
| <code>...</code>      | Any extra arguments required by <code>boot.out\$statistic</code> . These are required only if <code>useJ</code> is FALSE and <code>L</code> is not supplied, in which case they are passed to <code>empinf</code> for use in calculation of the empirical influence values.                                         |

**Details**

The centred jackknife quantiles for each observation are estimated from those bootstrap samples in which the particular observation did not appear. These are then plotted against the influence values. If `useJ` is TRUE then the influence values are found in the same way as the difference between the mean of the statistic in the samples excluding the observations and the mean in all samples. If `useJ` is FALSE then empirical influence values are calculated by calling `empinf`.

The resulting plots are useful diagnostic tools for looking at the way individual observations affect the bootstrap output.

The plot will consist of a number of horizontal dotted lines which correspond to the quantiles of the centred bootstrap distribution. For each data point the quantiles of the bootstrap distribution calculated by omitting that point are plotted against the (possibly standardized) jackknife values. The observation number is printed below the plots. To make it easier to see the effect of omitting points on quantiles, the plotted quantiles are joined by line segments. These plots provide a useful diagnostic tool in establishing the effect of individual observations on the bootstrap distribution. See the references below for some guidelines on the interpretation of the plots.

**Value**

There is no returned value but a plot is generated on the current graphics display.

## Side Effects

A plot is created on the current graphics device.

## References

## Examples

```
To draw the jackknife-after-bootstrap plot for the head size data as in
Example 3.24 of Davison and Hinkley (1997)
frets.fun <- function(data, i) {
 pcorr <- function(x) {
 # Function to find the correlations and partial correlations between
 # the four measurements.
 v <- cor(x)
 v.d <- diag(var(x))
 iv <- solve(v)
 iv.d <- sqrt(diag(iv))
 iv <- - diag(1/iv.d) %*% iv %*% diag(1/iv.d)
 q <- NULL
 n <- nrow(v)
 for (i in 1:(n-1))
 q <- rbind(q, c(v[i, 1:i], iv[i,(i+1):n]))
 q <- rbind(q, v[n,])
 diag(q) <- round(diag(q))
 q
 }
 d <- data[i,]
 v <- pcorr(d)
 c(v[1,], v[2,], v[3,], v[4,])
}
frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
we will concentrate on the partial correlation between head breadth
for the first son and head length for the second. This is the 7th
element in the output of frets.fun so we set index = 7
jack.after.boot(frets.boot, useJ = FALSE, stinf = FALSE, index = 7)
```

## Description

Estimates the skewness of a statistic from its empirical influence values.

**Usage**

```
k3.linear(L, strata = NULL)
```

**Arguments**

**L** Vector of the empirical influence values of a statistic. These will usually be calculated by a call to `empinf`.

**strata** A numeric vector or factor specifying which observations (and hence which components of **L**) come from which strata.

**Value**

The skewness estimate calculated from **L**.

**References**

Davison, A. C. and Hinkley, D. V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

**See Also**

[empinf](#), [linear.approx](#), [var.linear](#)

**Examples**

```
To estimate the skewness of the ratio of means for the city data.
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
k3.linear(empinf(data = city, statistic = ratio))
```

---

linear.approx

---

Linear Approximation of Bootstrap Replicates

---

**Description**

This function takes a bootstrap object and for each bootstrap replicate it calculates the linear approximation to the statistic of interest for that bootstrap sample.

**Usage**

```
linear.approx(boot.out, L = NULL, index = 1, type = NULL,
 t0 = NULL, t = NULL, ...)
```

**Arguments**

**boot.out** An object of class "boot" representing a nonparametric bootstrap. It will usually be created by the function `boot`.

**L** A vector containing the empirical influence values for the statistic of interest. If it is not supplied then **L** is calculated through a call to `empinf`.

**index** The index of the variable of interest within the output of `boot.out$statistic`.

|      |                                                                                                                                                                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type | This gives the type of empirical influence values to be calculated. It is not used if L is supplied. The possible types of empirical influence values are described in the help for <a href="#">empinf</a> .                                                                                               |
| t0   | The observed value of the statistic of interest. The input value is used only if one of t or L is also supplied. The default value is <code>boot.out\$t0[index]</code> . If t0 is supplied but neither t nor L are supplied then t0 is set to <code>boot.out\$t0[index]</code> and a warning is generated. |
| t    | A vector of bootstrap replicates of the statistic of interest. If t0 is missing then t is not used, otherwise it is used to calculate the empirical influence values (if they are not supplied in L).                                                                                                      |
| ...  | Any extra arguments required by <code>boot.out\$statistic</code> . These are needed if L is not supplied as they are used by <code>empinf</code> to calculate empirical influence values.                                                                                                                  |

### Details

The linear approximation to a bootstrap replicate with frequency vector `f` is given by  $t_0 + \sum(L * f)/n$  in the one sample with an easy extension to the stratified case. The frequencies are found by calling `boot.array`.

### Value

A vector of length `boot.out$R` with the linear approximations to the statistic of interest for each of the bootstrap samples.

### References

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

### See Also

### Examples

```
Using the city data let us look at the linear approximation to the
ratio statistic and its logarithm. We compare these with the
corresponding plots for the bigcity data

ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
city.boot <- boot(city, ratio, R = 499, stype = "w")
bigcity.boot <- boot(bigcity, ratio, R = 499, stype = "w")
op <- par(pty = "s", mfrow = c(2, 2))

The first plot is for the city data ratio statistic.
city.lin1 <- linear.approx(city.boot)
lim <- range(c(city.boot$t, city.lin1))
plot(city.boot$t, city.lin1, xlim = lim, ylim = lim,
 main = "Ratio; n=10", xlab = "t*", ylab = "tL*")
abline(0, 1)

Now for the log of the ratio statistic for the city data.
city.lin2 <- linear.approx(city.boot, t0 = log(city.boot$t0),
```

```

 t = log(city.boot$t))
lim <- range(c(log(city.boot$t),city.lin2))
plot(log(city.boot$t), city.lin2, xlim = lim, ylim = lim,
 main = "Log(Ratio); n=10", xlab = "t*", ylab = "tL*")
abline(0, 1)

The ratio statistic for the bigcity data.
bigcity.lin1 <- linear.approx(bigcity.boot)
lim <- range(c(bigcity.boot$t,bigcity.lin1))
plot(bigcity.lin1, bigcity.boot$t, xlim = lim, ylim = lim,
 main = "Ratio; n=49", xlab = "t*", ylab = "tL*")
abline(0, 1)

Finally the log of the ratio statistic for the bigcity data.
bigcity.lin2 <- linear.approx(bigcity.boot,t0 = log(bigcity.boot$t0),
 t = log(bigcity.boot$t))
lim <- range(c(log(bigcity.boot$t),bigcity.lin2))
plot(bigcity.lin2, log(bigcity.boot$t), xlim = lim, ylim = lim,
 main = "Log(Ratio); n=49", xlab = "t*", ylab = "tL*")
abline(0, 1)

par(op)

```

---

lines.saddle.distn      *Add a Saddlepoint Approximation to a Plot*

---

## Description

This function adds a line corresponding to a saddlepoint density or distribution function approximation to the current plot.

## Usage

```

S3 method for class 'saddle.distn'
lines(x, dens = TRUE, h = function(u) u, J = function(u) 1,
 npts = 50, lty = 1, ...)

```

## Arguments

|      |                                                                                                                                                                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x    | An object of class "saddle.distn" (see <a href="#">saddle.distn.object</a> representing a saddlepoint approximation to a distribution.                                                                                                                                                                          |
| dens | A logical variable indicating whether the saddlepoint density (TRUE; the default) or the saddlepoint distribution function (FALSE) should be plotted.                                                                                                                                                           |
| h    | Any transformation of the variable that is required. Its first argument must be the value at which the approximation is being performed and the function must be vectorized.                                                                                                                                    |
| J    | When dens=TRUE this function specifies the Jacobian for any transformation that may be necessary. The first argument of J must the value at which the approximation is being performed and the function must be vectorized. If h is supplied J must also be supplied and both must have the same argument list. |
| npts | The number of points to be used for the plot. These points will be evenly spaced over the range of points used in finding the saddlepoint approximation.                                                                                                                                                        |

|     |                                      |
|-----|--------------------------------------|
| lty | The line type to be used.            |
| ... | Any additional arguments to h and J. |

### Details

The function uses `smooth.spline` to produce the saddlepoint curve. When `dens=TRUE` the spline is on the log scale and when `dens=FALSE` it is on the probit scale.

### Value

`sad.d` is returned invisibly.

### Side Effects

A line is added to the current plot.

### References

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

### See Also

[saddle.distn](#)

### Examples

```
In this example we show how a plot such as that in Figure 9.9 of
Davison and Hinkley (1997) may be produced. Note the large number of
bootstrap replicates required in this example.
expdata <- rexp(12)
vfun <- function(d, i) {
 n <- length(d)
 (n-1)/n*var(d[i])
}
exp.boot <- boot(expdata,vfun, R = 9999)
exp.L <- (expdata - mean(expdata))^2 - exp.boot$t0
exp.tL <- linear.approx(exp.boot, L = exp.L)
hist(exp.tL, nclass = 50, probability = TRUE)
exp.t0 <- c(0, sqrt(var(exp.boot$t)))
exp.sp <- saddle.distn(A = exp.L/12, wdist = "n", t0 = exp.t0)

The saddlepoint approximation in this case is to the density of
t-t0 and so t0 must be added for the plot.
lines(exp.sp, h = function(u, t0) u+t0, J = function(u, t0) 1,
 t0 = exp.boot$t0)
```

---

|       |                             |
|-------|-----------------------------|
| logit | <i>Logit of Proportions</i> |
|-------|-----------------------------|

---

**Description**

This function calculates the logit of proportions.

**Usage**

```
logit(p)
```

**Arguments**

**p** A numeric Splus object, all of whose values are in the range [0,1]. Missing values (NAs) are allowed.

**Details**

If any elements of **p** are outside the unit interval then an error message is generated. Values of **p** equal to 0 or 1 (to within machine precision) will return  $-\text{Inf}$  or  $\text{Inf}$  respectively. Any NAs in the input will also be NAs in the output.

**Value**

A numeric object of the same type as **p** containing the logits of the input values.

**See Also**

[inv.logit](#), [qlogis](#) for which this is a wrapper.

---

|        |                                                         |
|--------|---------------------------------------------------------|
| manaus | <i>Average Heights of the Rio Negro river at Manaus</i> |
|--------|---------------------------------------------------------|

---

**Description**

The manaus time series is of class "ts" and has 1080 observations on one variable.

The data values are monthly averages of the daily stages (heights) of the Rio Negro at Manaus. Manaus is 18km upstream from the confluence of the Rio Negro with the Amazon but because of the tiny slope of the water surface and the lower courses of its flatland affluents, they may be regarded as a good approximation of the water level in the Amazon at the confluence. The data here cover 90 years from January 1903 until December 1992.

The Manaus gauge is tied in with an arbitrary bench mark of 100m set in the steps of the Municipal Prefecture; gauge readings are usually referred to sea level, on the basis of a mark on the steps leading to the Parish Church (Matriz), which is assumed to lie at an altitude of 35.874 m according to observations made many years ago under the direction of Samuel Pereira, an engineer in charge of the Manaus Sanitation Committee Whereas such an altitude cannot, by any means, be considered to be a precise datum point, observations have been provisionally referred to it. The measurements are in metres.

## Source

The data were kindly made available by Professors H. O'Reilly Sternberg and D. R. Brillinger of the University of California at Berkeley.

|----------|-----------------------------------------|
| melanoma | <i>Survival from Malignant Melanoma</i> |
|----------|-----------------------------------------|

---

## Description

The melanoma data frame has 205 rows and 7 columns.

The data consist of measurements made on patients with malignant melanoma. Each patient had their tumour removed by surgery at the Department of Plastic Surgery, University Hospital of Odense, Denmark during the period 1962 to 1977. The surgery consisted of complete removal of the tumour together with about 2.5cm of the surrounding skin. Among the measurements taken were the thickness of the tumour and whether it was ulcerated or not. These are thought to be important prognostic variables in that patients with a thick and/or ulcerated tumour have an increased chance of death from melanoma. Patients were followed until the end of 1977.

## Usage

melanoma

## Format

This data frame contains the following columns:

time Survival time in days since the operation, possibly censored.

status The patients status at the end of the study. 1 indicates that they had died from melanoma, 2 indicates that they were still alive and 3 indicates that they had died from causes unrelated to their melanoma.

sex The patients sex; 1=male, 0=female.

age Age in years at the time of the operation.

year Year of operation.

thickness Tumour thickness in mm.

ulcer Indicator of ulceration; 1=present, 0=absent.

## Note

This dataset is not related to the dataset in the **lattice** package with the same name.

motor

*Data from a Simulated Motorcycle Accident*

---

**Description**

The motor data frame has 94 rows and 4 columns. The rows are obtained by removing replicate values of time from the dataset [mcycle](#). Two extra columns are added to allow for strata with a different residual variance in each stratum.

**Usage**

```
motor
```

**Format**

This data frame contains the following columns:

times The time in milliseconds since impact.

accel The recorded head acceleration (in g).

strata A numeric column indicating to which of the three strata (numbered 1, 2 and 3) the observations belong.

v An estimate of the residual variance for the observation. v is constant within the strata but a different estimate is used for each of the three strata.

neuro

*Neurophysiological Point Process Data***Description**

neuro is a matrix containing times of observed firing of a neuron in windows of 250ms either side of the application of a stimulus to a human subject. Each row of the matrix is a replication of the experiment and there were a total of 469 replicates.

**Note**

There are a lot of missing values in the matrix as different numbers of firings were observed in different replicates. The number of firings observed varied from 2 to 6.

**Source**

The data were collected and kindly made available by Dr. S.J. Boniface of the Neurophysiology Unit at the Radcliffe Infirmary, Oxford.

nitrofen

*Toxicity of Nitrofen in Aquatic Systems***Description**

The nitrofen data frame has 50 rows and 5 columns.

Nitrofen is a herbicide that was used extensively for the control of broad-leaved and grass weeds in cereals and rice. Although it is relatively non-toxic to adult mammals, nitrofen is a significant tetragen and mutagen. It is also acutely toxic and reproductively toxic to cladoceran zooplankton. Nitrofen is no longer in commercial use in the U.S., having been the first pesticide to be withdrawn due to tetragenic effects.

The data here come from an experiment to measure the reproductive toxicity of nitrofen on a species of zooplankton (*Ceriodaphnia dubia*). 50 animals were randomized into batches of 10 and each batch was put in a solution with a measured concentration of nitrofen. Then the number of live offspring in each of the three broods to each animal was recorded.

**Usage**

nitrofen

**Format**

This data frame contains the following columns:

conc The nitrofen concentration in the solution (mug/litre).

brood1 The number of live offspring in the first brood.

brood2 The number of live offspring in the second brood.

brood3 The number of live offspring in the third brood.

total The total number of live offspring in the first three broods.

**Source**

The data were obtained from

|-------|---------------------------------------------|
| nodal | <i>Nodal Involvement in Prostate Cancer</i> |
|-------|---------------------------------------------|

---

**Description**

The nodal data frame has 53 rows and 7 columns.

The treatment strategy for a patient diagnosed with cancer of the prostate depend highly on whether the cancer has spread to the surrounding lymph nodes. It is common to operate on the patient to get samples from the nodes which can then be analysed under a microscope but clearly it would be preferable if an accurate assessment of nodal involvement could be made without surgery.

For a sample of 53 prostate cancer patients, a number of possible predictor variables were measured before surgery. The patients then had surgery to determine nodal involvement. It was required to see if nodal involvement could be accurately predicted from the predictor variables and which ones were most important.

**Usage**

nodal

**Format**

This data frame contains the following columns:

m A column of ones.

r An indicator of nodal involvement.

aged The patients age dichotomized into less than 60 (0) and 60 or over 1.

stage A measurement of the size and position of the tumour observed by palpitation with the fingers via the rectum. A value of 1 indicates a more serious case of the cancer.

- grade Another indicator of the seriousness of the cancer, this one is determined by a pathology reading of a biopsy taken by needle before surgery. A value of 1 indicates a more serious case of the cancer.
- xray A third measure of the seriousness of the cancer taken from an X-ray reading. A value of 1 indicates a more serious case of the cancer.
- acid The level of acid phosphatase in the blood serum.

|---------|--------------------------------------------------|
| norm.ci | <i>Normal Approximation Confidence Intervals</i> |
|---------|--------------------------------------------------|

---

Description

Using the normal approximation to a statistic, calculate equi-tailed two-sided confidence intervals.

Usage

```
norm.ci(boot.out = NULL, conf = 0.95, index = 1, var.t0 = NULL,
 t0 = NULL, t = NULL, L = NULL, h = function(t) t,
 hdot = function(t) 1, hinv = function(t) t)
```

Arguments

- |          |                                                                                                                                                                                                                                                               |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| boot.out | A bootstrap output object returned from a call to boot. If t0 is missing then boot.out is a required argument. It is also required if both var.t0 and t are missing.                                                                                          |
| conf     | A scalar or vector containing the confidence level(s) of the required interval(s).                                                                                                                                                                            |
| index    | The index of the statistic of interest within the output of a call to boot.out\$statistic. It is not used if boot.out is missing, in which case t0 must be supplied.                                                                                          |
| var.t0   | The variance of the statistic of interest. If it is not supplied then var(t) is used.                                                                                                                                                                         |
| t0       | The observed value of the statistic of interest. If it is missing then it is taken from boot.out which is required in that case.                                                                                                                              |
| t        | Bootstrap replicates of the variable of interest. These are used to estimate the variance of the statistic of interest if var.t0 is not supplied. The default value is boot.out\$t[,index].                                                                   |
| L        | The empirical influence values for the statistic of interest. These are used to calculate var.t0 if neither var.t0 nor boot.out are supplied. If a transformation is supplied through h then the influence values must be for the untransformed statistic t0. |

|      |                                                                                                                                                                                                                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| h    | A function defining a monotonic transformation, the intervals are calculated on the scale of $h(t)$ and the inverse function $hinv$ is applied to the resulting intervals. $h$ must be a function of one variable only and must be vectorized. The default is the identity function.                    |
| hdot | A function of one argument returning the derivative of $h$ . It is a required argument if $h$ is supplied and is used for approximating the variance of $h(t_0)$ . The default is the constant function 1.                                                                                              |
| hinv | A function, like $h$ , which returns the inverse of $h$ . It is used to transform the intervals calculated on the scale of $h(t)$ back to the original scale. The default is the identity function. If $h$ is supplied but $hinv$ is not, then the intervals returned will be on the transformed scale. |

### Details

It is assumed that the statistic of interest has an approximately normal distribution with variance  $var.t_0$  and so a confidence interval of length  $2 \cdot qnorm((1+conf)/2) \cdot \sqrt{var.t_0}$  is found. If `boot.out` or `t` are supplied then the interval is bias-corrected using the bootstrap bias estimate, and so the interval would be centred at  $2 \cdot t_0 - \text{mean}(t)$ . Otherwise the interval is centred at  $t_0$ .

### Value

If `length(conf)` is 1 then a vector containing the confidence level and the endpoints of the interval is returned. Otherwise, the returned value is a matrix where each row corresponds to a different confidence level.

### Note

This function is primarily designed to be called by `boot.ci` to calculate the normal approximation after a bootstrap but it can also be used without doing any bootstrap calculations as long as `t_0` and `var.t_0` can be supplied. See the examples below.

### Examples

```
In Example 5.1 of Davison and Hinkley (1997), normal approximation
confidence intervals are found for the air-conditioning data.
air.mean <- mean(aircondit$hours)
air.n <- nrow(aircondit)
air.v <- air.mean^2/air.n
norm.ci(t0 = air.mean, var.t0 = air.v)
exp(norm.ci(t0 = log(air.mean), var.t0 = 1/air.n)[2:3])

Now a more complicated example - the ratio estimate for the city data.
ratio <- function(d, w)
 sum(d$x * w)/sum(d$u * w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
norm.ci(t0 = ratio(city,rep(0.1,10)), var.t0 = city.v)
```

nuclear

*Nuclear Power Station Construction Data***Description**

The nuclear data frame has 32 rows and 11 columns.

The data relate to the construction of 32 light water reactor (LWR) plants constructed in the U.S.A in the late 1960's and early 1970's. The data was collected with the aim of predicting the cost of construction of further LWR plants. 6 of the power plants had partial turnkey guarantees and it is possible that, for these plants, some manufacturers' subsidies may be hidden in the quoted capital costs.

**Usage**

nuclear

**Format**

This data frame contains the following columns:

cost The capital cost of construction in millions of dollars adjusted to 1976 base.

date The date on which the construction permit was issued. The data are measured in years since January 1 1990 to the nearest month.

t1 The time between application for and issue of the construction permit.

t2 The time between issue of operating license and construction permit.

cap The net capacity of the power plant (MWe).

pr A binary variable where 1 indicates the prior existence of a LWR plant at the same site.

ne A binary variable where 1 indicates that the plant was constructed in the north-east region of the U.S.A.

ct A binary variable where 1 indicates the use of a cooling tower in the plant.

bw A binary variable where 1 indicates that the nuclear steam supply system was manufactured by Babcock-Wilcox.

cum.n The cumulative number of power plants constructed by each architect-engineer.

pt A binary variable where 1 indicates those plants with partial turnkey guarantees.

**Source**

The data were obtained from

Cox, D.R. and Snell, E.J. (1981) *Applied Statistics: Principles and Examples*. Chapman and Hall.

**References**

paulsen

*Neurotransmission in Guinea Pig Brains***Description**

The paulsen data frame has 346 rows and 1 columns.

Sections were prepared from the brain of adult guinea pigs. Spontaneous currents that flowed into individual brain cells were then recorded and the peak amplitude of each current measured. The aim of the experiment was to see if the current flow was quantal in nature (i.e. that it is not a single burst but instead is built up of many smaller bursts of current). If the current was indeed quantal then it would be expected that the distribution of the current amplitude would be multimodal with modes at regular intervals. The modes would be expected to decrease in magnitude for higher current amplitudes.

**Usage**

```
paulsen
```

**Format**

This data frame contains the following column:

y The current flowing into individual brain cells. The currents are measured in pico-amperes.

**Source**

The data were kindly made available by Dr. O. Paulsen from the Department of Pharmacology at the University of Oxford.

Paulsen, O. and Heggelund, P. (1994) The quantal size at retinogeniculate synapses determined from spontaneous and evoked EPSCs in guinea-pig thalamic slices. *Journal of Physiology*, **480**, 505–511.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

plot.boot

*Plots of the Output of a Bootstrap Simulation***Description**

This takes a bootstrap object and produces plots for the bootstrap replicates of the variable of interest.

**Usage**

```
S3 method for class 'boot'
plot(x, index = 1, t0 = NULL, t = NULL, jack = FALSE,
 qdist = "norm", nclass = NULL, df, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | An object of class "boot" returned from one of the bootstrap generation functions.                                                                                                                                                                      |
| <code>index</code>  | The index of the variable of interest within the output of <code>boot.out</code> . This is ignored if <code>t</code> and <code>t0</code> are supplied.                                                                                                  |
| <code>t0</code>     | The original value of the statistic. This defaults to <code>boot.out\$t0[index]</code> unless <code>t</code> is supplied when it defaults to NULL. In that case no vertical line is drawn on the histogram.                                             |
| <code>t</code>      | The bootstrap replicates of the statistic. Usually this will take on its default value of <code>boot.out\$t[, index]</code> , however it may be useful sometimes to supply a different set of values which are a function of <code>boot.out\$t</code> . |
| <code>jack</code>   | A logical value indicating whether a jackknife-after-bootstrap plot is required. The default is not to produce such a plot.                                                                                                                             |
| <code>qdist</code>  | The distribution against which the Q-Q plot should be drawn. At present "norm" (normal distribution - the default) and "chisq" (chi-squared distribution) are the only possible values.                                                                 |
| <code>nclass</code> | An integer giving the number of classes to be used in the bootstrap histogram. The default is the integer between 10 and 100 closest to <code>ceiling(length(t)/25)</code> .                                                                            |
| <code>df</code>     | If <code>qdist</code> is "chisq" then this is the degrees of freedom for the chi-squared distribution to be used. It is a required argument in that case.                                                                                               |
| <code>...</code>    | When <code>jack</code> is TRUE additional parameters to <code>jack.after.boot</code> can be supplied. See the help file for <code>jack.after.boot</code> for details of the possible parameters.                                                        |

**Details**

This function will generally produce two side-by-side plots. The left plot will be a histogram of the bootstrap replicates. Usually the breaks of the histogram will be chosen so that `t0` is at a breakpoint and all intervals are of equal length. A vertical dotted line indicates the position of `t0`. This cannot be done if `t` is supplied but `t0` is not and so, in that case, the breakpoints are computed by `hist` using the `nclass` argument and no vertical line is drawn.

The second plot is a Q-Q plot of the bootstrap replicates. The order statistics of the replicates can be plotted against normal or chi-squared quantiles. In either case the expected line is also plotted. For the normal, this will have intercept `mean(t)` and slope `sqrt(var(t))` while for the chi-squared it has intercept 0 and slope 1.

If `jack` is TRUE a third plot is produced beneath these two. That plot is the jackknife-after-bootstrap plot. This plot may only be requested when nonparametric simulation has been used. See `jack.after.boot` for further details of this plot.

**Value**

`boot.out` is returned invisibly.

**Side Effects**

All screens are closed and cleared and a number of plots are produced on the current graphics device. Screens are closed but not cleared at termination of this function.

**See Also**

[boot](#), [jack.after.boot](#), [print.boot](#)

**Examples**

```

We fit an exponential model to the air-conditioning data and use
that for a parametric bootstrap. Then we look at plots of the
resampled means.
air.rg <- function(data, mle) rexp(length(data), 1/mle)

air.boot <- boot(aircondit$hours, mean, R = 999, sim = "parametric",
 ran.gen = air.rg, mle = mean(aircondit$hours))
plot(air.boot)

In the difference of means example for the last two series of the
gravity data
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7,]
grav.fun <- function(dat, w) {
 strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
 d <- dat[, 1]
 ns <- tabulate(strata)
 w <- w/tapply(w, strata, sum)[strata]
 mns <- as.vector(tapply(d * w, strata, sum)) # drop names
 mn2 <- tapply(d * d * w, strata, sum)
 s2hat <- sum((mn2 - mns^2)/ns)
 c(mns[2] - mns[1], s2hat)
}

grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w", strata = grav1[, 2])
plot(grav.boot)
now suppose we want to look at the studentized differences.
grav.z <- (grav.boot$t[, 1]-grav.boot$t0[1])/sqrt(grav.boot$t[, 2])
plot(grav.boot, t = grav.z, t0 = 0)

In this example we look at the one of the partial correlations for the
head dimensions in the dataset frets.
frets.fun <- function(data, i) {
 pcorr <- function(x) {
 # Function to find the correlations and partial correlations between
 # the four measurements.
 v <- cor(x)
 v.d <- diag(var(x))
 iv <- solve(v)
 iv.d <- sqrt(diag(iv))
 iv <- - diag(1/iv.d) %*% iv %*% diag(1/iv.d)
 q <- NULL
 n <- nrow(v)
 for (i in 1:(n-1))
 q <- rbind(q, c(v[i, 1:i], iv[i,(i+1):n]))
 q <- rbind(q, v[n,])
 diag(q) <- round(diag(q))
 q
 }
 d <- data[i,]
 v <- pcorr(d)
 c(v[1,], v[2,], v[3,], v[4,])
}

frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
plot(frets.boot, index = 7, jack = TRUE, stinf = FALSE, useJ = FALSE)

```

---

poisons

*Animal Survival Times*

---

### Description

The poisons data frame has 48 rows and 3 columns.

The data form a 3x4 factorial experiment, the factors being three poisons and four treatments. Each combination of the two factors was used for four animals, the allocation to animals having been completely randomized.

### Usage

poisons

### Format

This data frame contains the following columns:

time The survival time of the animal in units of 10 hours.

poison A factor with levels 1, 2 and 3 giving the type of poison used.

treat A factor with levels A, B, C and D giving the treatment.

### Source

The data were obtained from

Box, G.E.P. and Cox, D.R. (1964) An analysis of transformations (with Discussion). *Journal of the Royal Statistical Society, B*, **26**, 211–252.

### References

---

polar

*Pole Positions of New Caledonian Laterites*

---

### Description

The polar data frame has 50 rows and 2 columns.

The data are the pole positions from a paleomagnetic study of New Caledonian laterites.

### Usage

polar

### Format

This data frame contains the following columns:

- lat The latitude (in degrees) of the pole position. Note that all latitudes are negative as the axis is taken to be in the lower hemisphere.
- long The longitude (in degrees) of the pole position.

### Source

The data were obtained from

Fisher, N.I., Lewis, T. and Embleton, B.J.J. (1987) *Statistical Analysis of Spherical Data*. Cambridge University Press.

### References

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

---

|            |                                              |
|------------|----------------------------------------------|
| print.boot | <i>Print a Summary of a Bootstrap Object</i> |
|------------|----------------------------------------------|

---

### Description

This is a method for the function `print()` for objects of the class "boot" created by a call to `boot`, `censboot`, `tilt.boot` or `tsboot`.

### Usage

```
S3 method for class 'boot'
print(x, digits = getOption("digits"),
 index = 1:ncol(boot.out$t), ...)
```

### Arguments

- x A bootstrap output object of class "boot" generated by one of the bootstrap functions.
- digits The number of digits to be printed in the summary statistics.
- index Indices indicating for which elements of the bootstrap output summary statistics are required.
- ... further arguments passed to or from other methods.

### Details

For each statistic calculated in the bootstrap the original value and the bootstrap estimates of its bias and standard error are printed. If `boot.out$t0` is missing (such as when it was created by a call to `tsboot` with `orig.t = FALSE`) the bootstrap mean and standard error are printed. If resampling was done using importance resampling weights, then the bootstrap estimates are reweighted as if uniform resampling had been done. The ratio importance sampling estimates are used and if there were a number of distributions then defensive mixture distributions are used. In this case an extra column with the mean of the observed bootstrap statistics is also printed.

**Value**

The bootstrap object is returned invisibly.

**See Also**

---

print.bootci

*Print Bootstrap Confidence Intervals*

---

**Description**

This is a method for the function `print()` to print objects of the class "bootci".

**Usage**

```
S3 method for class 'bootci'
print(x, hinv = NULL, ...)
```

**Arguments**

|                   |                                                                                 |
|-------------------|---------------------------------------------------------------------------------|
| <code>x</code>    | The output from a call to <code>boot.ci</code> .                                |
| <code>hinv</code> | A transformation to be made to the interval end-points before they are printed. |
| <code>...</code>  | further arguments passed to or from other methods.                              |

**Details**

This function prints out the results from `boot.ci` in a "nice" format. It also notes whether the scale of the intervals is the original scale of the input to `boot.ci` or a different scale and whether the calculations were done on a transformed scale. It also looks at the order statistics that were used in calculating the intervals. If the smallest or largest values were used then it prints a message

Warning : Intervals used Extreme Quantiles

Such intervals should be considered very unstable and not relied upon for inferences. Even if the extreme values are not used, it is possible that the intervals are unstable if they used quantiles close to the extreme values. The function alerts the user to intervals which use the upper or lower 10 order statistics with the message

Some intervals may be unstable

**Value**

The object `ci.out` is returned invisibly.

**See Also**

### Description

This is a method for the function `print()` to print objects of class `"saddle.distn"`.

### Usage

```
S3 method for class 'saddle.distn'
print(x, ...)
```

### Arguments

|     |                                                                                                 |
|-----|-------------------------------------------------------------------------------------------------|
| x   | An object of class <code>"saddle.distn"</code> created by a call to <code>saddle.distn</code> . |
| ... | further arguments passed to or from other methods.                                              |

### Details

The quantiles of the saddlepoint approximation to the distribution are printed along with the original call and some other useful information.

### Value

The input is returned invisibly.

|               |                                                     |
|---------------|-----------------------------------------------------|
| print.simplex | <i>Print Solution to Linear Programming Problem</i> |
|---------------|-----------------------------------------------------|

---

### Description

This is a method for the function `print()` to print objects of class `"simplex"`.

### Usage

```
S3 method for class 'simplex'
print(x, ...)
```

### Arguments

|     |                                                                                                                                       |
|-----|---------------------------------------------------------------------------------------------------------------------------------------|
| x   | An object of class <code>"simplex"</code> created by calling the function <code>simplex</code> to solve a linear programming problem. |
| ... | further arguments passed to or from other methods.                                                                                    |

**Details**

The coefficients of the objective function are printed. If a solution to the linear programming problem was found then the solution and the optimal value of the objective function are printed. If a feasible solution was found but the maximum number of iterations was exceeded then the last feasible solution and the objective function value at that point are printed. If no feasible solution could be found then a message stating that is printed.

**Value**

x is returned silently.

|-----------|-------------------------------------------|
| remission | <i>Cancer Remission and Cell Activity</i> |
|-----------|-------------------------------------------|

---

**Description**

The remission data frame has 27 rows and 3 columns.

**Usage**

```
remission
```

**Format**

This data frame contains the following columns:

- LI A measure of cell activity.
- m The number of patients in each group (all values are actually 1 here).
- r The number of patients (out of m) who went into remission.

**Source**

The data were obtained from  
Freeman, D.H. (1987) *Applied Categorical Data Analysis*. Marcel Dekker.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

**Description**

This function calculates a saddlepoint approximation to the distribution of a linear combination of  $\mathbf{W}$  at a particular point  $u$ , where  $\mathbf{W}$  is a vector of random variables. The distribution of  $\mathbf{W}$  may be multinomial (default), Poisson or binary. Other distributions are possible also if the adjusted cumulant generating function and its second derivative are given. Conditional saddlepoint approximations to the distribution of one linear combination given the values of other linear combinations of  $\mathbf{W}$  can be calculated for  $\mathbf{W}$  having binary or Poisson distributions.

**Usage**

```
saddle(A = NULL, u = NULL, wdist = "m", type = "simp", d = NULL,
 d1 = 1, init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
 strata = NULL, K.adj = NULL, K2 = NULL)
```

**Arguments**

|               |                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>A</b>      | A vector or matrix of known coefficients of the linear combinations of $\mathbf{W}$ . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored.                                                                                                                                                                                                                   |
| <b>u</b>      | The value at which it is desired to calculate the saddlepoint approximation to the distribution of the linear combination of $\mathbf{W}$ . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored.                                                                                                                                                             |
| <b>wdist</b>  | The distribution of $\mathbf{W}$ . This can be one of "m" (multinomial), "p" (Poisson), "b" (binary) or "o" (other). If <code>K.adj</code> and <code>K2</code> are given <code>wdist</code> is set to "o".                                                                                                                                                                                                                 |
| <b>type</b>   | The type of saddlepoint approximation. Possible types are "simp" for simple saddlepoint and "cond" for the conditional saddlepoint. When <code>wdist</code> is "o" or "m", <code>type</code> is automatically set to "simp", which is the only type of saddlepoint currently implemented for those distributions.                                                                                                          |
| <b>d</b>      | This specifies the dimension of the whole statistic. This argument is required only when <code>wdist</code> = "o" and defaults to 1 if not supplied in that case. For other distributions it is set to <code>ncol(A)</code> .                                                                                                                                                                                              |
| <b>d1</b>     | When <code>type</code> is "cond" this is the dimension of the statistic of interest which must be less than <code>length(u)</code> . Then the saddlepoint approximation to the conditional distribution of the first <code>d1</code> linear combinations given the values of the remaining combinations is found. Conditional distribution function approximations can only be found if the value of <code>d1</code> is 1. |
| <b>init</b>   | Used if <code>wdist</code> is either "m" or "o", this gives initial values to <code>nlmin</code> which is used to solve the saddlepoint equation.                                                                                                                                                                                                                                                                          |
| <b>mu</b>     | The values of the parameters of the distribution of $\mathbf{W}$ when <code>wdist</code> is "m", "p" or "b". <code>mu</code> must be of the same length as $\mathbf{W}$ (i.e. <code>nrow(A)</code> ). The default is that all values of <code>mu</code> are equal and so the elements of $\mathbf{W}$ are identically distributed.                                                                                         |
| <b>LR</b>     | If TRUE then the Lugananni-Rice approximation to the cdf is used, otherwise the approximation used is based on Barndorff-Nielsen's $r^*$ .                                                                                                                                                                                                                                                                                 |
| <b>strata</b> | The strata for stratified data.                                                                                                                                                                                                                                                                                                                                                                                            |

|       |                                                                                                                                                                                                                                                                                                                                                              |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| K.adj | The adjusted cumulant generating function used when wdist is "o". This is a function of a single parameter, zeta, which calculates $K(\text{zeta}) - u * \text{zeta}$ , where $K(\text{zeta})$ is the cumulant generating function of $\mathbf{W}$ .                                                                                                         |
| K2    | This is a function of a single parameter zeta which returns the matrix of second derivatives of $K(\text{zeta})$ for use when wdist is "o". If K.adj is given then this must be given also. It is called only once with the calculated solution to the saddlepoint equation being passed as the argument. This argument is ignored if K.adj is not supplied. |

### Details

If wdist is "o" or "m", the saddlepoint equations are solved using `nlmin` to minimize `K.adj` with respect to its parameter `zeta`. For the Poisson and binary cases, a generalized linear model is fitted such that the parameter estimates solve the saddlepoint equations. The response variable 'y' for the `glm` must satisfy the equation  $t(A) \%*\% y = u$  ( $t()$  being the transpose function). Such a vector can be found as a feasible solution to a linear programming problem. This is done by a call to `simplex`. The covariate matrix for the `glm` is given by `A`.

### Value

A list consisting of the following components

|           |                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| spa       | The saddlepoint approximations. The first value is the density approximation and the second value is the distribution function approximation.       |
| zeta.hat  | The solution to the saddlepoint equation. For the conditional saddlepoint this is the solution to the saddlepoint equation for the numerator.       |
| zeta2.hat | If type is "cond" this is the solution to the saddlepoint equation for the denominator. This component is not returned for any other value of type. |

### Examples

```
To evaluate the bootstrap distribution of the mean failure time of
air-conditioning equipment at 80 hours
saddle(A = aircondit$hours/12, u = 80)

Alternatively this can be done using a conditional poisson
saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
```

```

wdist = "p", type = "cond")

To use the Lugananni-Rice approximation to this
saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
 wdist = "p", type = "cond",
 LR = TRUE)

Example 9.16 of Davison and Hinkley (1997) calculates saddlepoint
approximations to the distribution of the ratio statistic for the
city data. Since the statistic is not in itself a linear combination
of random Variables, its distribution cannot be found directly.
Instead the statistic is expressed as the solution to a linear
estimating equation and hence its distribution can be found. We
get the saddlepoint approximation to the pdf and cdf evaluated at
t = 1.25 as follows.
jacobian <- function(dat,t,zeta)
{
 p <- exp(zeta*(dat$x-t*dat$u))
 abs(sum(dat$u*p)/sum(p))
}
city.sp1 <- saddle(A = city$x-1.25*city$u, u = 0)
city.sp1$spa[1] <- jacobian(city, 1.25, city.sp1$zeta.hat) * city.sp1$spa[1]
city.sp1

```

*Saddlepoint Distribution Approximations for Bootstrap Statistics*

## Description

Approximate an entire distribution using saddlepoint methods. This function can calculate simple and conditional saddlepoint distribution approximations for a univariate quantity of interest. For the simple saddlepoint the quantity of interest is a linear combination of  $\mathbf{W}$  where  $\mathbf{W}$  is a vector of random variables. For the conditional saddlepoint we require the distribution of one linear combination given the values of any number of other linear combinations. The distribution of  $\mathbf{W}$  must be one of multinomial, Poisson or binary. The primary use of this function is to calculate quantiles of bootstrap distributions using saddlepoint approximations. Such quantiles are required by the function [control](#) to approximate the distribution of the linear approximation to a statistic.

## Usage

```

saddle.distn(A, u = NULL, alpha = NULL, wdist = "m",
 type = "simp", npts = 20, t = NULL, t0 = NULL,
 init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
 strata = NULL, ...)

```

## Arguments

**A** This is a matrix of known coefficients or a function which returns such a matrix. If a function then its first argument must be the point  $t$  at which a saddlepoint is required. The most common reason for  $A$  being a function would be if the statistic is not itself a linear combination of the  $\mathbf{W}$  but is the solution to a linear estimating equation.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>u</code>      | If <code>A</code> is a function then <code>u</code> must also be a function returning a vector with length equal to the number of columns of the matrix returned by <code>A</code> . Usually all components other than the first will be constants as the other components are the values of the conditioning variables. If <code>A</code> is a matrix with more than one column (such as when <code>wdist = "cond"</code> ) then <code>u</code> should be a vector with length one less than <code>ncol(A)</code> . In this case <code>u</code> specifies the values of the conditioning variables. If <code>A</code> is a matrix with one column or a vector then <code>u</code> is not used.                                 |
| <code>alpha</code>  | The alpha levels for the quantiles of the distribution which should be returned. By default the 0.1, 0.5, 1, 2.5, 5, 10, 20, 50, 80, 90, 95, 97.5, 99, 99.5 and 99.9 percentiles are calculated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>wdist</code>  | The distribution of <b>W</b> . Possible values are "m" (multinomial), "p" (Poisson), or "b" (binary).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>type</code>   | The type of saddlepoint to be used. Possible values are "simp" (simple saddlepoint) and "cond" (conditional). If <code>wdist</code> is "m", <code>type</code> is set to "simp".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>npts</code>   | The number of points at which the saddlepoint approximation should be calculated and then used to fit the spline.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>t</code>      | A vector of points at which the saddlepoint approximations are calculated. These points should extend beyond the extreme quantiles required but still be in the possible range of the bootstrap distribution. The observed value of the statistic should not be included in <code>t</code> as the distribution function approximation breaks down at that point. The points should, however cover the entire effective range of the distribution including close to the centre. If <code>t</code> is supplied then <code>npts</code> is set to <code>length(t)</code> . When <code>t</code> is not supplied, the function attempts to find the effective range of the distribution and then selects points to cover this range. |
| <code>t0</code>     | If <code>t</code> is not supplied then a vector of length 2 should be passed as <code>t0</code> . The first component of <code>t0</code> should be the centre of the distribution and the second should be an estimate of spread (such as a standard error). These two are then used to find the effective range of the distribution. The range finding mechanism does rely on an accurate estimate of location in <code>t0[1]</code> .                                                                                                                                                                                                                                                                                         |
| <code>init</code>   | When <code>wdist</code> is "m", this vector should contain the initial values to be passed to <code>nlmin</code> when it is called to solve the saddlepoint equations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>mu</code>     | The vector of parameter values for the distribution. The default is that the components of <b>W</b> are identically distributed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>LR</code>     | A logical flag. When <code>LR</code> is TRUE the Lugananni-Rice cdf approximations are calculated and used to fit the spline. Otherwise the cdf approximations used are based on Barndorff-Nielsen's $r^*$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>strata</code> | A vector giving the strata when the rows of <code>A</code> relate to stratified data. This is used only when <code>wdist</code> is "m".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>    | When <code>A</code> and <code>u</code> are functions any additional arguments are passed unchanged each time one of them is called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Details

The range at which the saddlepoint is used is such that the cdf approximation at the endpoints is more extreme than required by the extreme values of `alpha`. The lower endpoint is found by evaluating the saddlepoint at the points `t0[1]-2*t0[2]`, `t0[1]-4*t0[2]`, `t0[1]-8*t0[2]` etc. until a point is found with a cdf approximation less than  $\min(\alpha)/10$ , then a bisection method is used to find the endpoint which has cdf approximation in the range  $(\min(\alpha)/1000, \min(\alpha)/10)$ . Then a number of, equally spaced, points are chosen between the lower endpoint and `t0[1]` until

a total of  $npts/2$  approximations have been made. The remaining  $npts/2$  points are chosen to the right of  $t0[1]$  in a similar manner. Any points which are very close to the centre of the distribution are then omitted as the cdf approximations are not reliable at the centre. A smoothing spline is then fitted to the probit of the saddlepoint distribution function approximations at the remaining points and the required quantiles are predicted from the spline.

Sometimes the function will terminate with the message "Unable to find range". There are two main reasons why this may occur. One is that the distribution is too discrete and/or the required quantiles too extreme, this can cause the function to be unable to find a point within the allowable range which is beyond the extreme quantiles. Another possibility is that the value of  $t0[2]$  is too small and so too many steps are required to find the range. The first problem cannot be solved except by asking for less extreme quantiles, although for very discrete distributions the approximations may not be very good. In the second case using a larger value of  $t0[2]$  will usually solve the problem.

### Value

The returned value is an object of class "saddle.distn". See the help file for [saddle.distn.object](#) for a description of such an object.

### Examples

```
The bootstrap distribution of the mean of the air-conditioning
failure data: fails to find value on R (and probably on S too)
air.t0 <- c(mean(aircondit$hours), sqrt(var(aircondit$hours)/12))
Not run: saddle.distn(A = aircondit$hours/12, t0 = air.t0)

alternatively using the conditional poisson
saddle.distn(A = cbind(aircondit$hours/12, 1), u = 12, wdist = "p",
 type = "cond", t0 = air.t0)

Distribution of the ratio of a sample of size 10 from the bigcity
data, taken from Example 9.16 of Davison and Hinkley (1997).
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
bigcity.t0 <- c(mean(bigcity$x)/mean(bigcity$u), sqrt(city.v))
Afn <- function(t, data) cbind(data$x - t*data$u, 1)
ufn <- function(t, data) c(0,10)
saddle.distn(A = Afn, u = ufn, wdist = "b", type = "cond",
 t0 = bigcity.t0, data = bigcity)
```

```
From Example 9.16 of Davison and Hinkley (1997) again, we find the
conditional distribution of the ratio given the sum of city$u.
Afn <- function(t, data) cbind(data$x-t*data$u, data$u, 1)
ufn <- function(t, data) c(0, sum(data$u), 10)
city.t0 <- c(mean(city$x)/mean(city$u), sqrt(city.v))
saddle.distn(A = Afn, u = ufn, wdist = "p", type = "cond", t0 = city.t0,
 data = city)
```

---

saddle.distn.object      *Saddlepoint Distribution Approximation Objects*

---

## Description

Class of objects that result from calculating saddlepoint distribution approximations by a call to `saddle.distn`.

## Generation

This class of objects is returned from calls to the function `saddle.distn`.

## Methods

The class "saddle.distn" has methods for the functions `lines` and `print`.

## Structure

Objects of class "saddle.distn" are implemented as a list with the following components.

**quantiles** A matrix with 2 columns. The first column contains the probabilities alpha and the second column contains the estimated quantiles of the distribution at those probabilities derived from the spline.

**points** A matrix of evaluations of the saddlepoint approximation. The first column contains the values of t which were used, the second and third contain the density and cdf approximations at those points and the rest of the columns contain the solutions to the saddlepoint equations. When type is "simp", there is only one of those. When type is "cond" there are 2\*d-1 where d is the number of columns in A or the output of  $A(t, \dots \{ \})$ . The first d of these correspond to the numerator and the remainder correspond to the denominator.

**distn** An object of class `smooth.spline`. This corresponds to the spline fitted to the saddlepoint cdf approximations in points in order to approximate the entire distribution. For the structure of the object see `smooth.spline`.

**call** The original call to `saddle.distn` which generated the object.

**LR** A logical variable indicating whether the Lugananni-Rice approximations were used.

salinity

*Water Salinity and River Discharge***Description**

The salinity data frame has 28 rows and 4 columns.

Biweekly averages of the water salinity and river discharge in Pamlico Sound, North Carolina were recorded between the years 1972 and 1977. The data in this set consists only of those measurements in March, April and May.

**Usage**

```
salinity
```

**Format**

This data frame contains the following columns:

sal The average salinity of the water over two weeks.

lag The average salinity of the water lagged two weeks. Since only spring is used, the value of lag is not always equal to the previous value of sal.

trend A factor indicating in which of the 6 biweekly periods between March and May, the observations were taken. The levels of the factor are from 0 to 5 with 0 being the first two weeks in March.

dis The amount of river discharge during the two weeks for which sal is the average salinity.

**Source**

The data were obtained from

Ruppert, D. and Carroll, R.J. (1980) Trimmed least squares estimation in the linear model. *Journal of the American Statistical Association*, **75**, 828–838.

**References**

simplex

*Simplex Method for Linear Programming Problems***Description**

This function will optimize the linear function  $a\%*x$  subject to the constraints  $A1\%*x \leq b1$ ,  $A2\%*x \geq b2$ ,  $A3\%*x = b3$  and  $x \geq 0$ . Either maximization or minimization is possible but the default is minimization.

**Usage**

```
simplex(a, A1 = NULL, b1 = NULL, A2 = NULL, b2 = NULL, A3 = NULL,
 b3 = NULL, maxi = FALSE, n.iter = n + 2 * m, eps = 1e-10)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>a</code>      | A vector of length <code>n</code> which gives the coefficients of the objective function.                                                                                                                                                                                                                                     |
| <code>A1</code>     | An <code>m1</code> by <code>n</code> matrix of coefficients for the $\leq$ type of constraints.                                                                                                                                                                                                                               |
| <code>b1</code>     | A vector of length <code>m1</code> giving the right hand side of the $\leq$ constraints. This argument is required if <code>A1</code> is given and ignored otherwise. All values in <code>b1</code> must be non-negative.                                                                                                     |
| <code>A2</code>     | An <code>m2</code> by <code>n</code> matrix of coefficients for the $\geq$ type of constraints.                                                                                                                                                                                                                               |
| <code>b2</code>     | A vector of length <code>m2</code> giving the right hand side of the $\geq$ constraints. This argument is required if <code>A2</code> is given and ignored otherwise. All values in <code>b2</code> must be non-negative. Note that the constraints $x \geq 0$ are included automatically and so should not be repeated here. |
| <code>A3</code>     | An <code>m3</code> by <code>n</code> matrix of coefficients for the equality constraints.                                                                                                                                                                                                                                     |
| <code>b3</code>     | A vector of length <code>m3</code> giving the right hand side of equality constraints. This argument is required if <code>A3</code> is given and ignored otherwise. All values in <code>b3</code> must be non-negative.                                                                                                       |
| <code>maxi</code>   | A logical flag which specifies minimization if <code>FALSE</code> (default) and maximization otherwise. If <code>maxi</code> is <code>TRUE</code> then the maximization problem is recast as a minimization problem by changing the objective function coefficients to their negatives.                                       |
| <code>n.iter</code> | The maximum number of iterations to be conducted in each phase of the simplex method. The default is <code>n+2*(m1+m2+m3)</code> .                                                                                                                                                                                            |
| <code>eps</code>    | The floating point tolerance to be used in tests of equality.                                                                                                                                                                                                                                                                 |

**Details**

The method employed by this function is the two phase tableau simplex method. If there are  $\geq$  or equality constraints an initial feasible solution is not easy to find. To find a feasible solution an artificial variable is introduced into each  $\geq$  or equality constraint and an auxiliary objective function is defined as the sum of these artificial variables. If a feasible solution to the set of constraints exists then the auxiliary objective will be minimized when all of the artificial variables are 0. These are then discarded and the original problem solved starting at the solution to the auxiliary problem. If the only constraints are of the  $\leq$  form, the origin is a feasible solution and so the first stage can be omitted.

**Value**

An object of class "simplex": see [simplex.object](#).

**Note**

The method employed here is suitable only for relatively small systems. Also if possible the number of constraints should be reduced to a minimum in order to speed up the execution time which is approximately proportional to the cube of the number of constraints. In particular if there are any constraints of the form  $x[i] \geq b2[i]$  they should be omitted by setting  $x[i] = x[i] - b2[i]$ , changing all the constraints and the objective function accordingly and then transforming back after the solution has been found.

## Examples

```
This example is taken from Exercise 7.5 of Gill, Murray and Wright (1991).
enj <- c(200, 6000, 3000, -200)
fat <- c(800, 6000, 1000, 400)
vitx <- c(50, 3, 150, 100)
vity <- c(10, 10, 75, 100)
vitz <- c(150, 35, 75, 5)
simplex(a = enj, A1 = fat, b1 = 13800, A2 = rbind(vitx, vity, vitz),
 b2 = c(600, 300, 550), maxi = TRUE)
```

---

simplex.object

*Linear Programming Solution Objects*

---

## Description

Class of objects that result from solving a linear programming problem using simplex.

## Generation

This class of objects is returned from calls to the function `simplex`.

## Methods

The class "saddle.distn" has a method for the function `print`.

## Structure

Objects of class "simplex" are implemented as a list with the following components.

**soln** The values of  $x$  which optimize the objective function under the specified constraints provided those constraints are jointly feasible.

**solved** This indicates whether the problem was solved. A value of  $-1$  indicates that no feasible solution could be found. A value of  $0$  that the maximum number of iterations was reached without termination of the second stage. This may indicate an unbounded function or simply that more iterations are needed. A value of  $1$  indicates that an optimal solution has been found.

**value** The value of the objective function at `soln`.

**val.aux** This is `NULL` if a feasible solution is found. Otherwise it is a positive value giving the value of the auxiliary objective function when it was minimized.

**obj** The original coefficients of the objective function.

**a** The objective function coefficients re-expressed such that the basic variables have coefficient zero.

**a.aux** This is `NULL` if a feasible solution is found. Otherwise it is the re-expressed auxiliary objective function at the termination of the first phase of the simplex method.

**A** The final constraint matrix which is expressed in terms of the non-basic variables. If a feasible solution is found then this will have dimensions  $m_1+m_2+m_3$  by  $n+m_1+m_2$ , where the final  $m_1+m_2$  columns correspond to slack and surplus variables. If no feasible solution is found there will be an additional  $m_1+m_2+m_3$  columns for the artificial variables introduced to solve the first phase of the problem.

**basic** The indices of the basic (non-zero) variables in the solution. Indices between  $n+1$  and  $n+m_1$  correspond to slack variables, those between  $n+m_1+1$  and  $n+m_2$  correspond to surplus variables and those greater than  $n+m_2$  are artificial variables. Indices greater than  $n+m_2$  should occur only if solved is  $-1$  as the artificial variables are discarded in the second stage of the simplex method.

**slack** The final values of the  $m_1$  slack variables which arise when the " $\leq$ " constraints are re-expressed as the equalities  $A1 \% x + \text{slack} = b1$ .

**surplus** The final values of the  $m_2$  surplus variables which arise when the " $\leq$ " constraints are re-expressed as the equalities  $A2 \% x - \text{surplus} = b2$ .

**artificial** This is NULL if a feasible solution can be found. If no solution can be found then this contains the values of the  $m_1+m_2+m_3$  artificial variables which minimize their sum subject to the original constraints. A feasible solution exists only if all of the artificial variables can be made 0 simultaneously.

smooth.f

*Smooth Distributions on Data Points*

---

### Description

This function uses the method of frequency smoothing to find a distribution on a data set which has a required value, theta, of the statistic of interest. The method results in distributions which vary smoothly with theta.

### Usage

```
smooth.f(theta, boot.out, index = 1, t = boot.out$t[, index],
 width = 0.5)
```

### Arguments

|          |                                                                                                                                                                                                                                                                                                                                                                 |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| theta    | The required value for the statistic of interest. If theta is a vector, a separate distribution will be found for each element of theta.                                                                                                                                                                                                                        |
| boot.out | A bootstrap output object returned by a call to boot.                                                                                                                                                                                                                                                                                                           |
| index    | The index of the variable of interest in the output of boot.out\$statistic. This argument is ignored if t is supplied. index must be a scalar.                                                                                                                                                                                                                  |
| t        | The bootstrap values of the statistic of interest. This must be a vector of length boot.out\$R and the values must be in the same order as the bootstrap replicates in boot.out.                                                                                                                                                                                |
| width    | The standardized width for the kernel smoothing. The smoothing uses a value of width*s for epsilon, where s is the bootstrap estimate of the standard error of the statistic of interest. width should take a value in the range (0.2, 1) to produce a reasonable smoothed distribution. If width is too large then the distribution becomes closer to uniform. |

## Details

The new distributional weights are found by applying a normal kernel smoother to the observed values of  $t$  weighted by the observed frequencies in the bootstrap simulation. The resulting distribution may not have parameter value exactly equal to the required value  $\theta$  but it will typically have a value which is close to  $\theta$ . The details of how this method works can be found in Davison, Hinkley and Worton (1995) and Section 3.9.2 of Davison and Hinkley (1997).

## Value

If `length(theta)` is 1 then a vector with the same length as the data set `boot.out$data` is returned. The value in position  $i$  is the probability to be given to the data point in position  $i$  so that the distribution has parameter value approximately equal to  $\theta$ . If `length(theta)` is bigger than 1 then the returned value is a matrix with `length(theta)` rows each of which corresponds to a distribution with the parameter value approximately equal to the corresponding value of  $\theta$ .

## Examples

```
Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
distribution of the studentized statistic to be centred at the observed
value of the test statistic 1.84. In the book exponential tilting was used
but it is also possible to use smooth.f.
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7,]
grav.fun <- function(dat, w, orig) {
 strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
 d <- dat[, 1]
 ns <- tabulate(strata)
 w <- w/tapply(w, strata, sum)[strata]
 mns <- as.vector(tapply(d * w, strata, sum)) # drop names
 mn2 <- tapply(d * d * w, strata, sum)
 s2hat <- sum((mn2 - mns^2)/ns)
 c(mns[2] - mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
 strata = grav1[, 2], orig = grav.z0[1])
grav.sm <- smooth.f(grav.z0[3], grav.boot, index = 3)

Now we can run another bootstrap using these weights
grav.boot2 <- boot(grav1, grav.fun, R = 499, stype = "w",
 strata = grav1[, 2], orig = grav.z0[1],
 weights = grav.sm)

Estimated p-values can be found from these as follows
mean(grav.boot$t[, 3] >= grav.z0[3])
```

```
imp.prob(grav.boot2, t0 = -grav.z0[3], t = -grav.boot2$t[, 3])

Note that for the importance sampling probability we must
multiply everything by -1 to ensure that we find the correct
probability. Raw resampling is not reliable for probabilities
greater than 0.5. Thus
1 - imp.prob(grav.boot2, index = 3, t0 = grav.z0[3])$raw
can give very strange results (negative probabilities).
```

|---------|------------------------------------|
| sunspot | <i>Annual Mean Sunspot Numbers</i> |
|---------|------------------------------------|

---

### Description

sunspot is a time series and contains 289 observations.

The Zurich sunspot numbers have been analyzed in almost all books on time series analysis as well as numerous papers. The data set, usually attributed to Rudolf Wolf, consists of means of daily relative numbers of sunspot sightings. The relative number for a day is given by  $k(f+10g)$  where  $g$  is the number of sunspot groups observed,  $f$  is the total number of spots within the groups and  $k$  is a scaling factor relating the observer and telescope to a baseline. The relative numbers are then averaged to give an annual figure. See Inzenman (1983) for a discussion of the relative numbers. The figures are for the years 1700-1988.

|----------|-----------------------------------------------|
| survival | <i>Survival of Rats after Radiation Doses</i> |
|----------|-----------------------------------------------|

---

### Description

The survival data frame has 14 rows and 2 columns.

The data measured the survival percentages of batches of rats who were given varying doses of radiation. At each of 6 doses there were two or three replications of the experiment.

### Usage

```
survival
```

**Format**

This data frame contains the following columns:

dose The dose of radiation administered (rads).

surv The survival rate of the batches expressed as a percentage.

**Source**

The data were obtained from

|-----|---------------------------------|
| tau | <i>Tau Particle Decay Modes</i> |
|-----|---------------------------------|

---

**Description**

The tau data frame has 60 rows and 2 columns.

The tau particle is a heavy electron-like particle discovered in the 1970's by Martin Perl at the Stanford Linear Accelerator Center. Soon after its production the tau particle decays into various collections of more stable particles. About 86% of the time the decay involves just one charged particle. This rate has been measured independently 13 times.

The one-charged-particle event is made up of four major modes of decay as well as a collection of other events. The four main types of decay are denoted rho, pi, e and mu. These rates have been measured independently 6, 7, 14 and 19 times respectively. Due to physical constraints each experiment can only estimate the composite one-charged-particle decay rate or the rate of one of the major modes of decay.

Each experiment consists of a major research project involving many years work. One of the goals of the experiments was to estimate the rate of decay due to events other than the four main modes of decay. These are uncertain events and so cannot themselves be observed directly.

**Usage**

tau

**Format**

This data frame contains the following columns:

rate The decay rate expressed as a percentage.

decay The type of decay measured in the experiment. It is a factor with levels 1, rho, pi, e and mu.

**Source**

The data were obtained from

---

tilt.boot

---

Non-parametric Tilted Bootstrap

---

## Description

This function will run an initial bootstrap with equal resampling probabilities (if required) and will use the output of the initial run to find resampling probabilities which put the value of the statistic at required values. It then runs an importance resampling bootstrap using the calculated probabilities as the resampling distribution.

## Usage

```
tilt.boot(data, statistic, R, sim = "ordinary", stype = "i",
 strata = rep(1, n), L = NULL, theta = NULL,
 alpha = c(0.025, 0.975), tilt = TRUE, width = 0.5,
 index = 1, ...)
```

## Arguments

- |           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data      | The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one (multivariate) observation.                                                                                                                                                                                                                                                                                                                                           |
| statistic | A function which when applied to data returns a vector containing the statistic(s) of interest. It must take at least two arguments. The first argument will always be data and the second should be a vector of indices, weights or frequencies describing the bootstrap sample. Any other arguments must be supplied to tilt.boot and will be passed unchanged to statistic each time it is called.                                                                                |
| R         | The number of bootstrap replicates required. This will generally be a vector, the first value stating how many uniform bootstrap simulations are to be performed at the initial stage. The remaining values of R are the number of simulations to be performed resampling from each reweighted distribution. The first value of R must always be present, a value of 0 implying that no uniform resampling is to be carried out. Thus length(R) should always equal 1+length(theta). |
| sim       | This is a character string indicating the type of bootstrap simulation required. There are only two possible values that this can take: "ordinary" and "balanced". If other simulation types are required for the initial un-weighted bootstrap then it will be necessary to run boot, calculate the weights appropriately, and run boot again using the calculated weights.                                                                                                         |
| stype     | A character string indicating the type of second argument expected by statistic. The possible values that stype can take are "i" (indices), "w" (weights) and "f" (frequencies).                                                                                                                                                                                                                                                                                                     |
| strata    | An integer vector or factor representing the strata for multi-sample problems.                                                                                                                                                                                                                                                                                                                                                                                                       |

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| L     | The empirical influence values for the statistic of interest. They are used only for exponential tilting when <code>tilt</code> is TRUE. If <code>tilt</code> is TRUE and they are not supplied then <code>tilt.boot</code> uses <code>empinf</code> to calculate them.                                                                                                                                                                                                                                               |
| theta | The required parameter value(s) for the tilted distribution(s). There should be one value of <code>theta</code> for each of the non-uniform distributions. If <code>R[1]</code> is 0 <code>theta</code> is a required argument. Otherwise <code>theta</code> values can be estimated from the initial uniform bootstrap and the values in <code>alpha</code> .                                                                                                                                                        |
| alpha | The alpha level to which tilting is required. This parameter is ignored if <code>R[1]</code> is 0 or if <code>theta</code> is supplied, otherwise it is used to find the values of <code>theta</code> as quantiles of the initial uniform bootstrap. In this case <code>R[1]</code> should be large enough that $\min(c(\alpha, 1-\alpha)) * R[1] > 5$ , if this is not the case then a warning is generated to the effect that the <code>theta</code> are extreme values and so the tilted output may be unreliable. |
| tilt  | A logical variable which if TRUE (the default) indicates that exponential tilting should be used, otherwise local frequency smoothing ( <code>smooth.f</code> ) is used. If <code>tilt</code> is FALSE then <code>R[1]</code> must be positive. In fact in this case the value of <code>R[1]</code> should be fairly large (in the region of 500 or more).                                                                                                                                                            |
| width | This argument is used only if <code>tilt</code> is FALSE, in which case it is passed unchanged to <code>smooth.f</code> as the standardized bandwidth for the smoothing operation. The value should generally be in the range (0.2, 1). See <code>smooth.f</code> for more details.                                                                                                                                                                                                                                   |
| index | The index of the statistic of interest in the output from <code>statistic</code> . By default the first element of the output of <code>statistic</code> is used.                                                                                                                                                                                                                                                                                                                                                      |
| ...   | Any additional arguments required by <code>statistic</code> . These are passed unchanged to <code>statistic</code> each time it is called.                                                                                                                                                                                                                                                                                                                                                                            |

## Value

An object of class "boot" with the following components

|           |                                                                                                                                                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| t0        | The observed value of the statistic on the original data.                                                                                                                                                                                                                |
| t         | The values of the bootstrap replicates of the statistic. There will be <code>sum(R)</code> of these, the first <code>R[1]</code> corresponding to the uniform bootstrap and the remainder to the tilted bootstrap(s).                                                    |
| R         | The input vector of the number of bootstrap replicates.                                                                                                                                                                                                                  |
| data      | The original data as supplied.                                                                                                                                                                                                                                           |
| statistic | The <code>statistic</code> function as supplied.                                                                                                                                                                                                                         |
| sim       | The simulation type used in the bootstrap(s), it can either be "ordinary" or "balanced".                                                                                                                                                                                 |
| stype     | The type of statistic supplied, it is the same as the input value <code>stype</code> .                                                                                                                                                                                   |
| call      | A copy of the original call to <code>tilt.boot</code> .                                                                                                                                                                                                                  |
| strata    | The strata as supplied.                                                                                                                                                                                                                                                  |
| weights   | The matrix of weights used. If <code>R[1]</code> is greater than 0 then the first row will be the uniform weights and each subsequent row the tilted weights. If <code>R[1]</code> equals 0 then the uniform weights are omitted and only the tilted weights are output. |
| theta     | The values of <code>theta</code> used for the tilted distributions. These are either the input values or the values derived from the uniform bootstrap and <code>alpha</code> .                                                                                          |

## Examples

```
Note that these examples can take a while to run.

Example 9.9 of Davison and Hinkley (1997).
grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
grav.fun <- function(dat, w, orig) {
 strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
 d <- dat[, 1]
 ns <- tabulate(strata)
 w <- w/tapply(w, strata, sum)[strata]
 mns <- as.vector(tapply(d * w, strata, sum)) # drop names
 mn2 <- tapply(d * d * w, strata, sum)
 s2hat <- sum((mn2 - mns^2)/ns)
 c(mns[2]-mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
tilt.boot(grav1, grav.fun, R = c(249, 375, 375), stype = "w",
 strata = grav1[,2], tilt = TRUE, index = 3, orig = grav.z0[1])

Example 9.10 of Davison and Hinkley (1997) requires a balanced
importance resampling bootstrap to be run. In this example we
show how this might be run.
acme.fun <- function(data, i, bhat) {
 d <- data[i,]
 n <- nrow(d)
 d.lm <- glm(d$acme~d$market)
 beta.b <- coef(d.lm)[2]
 d.diag <- boot::glm.diag(d.lm)
 SSx <- (n-1)*var(d$market)
 tmp <- (d$market-mean(d$market))*d.diag$res*d.diag$sd
 sr <- sqrt(sum(tmp^2))/SSx
 c(beta.b, sr, (beta.b-bhat)/sr)
}
acme.b <- acme.fun(acme, 1:nrow(acme), 0)
acme.boot1 <- tilt.boot(acme, acme.fun, R = c(499, 250, 250),
 stype = "i", sim = "balanced", alpha = c(0.05, 0.95),
 tilt = TRUE, index = 3, bhat = acme.b[1])
```

**Description**

Generate R bootstrap replicates of a statistic applied to a time series. The replicate time series can be generated using fixed or random block lengths or can be model based replicates.

**Usage**

```
tsboot(tseries, statistic, R, l = NULL, sim = "model",
 endcorr = TRUE, n.sim = NROW(tseries), orig.t = TRUE,
 ran.gen, ran.args = NULL, norm = TRUE, ...,
 parallel = c("no", "multicore", "snow"),
 ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tseries   | A univariate or multivariate time series.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| statistic | A function which when applied to tseries returns a vector containing the statistic(s) of interest. Each time statistic is called it is passed a time series of length n.sim which is of the same class as the original tseries. Any other arguments which statistic takes must remain constant for each bootstrap replicate and should be supplied through the ...argument to tsboot.                                                                              |
| R         | A positive integer giving the number of bootstrap replicates required.                                                                                                                                                                                                                                                                                                                                                                                             |
| sim       | The type of simulation required to generate the replicate time series. The possible input values are "model" (model based resampling), "fixed" (block resampling with fixed block lengths of 1), "geom" (block resampling with block lengths having a geometric distribution with mean 1) or "scramble" (phase scrambling).                                                                                                                                        |
| l         | If sim is "fixed" then l is the fixed block length used in generating the replicate time series. If sim is "geom" then l is the mean of the geometric distribution used to generate the block lengths. l should be a positive integer less than the length of tseries. This argument is not required when sim is "model" but it is required for all other simulation types.                                                                                        |
| endcorr   | A logical variable indicating whether end corrections are to be applied when sim is "fixed". When sim is "geom", endcorr is automatically set to TRUE; endcorr is not used when sim is "model" or "scramble".                                                                                                                                                                                                                                                      |
| n.sim     | The length of the simulated time series. Typically this will be equal to the length of the original time series but there are situations when it will be larger. One obvious situation is if prediction is required. Another situation in which n.sim is larger than the original length is if tseries is a residual time series from fitting some model to the original time series. In this case, n.sim would usually be the length of the original time series. |
| orig.t    | A logical variable which indicates whether statistic should be applied to tseries itself as well as the bootstrap replicate series. If statistic is expecting a longer time series than tseries or if applying statistic to tseries will not yield any useful information then orig.t should be set to FALSE.                                                                                                                                                      |

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ran.gen</code>             | This is a function of three arguments. The first argument is a time series. If <code>sim</code> is "model" then it will always be <code>tseries</code> that is passed. For other simulation types it is the result of selecting <code>n.sim</code> observations from <code>tseries</code> by some scheme and converting the result back into a time series of the same form as <code>tseries</code> (although of length <code>n.sim</code> ). The second argument to <code>ran.gen</code> is always the value <code>n.sim</code> , and the third argument is <code>ran.args</code> , which is used to supply any other objects needed by <code>ran.gen</code> . If <code>sim</code> is "model" then the generation of the replicate time series will be done in <code>ran.gen</code> (for example through use of <a href="#">arima.sim</a> ). For the other simulation types <code>ran.gen</code> is used for 'post-blackening'. The default is that the function simply returns the time series passed to it. |
| <code>ran.args</code>            | This will be supplied to <code>ran.gen</code> each time it is called. If <code>ran.gen</code> needs any extra arguments then they should be supplied as components of <code>ran.args</code> . Multiple arguments may be passed by making <code>ran.args</code> a list. If <code>ran.args</code> is <code>NULL</code> then it should not be used within <code>ran.gen</code> but note that <code>ran.gen</code> must still have its third argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>norm</code>                | A logical argument indicating whether normal margins should be used for phase scrambling. If <code>norm</code> is <code>FALSE</code> then margins corresponding to the exact empirical margins are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>...</code>                 | Extra named arguments to <code>statistic</code> may be supplied here. Beware of partial matching to the arguments of <code>tsboot</code> listed above.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>parallel, ncpus, cl</code> | See the help for <a href="#">boot</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

If `sim` is "fixed" then each replicate time series is found by taking blocks of length 1, from the original time series and putting them end-to-end until a new series of length `n.sim` is created. When `sim` is "geom" a similar approach is taken except that now the block lengths are generated from a geometric distribution with mean 1. Post-blackening can be carried out on these replicate time series by including the function `ran.gen` in the call to `tsboot` and having `tseries` as a time series of residuals.

Model based resampling is very similar to the parametric bootstrap and all simulation must be in one of the user specified functions. This avoids the complicated problem of choosing the block length but relies on an accurate model choice being made.

Phase scrambling is described in Section 8.2.4 of Davison and Hinkley (1997). The types of statistic for which this method produces reasonable results is very limited and the other methods seem to do better in most situations. Other types of resampling in the frequency domain can be accomplished using the function `boot` with the argument `sim = "parametric"`.

## Value

An object of class "boot" with the following components.

|                        |                                                                                                                                                             |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t0</code>        | If <code>orig.t</code> is <code>TRUE</code> then <code>t0</code> is the result of <code>statistic(tseries,...{})</code> otherwise it is <code>NULL</code> . |
| <code>t</code>         | The results of applying <code>statistic</code> to the replicate time series.                                                                                |
| <code>R</code>         | The value of <code>R</code> as supplied to <code>tsboot</code> .                                                                                            |
| <code>tseries</code>   | The original time series.                                                                                                                                   |
| <code>statistic</code> | The function <code>statistic</code> as supplied.                                                                                                            |

|          |                                                                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sim      | The simulation type used in generating the replicates.                                                                                                                                |
| endcorr  | The value of endcorr used. The value is meaningful only when sim is "fixed"; it is ignored for model based simulation or phase scrambling and is always set to TRUE if sim is "geom". |
| n.sim    | The value of n.sim used.                                                                                                                                                              |
| l        | The value of l used for block based resampling. This will be NULL if block based resampling was not used.                                                                             |
| ran.gen  | The ran.gen function used for generating the series or for 'post-blackening'.                                                                                                         |
| ran.args | The extra arguments passed to ran.gen.                                                                                                                                                |
| call     | The original call to tsboot.                                                                                                                                                          |

## See Also

[boot](#), [arima.sim](#)

## Examples

```
lynx.fun <- function(tsb) {
 ar.fit <- ar(tsb, order.max = 25)
 c(ar.fit$order, mean(tsb), tsb)
}

the stationary bootstrap with mean block length 20
lynx.1 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "geom")

the fixed block bootstrap with length 20
lynx.2 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "fixed")

Now for model based resampling we need the original model
Note that for all of the bootstraps which use the residuals as their
data, we set orig.t to FALSE since the function applied to the residual
time series will be meaningless.
lynx.ar <- ar(log(lynx))
lynx.model <- list(order = c(lynx.ar$order, 0, 0), ar = lynx.ar$ar)
lynx.res <- lynx.ar$resid[!is.na(lynx.ar$resid)]
lynx.res <- lynx.res - mean(lynx.res)

lynx.sim <- function(res,n.sim, ran.args) {
 # random generation of replicate series using arima.sim
 rg1 <- function(n, res) sample(res, n, replace = TRUE)
 ts.orig <- ran.args$ts
 ts.mod <- ran.args$model
 mean(ts.orig)+ts(arima.sim(model = ts.mod, n = n.sim,
 rand.gen = rg1, res = as.vector(res)))
}
```

```

}

lynx.3 <- tsboot(lynx.res, lynx.fun, R = 99, sim = "model", n.sim = 114,
 orig.t = FALSE, ran.gen = lynx.sim,
 ran.args = list(ts = log(lynx), model = lynx.model))

For "post-blackening" we need to define another function
lynx.black <- function(res, n.sim, ran.args) {
 ts.orig <- ran.args$ts
 ts.mod <- ran.args$model
 mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim, innov = res))
}

Now we can run apply the two types of block resampling again but this
time applying post-blackening.
lynx.1b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "fixed",
 n.sim = 114, orig.t = FALSE, ran.gen = lynx.black,
 ran.args = list(ts = log(lynx), model = lynx.model))

lynx.2b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "geom",
 n.sim = 114, orig.t = FALSE, ran.gen = lynx.black,
 ran.args = list(ts = log(lynx), model = lynx.model))

To compare the observed order of the bootstrap replicates we
proceed as follows.
table(lynx.1$t[, 1])
table(lynx.1b$t[, 1])
table(lynx.2$t[, 1])
table(lynx.2b$t[, 1])
table(lynx.3$t[, 1])
Notice that the post-blackened and model-based bootstraps preserve
the true order of the model (11) in many more cases than the others.

tuna

---

*Tuna Sighting Data*

---

## Description

The tuna data frame has 64 rows and 1 columns.

The data come from an aerial line transect survey of Southern Bluefin Tuna in the Great Australian Bight. An aircraft with two spotters on board flies randomly allocated line transects. Each school of tuna sighted is counted and its perpendicular distance from the transect measured. The survey was conducted in summer when tuna tend to stay on the surface.

## Usage

```
tuna
```

## Format

This data frame contains the following column:

- y The perpendicular distance, in miles, from the transect for 64 independent sightings of tuna schools.

**Source**

The data were obtained from

Chen, S.X. (1996) Empirical likelihood confidence intervals for nonparametric density estimation. *Biometrika*, **83**, 329–341.

---

urine

*Urine Analysis Data*

---

**Description**

The urine data frame has 79 rows and 7 columns.

79 urine specimens were analyzed in an effort to determine if certain physical characteristics of the urine might be related to the formation of calcium oxalate crystals.

**Usage**

urine

**Format**

This data frame contains the following columns:

r Indicator of the presence of calcium oxalate crystals.

gravity The specific gravity of the urine.

ph The pH reading of the urine.

osmo The osmolarity of the urine. Osmolarity is proportional to the concentration of molecules in solution.

cond The conductivity of the urine. Conductivity is proportional to the concentration of charged ions in solution.

urea The urea concentration in millimoles per litre.

calc The calcium concentration in millimoles per litre.

|------------|---------------------------------|
| var.linear | <i>Linear Variance Estimate</i> |
|------------|---------------------------------|

---

**Description**

Estimates the variance of a statistic from its empirical influence values.

**Usage**

```
var.linear(L, strata = NULL)
```

**Arguments**

|        |                                                                                                                              |
|--------|------------------------------------------------------------------------------------------------------------------------------|
| L      | Vector of the empirical influence values of a statistic. These will usually be calculated by a call to <code>empinf</code> . |
| strata | A numeric vector or factor specifying which observations (and hence empirical influence values) come from which strata.      |

**Value**

The variance estimate calculated from L.

|------|----------------------------------------|
| wool | <i>Australian Relative Wool Prices</i> |
|------|----------------------------------------|

---

**Description**

wool is a time series of class "ts" and contains 309 observations.

Each week that the market is open the Australian Wool Corporation set a floor price which determines their policy on intervention and is therefore a reflection of the overall price of wool for the week in question. Actual prices paid can vary considerably about the floor price. The series here is the log of the ratio between the price for fine grade wool and the floor price, each market week between July 1976 and Jun 1984.

## Chapter 19

# The class package

---

batchSOM

*Self-Organizing Maps: Batch Algorithm*

---

### Description

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

### Usage

```
batchSOM(data, grid = somgrid(), radii, init)
```

### Arguments

|       |                                                                                                     |
|-------|-----------------------------------------------------------------------------------------------------|
| data  | a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.           |
| grid  | A grid for the representatives: see <a href="#">somgrid</a> .                                       |
| radii | the radii of the neighbourhood to be used for each pass: one pass is run for each element of radii. |
| init  | the initial representatives. If missing, chosen (without replacement) randomly from data.           |

### Details

The batch SOM algorithm of Kohonen(1995, section 3.14) is used.

### Value

An object of class "SOM" with components

|       |                                         |
|-------|-----------------------------------------|
| grid  | the grid, an object of class "somgrid". |
| codes | a matrix of representatives.            |

|----------|--------------------------------------------------|
| condense | <i>Condense training set for k-NN classifier</i> |
|----------|--------------------------------------------------|

---

Description

Condense training set for k-NN classifier

Usage

```
condense(train, class, store, trace = TRUE)
```

Arguments

|       |                                                                    |
|-------|--------------------------------------------------------------------|
| train | matrix for training set                                            |
| class | vector of classifications for test set                             |
| store | initial store set. Default one randomly chosen element of the set. |
| trace | logical. Trace iterations?                                         |

Details

The store set is used to 1-NN classify the rest, and misclassified patterns are added to the store set. The whole set is checked until no additions occur.

Value

Index vector of cases to be retained (the final store set).

|-----|-------------------------------------------|
| knn | <i>k-Nearest Neighbour Classification</i> |
|-----|-------------------------------------------|

---

## Description

k-nearest neighbour classification for test set from training set. For each row of the test set, the k nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.

## Usage

```
knn(train, test, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

## Arguments

|         |                                                                                                                                                                                            |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| train   | matrix or data frame of training set cases.                                                                                                                                                |
| test    | matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.                                                                                    |
| cl      | factor of true classifications of training set                                                                                                                                             |
| k       | number of neighbours considered.                                                                                                                                                           |
| l       | minimum vote for definite decision, otherwise doubt. (More precisely, less than k-1 dissenting votes are allowed, even if k is increased by ties.)                                         |
| prob    | If this is true, the proportion of the votes for the winning class are returned as attribute prob.                                                                                         |
| use.all | controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours. |

**Value**

Factor of classifications of test set. doubt will be returned as NA.

*k-Nearest Neighbour Cross-Validatory Classification*

---

**Description**

k-nearest neighbour cross-validatory classification from training set.

**Usage**

```
knn.cv(train, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

**Arguments**

|         |                                                                                                                                                                                            |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| train   | matrix or data frame of training set cases.                                                                                                                                                |
| cl      | factor of true classifications of training set                                                                                                                                             |
| k       | number of neighbours considered.                                                                                                                                                           |
| l       | minimum vote for definite decision, otherwise doubt. (More precisely, less than k-1 dissenting votes are allowed, even if k is increased by ties.)                                         |
| prob    | If this is true, the proportion of the votes for the winning class are returned as attribute prob.                                                                                         |
| use.all | controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours. |

**Details**

This uses leave-one-out cross validation. For each row of the training set train, the k nearest (in Euclidean distance) other training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.

**Value**

Factor of classifications of training set. doubt will be returned as NA.

attributes(.Last.value)
```

---

knn1

---

*1-Nearest Neighbour Classification*

---

**Description**

Nearest neighbour classification for test set from training set. For each row of the test set, the nearest (by Euclidean distance) training set vector is found, and its classification used. If there is more than one nearest, a majority vote is used with ties broken at random.

**Usage**

```
knn1(train, test, cl)
```

**Arguments**

|       |                                                                                                         |
|-------|---------------------------------------------------------------------------------------------------------|
| train | matrix or data frame of training set cases.                                                             |
| test  | matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case. |
| cl    | factor of true classification of training set.                                                          |

**Value**

Factor of classifications of test set.

```

lvq1

*Learning Vector Quantization I***Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
lvq1(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03)
```

**Arguments**

|        |                                                        |
|--------|--------------------------------------------------------|
| x      | a matrix or data frame of examples                     |
| cl     | a vector or factor of classifications for the examples |
| codebk | a codebook                                             |
| niter  | number of iterations                                   |
| alpha  | constant for training                                  |

**Details**

Selects niter examples at random with replacement, and adjusts the nearest example in the codebook for each.

**Value**

A codebook, represented as a list with components x and cl giving the examples and classes.

*Learning Vector Quantization 2.1***Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
lvq2(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03,
 win = 0.3)
```

**Arguments**

|        |                                                           |
|--------|-----------------------------------------------------------|
| x      | a matrix or data frame of examples                        |
| cl     | a vector or factor of classifications for the examples    |
| codebk | a codebook                                                |
| niter  | number of iterations                                      |
| alpha  | constant for training                                     |
| win    | a tolerance for the closeness of the two nearest vectors. |

**Details**

Selects niter examples at random with replacement, and adjusts the nearest two examples in the codebook if one is correct and the other incorrect.

**Value**

A codebook, represented as a list with components x and cl giving the examples and classes.

|------|---------------------------------------|
| lvq3 | <i>Learning Vector Quantization 3</i> |
|------|---------------------------------------|

---

**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
lvq3(x, cl, codebk, niter = 100*nrow(codebk$x), alpha = 0.03,
 win = 0.3, epsilon = 0.1)
```

**Arguments**

- x                    a matrix or data frame of examples
- cl                   a vector or factor of classifications for the examples
- codebk               a codebook
- niter                number of iterations
- alpha                constant for training
- win                   a tolerance for the closeness of the two nearest vectors.
- epsilon              proportion of move for correct vectors

**Details**

Selects niter examples at random with replacement, and adjusts the nearest two examples in the codebook for each.

**Value**

A codebook, represented as a list with components x and cl giving the examples and classes.

|---------|----------------------------------|

---

## Description

Construct an initial codebook for LVQ methods.

## Usage

```
lvqinit(x, cl, size, prior, k = 5)
```

## Arguments

- |       |                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x     | a matrix or data frame of training examples, n by p.                                                                                                          |
| cl    | the classifications for the training examples. A vector or factor of length n.                                                                                |
| size  | the size of the codebook. Defaults to $\min(\text{round}(0.4 \cdot \text{ng} \cdot (\text{ng} - 1 + p/2)), 0), \text{ng})$ where ng is the number of classes. |
| prior | Probabilities to represent classes in the codebook. Default proportions in the training set.                                                                  |
| k     | k used for k-NN test of correct classification. Default is 5.                                                                                                 |

## Details

Selects size examples from the training set without replacement with proportions proportional to the prior or the original proportions.

## Value

A codebook, represented as a list with components x and cl giving the examples and classes.

| lvqtest | <i>Classify Test Set from LVQ Codebook</i> |
|---------|--------------------------------------------|

---

Description

Classify a test set by 1-NN from a specified LVQ codebook.

Usage

```
lvqtest(codebk, test)
```

Arguments

|        |                                                |
|--------|------------------------------------------------|
| codebk | codebook object returned by other LVQ software |
| test   | matrix of test examples                        |

Details

Uses 1-NN to classify each test example against the codebook.

Value

Factor of classification for each row of x

function(codebk, test) knn1(codebk$x, test, codebk$c1)
```

---

`multiedit`*Multiedit for k-NN Classifier*

---

**Description**

Multiedit for k-NN classifier

**Usage**

```
multiedit(x, class, k = 1, V = 3, I = 5, trace = TRUE)
```

**Arguments**

|                    |                                           |
|--------------------|-------------------------------------------|
| <code>x</code>     | matrix of training set.                   |
| <code>class</code> | vector of classification of training set. |
| <code>k</code>     | number of neighbours used in k-NN.        |
| <code>V</code>     | divide training set into V parts.         |
| <code>I</code>     | number of null passes before quitting.    |
| <code>trace</code> | logical for statistics at each pass.      |

**Value**

Index vector of cases to be retained.

**Examples**

```
tr <- sample(1:50, 25)
train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep(1,25),rep(2,25), rep(3,25)), labels=c("s", "c", "v"))
table(cl, knn(train, test, cl, 3))
ind1 <- multiedit(train, cl, 3)
length(ind1)
table(cl, knn(train[ind1, , drop=FALSE], test, cl[ind1], 1))
ntrain <- train[ind1,]; ncl <- cl[ind1]
ind2 <- condense(ntrain, ncl)
length(ind2)
table(cl, knn(ntrain[ind2, , drop=FALSE], test, ncl[ind2], 1))
```

olvq1

*Optimized Learning Vector Quantization 1***Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
olvq1(x, cl, codebk, niter = 40 * nrow(codebk$x), alpha = 0.3)
```

**Arguments**

|        |                                                        |
|--------|--------------------------------------------------------|
| x      | a matrix or data frame of examples                     |
| cl     | a vector or factor of classifications for the examples |
| codebk | a codebook                                             |
| niter  | number of iterations                                   |
| alpha  | constant for training                                  |

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

lvqtest(cd1, train)
```

---

reduce.nn

*Reduce Training Set for a k-NN Classifier*

---

**Description**

Reduce training set for a k-NN classifier. Used after condense.

**Usage**

```
reduce.nn(train, ind, class)
```

**Arguments**

|       |                                                              |
|-------|--------------------------------------------------------------|
| train | matrix for training set                                      |
| ind   | Initial list of members of the training set (from condense). |
| class | vector of classifications for test set                       |

**Details**

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

**Value**

Index vector of cases to be retained.

cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
keep <- condense(train, cl)
knn(train[keep,], test, cl[keep])
keep2 <- reduce.nn(train, keep, cl)
knn(train[keep2,], test, cl[keep2])

```

SOM

*Self-Organizing Maps: Online Algorithm***Description**

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

**Usage**

```
SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)
```

**Arguments**

|                    |                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>  | a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.                                                                                             |
| <code>grid</code>  | A grid for the representatives: see <a href="#">somgrid</a> .                                                                                                                         |
| <code>rlen</code>  | the number of updates: used only in the defaults for <code>alpha</code> and <code>radii</code> .                                                                                      |
| <code>alpha</code> | the amount of change: one update is done for each element of <code>alpha</code> . Default is to decline linearly from 0.05 to 0 over <code>rlen</code> updates.                       |
| <code>radii</code> | the radii of the neighbourhood to be used for each update: must be the same length as <code>alpha</code> . Default is to decline linearly from 4 to 1 over <code>rlen</code> updates. |
| <code>init</code>  | the initial representatives. If missing, chosen (without replacement) randomly from data.                                                                                             |

**Details**

`alpha` and `radii` can also be lists, in which case each component is used in turn, allowing two- or more phase training.

**Value**

An object of class "SOM" with components

|                    |                                         |
|--------------------|-----------------------------------------|
| <code>grid</code>  | the grid, an object of class "somgrid". |
| <code>codes</code> | a matrix of representatives.            |

## Examples

```
require(graphics)
data(crabs, package = "MASS")

lcrabs <- log(crabs[, 4:8])
crabs.grp <- factor(c("B", "b", "O", "o")[rep(1:4, rep(50,4))])
gr <- somgrid(topo = "hexagonal")
crabs.som <- SOM(lcrabs, gr)
plot(crabs.som)

2-phase training
crabs.som2 <- SOM(lcrabs, gr,
 alpha = list(seq(0.05, 0, length.out = 1e4), seq(0.02, 0, length.out = 1e5)),
 radii = list(seq(8, 1, length.out = 1e4), seq(4, 1, length.out = 1e5)))
plot(crabs.som2)
```

---

somgrid

*Plot SOM Fits*

---

## Description

Plotting functions for SOM results.

## Usage

```
somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))

S3 method for class 'somgrid'
plot(x, type = "p", ...)

S3 method for class 'SOM'
plot(x, ...)
```

## Arguments

|            |                                                     |
|------------|-----------------------------------------------------|
| xdim, ydim | dimensions of the grid                              |
| topo       | the topology of the grid.                           |
| x          | an object inheriting from class "somgrid" or "SOM". |
| type, ...  | graphical parameters.                               |

**Details**

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.

The plot method for class "SOM" plots a [stars](#) plot of the representative at each grid point.

**Value**

For somgrid, an object of class "somgrid", a list with components

pts                    a two-column matrix giving locations for the grid points.

xdim, ydim, topo    as in the arguments to somgrid.

## Chapter 20

# The cluster package

---

agnes

*Agglomerative Nesting (Hierarchical Clustering)*

---

### Description

Computes agglomerative hierarchical clustering of the dataset.

### Usage

```
agnes(x, diss = inherits(x, "dist"), metric = "euclidean",
 stand = FALSE, method = "average", par.method,
 keep.diss = n < 100, keep.data = !diss, trace.lev = 0)
```

### Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | <p>data matrix or data frame, or dissimilarity matrix, depending on the value of the diss argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, x is typically the output of <a href="#">daisy</a> or <a href="#">dist</a>. Also a vector with length <math>n*(n-1)/2</math> is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p> |
| diss   | <p>logical flag: if TRUE (default for dist or dissimilarity objects), then x is assumed to be a dissimilarity matrix. If FALSE, then x is treated as a matrix of observations by variables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| metric | <p>character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If x is already a dissimilarity matrix, then this argument will be ignored.</p>                                                                                                                                                                                                                                                                           |
| stand  | <p>logical flag: if TRUE, then the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>method</code>               | character string defining the clustering method. The six methods implemented are "average" ([unweighted pair-]group [arithMetic] average method, aka 'UPGMA'), "single" (single linkage), "complete" (complete linkage), "ward" (Ward's method), "weighted" (weighted average linkage, aka 'WPGMA'), its generalization "flexible" which uses (a constant version of) the Lance-Williams formula and the <code>par.method</code> argument, and "gaverage" a generalized "average" aka "flexible UPGMA" method also using the Lance-Williams formula and <code>par.method</code> .<br>The default is "average". |
| <code>par.method</code>           | If <code>method</code> is "flexible" or "gaverage", a numeric vector of length 1, 3, or 4, (with a default for "gaverage"), see in the details section.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Details

`agnes` is fully described in chapter 5 of Kaufman and Rousseeuw (1990). Compared to other agglomerative clustering methods such as `hclust`, `agnes` has the following features: (a) it yields the agglomerative coefficient (see [agnes.object](#)) which measures the amount of clustering structure found; and (b) apart from the usual tree it also provides the banner, a novel graphical display (see [plot.agnes](#)).

The `agnes`-algorithm constructs a hierarchy of clusterings.

At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two *nearest* clusters are combined to form one larger cluster.

For `method="average"`, the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In `method="single"`, we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When `method="complete"`, we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The `method = "flexible"` allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K&R(1990), p.237). If clusters  $C_1$  and  $C_2$  are agglomerated into a new cluster, the dissimilarity between their union and another cluster  $Q$  is given by

$$D(C_1 \cup C_2, Q) = \alpha_1 * D(C_1, Q) + \alpha_2 * D(C_2, Q) + \beta * D(C_1, C_2) + \gamma * |D(C_1, Q) - D(C_2, Q)|,$$

where the four coefficients  $(\alpha_1, \alpha_2, \beta, \gamma)$  are specified by the vector `par.method`, either directly as vector of length 4, or (more conveniently) if `par.method` is of length 1, say  $= \alpha$ , `par.method` is extended to give the "Flexible Strategy" (K&R(1990), p.236 f) with Lance-Williams coefficients  $(\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)$ .

Also, if `length(par.method) == 3`,  $\gamma = 0$  is set.

**Care** and expertise is probably needed when using `method = "flexible"` particularly for the case when `par.method` is specified of longer length than one. Since **cluster** version 2.0, choices leading to invalid merge structures now signal an error (from the C code already). The *weighted average* (`method="weighted"`) is the same as `method="flexible", par.method = 0.5`. Further, `method="single"` is equivalent to `method="flexible", par.method = c(.5, .5, 0, -.5)`, and `method="complete"` is equivalent to `method="flexible", par.method = c(.5, .5, 0, +.5)`.

The `method = "gaverage"` is a generalization of "average", aka "flexible UPGMA" method, and is (a generalization of the approach) detailed in Belbin et al. (1992). As "flexible", it uses the Lance-Williams formula above for dissimilarity updating, but with  $\alpha_1$  and  $\alpha_2$  not constant, but *proportional* to the *sizes*  $n_1$  and  $n_2$  of the clusters  $C_1$  and  $C_2$  respectively, i.e.,

$$\alpha_j = \alpha'_j \frac{n_1}{n_1 + n_2},$$

where  $\alpha'_1, \alpha'_2$  are determined from `par.method`, either directly as  $(\alpha_1, \alpha_2, \beta, \gamma)$  or  $(\alpha_1, \alpha_2, \beta)$  with  $\gamma = 0$ , or (less flexibly, but more conveniently) as follows:

Belbin et al proposed "flexible beta", i.e. the user would only specify  $\beta$  (as `par.method`), sensibly in

$$-1 \leq \beta < 1,$$

and  $\beta$  determines  $\alpha'_1$  and  $\alpha'_2$  as

$$\alpha'_j = 1 - \beta,$$

and  $\gamma = 0$ .

This  $\beta$  may be specified by `par.method` (as length 1 vector), and if `par.method` is not specified, a default value of -0.1 is used, as Belbin et al recommend taking a  $\beta$  value around -0.1 as a general agglomerative hierarchical clustering strategy.

Note that `method = "gaverage", par.method = 0` (or `par.method = c(1, 1, 0, 0)`) is equivalent to the `agnes()` default method "average".

## Value

an object of class "agnes" (which extends "twins") representing the clustering. See [agnes.object](#) for details, and methods applicable.

## BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

**Hierarchical methods** like `agnes`, [diana](#), and [mona](#) construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

**Partitioning methods** like [pam](#), [clara](#), and [fanny](#) require that the number of clusters be given by the user.

## Author(s)

Method "gaverage" has been contributed by Pierre Roudier, Landcare Research, New Zealand.

### Examples

```
data(votes.repub)
agn1 <- agnes(votes.repub, metric = "manhattan", stand = TRUE)
agn1
plot(agn1)

op <- par(mfrow=c(2,2))
agn2 <- agnes(daisy(votes.repub), diss = TRUE, method = "complete")
plot(agn2)
alpha = 0.625 ==> beta = -1/4 is "recommended" by some
agnS <- agnes(votes.repub, method = "flexible", par.method = 0.625)
plot(agnS)
par(op)

"show" equivalence of three "flexible" special cases
d.vr <- daisy(votes.repub)
a.wgt <- agnes(d.vr, method = "weighted")
a.sing <- agnes(d.vr, method = "single")
a.comp <- agnes(d.vr, method = "complete")
iC <- -(6:7) # not using 'call' and 'method' for comparisons
stopifnot(
 all.equal(a.wgt[iC], agnes(d.vr, method="flexible", par.method = 0.5)[iC]) ,
 all.equal(a.sing[iC], agnes(d.vr, method="flex", par.method= c(.5,.5,0, -.5))[iC]),
 all.equal(a.comp[iC], agnes(d.vr, method="flex", par.method= c(.5,.5,0, +.5))[iC]))

Exploring the dendrogram structure
(d2 <- as.dendrogram(agn2)) # two main branches
d2[[1]] # the first branch
d2[[2]] # the 2nd one { 8 + 42 = 50 }
d2[[1]][[1]]# first sub-branch of branch 1 .. and shorter form
identical(d2[[c(1,1)]],
 d2[[1]][[1]])
a "textual picture" of the dendrogram :
str(d2)

data(agriculture)

Plot similar to Figure 7 in ref
Not run: plot(agnes(agriculture), ask = TRUE)

data(animals)
aa.a <- agnes(animals) # default method = "average"
aa.ga <- agnes(animals, method = "gaverage")
```

```

op <- par(mfcol=1:2, mgp=c(1.5, 0.6, 0), mar=c(.1+ c(4,3,2,1)),
 cex.main=0.8)
plot(aa.a, which.plots = 2)
plot(aa.ga, which.plots = 2)
par(op)

Show how "gaverage" is a "generalized average":
aa.ga.0 <- agnes(animals, method = "gaverage", par.method = 0)
stopifnot(all.equal(aa.ga.0[iC], aa.a[iC]))

```

---

agnes.object

---

*Agglomerative Nesting (AGNES) Object*

---

## Description

The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.

## Value

A legitimate agnes object is a list with the following components:

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| order     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.                                                                                                                                                                                                                                                                                                                                                                                   |
| order.lab | a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.                                                                                                                                                                                                                                                                                                                                                               |
| height    | a vector with the distances between merging clusters at the successive stages.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ac        | the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $m(i)$ its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The ac is the average of all $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot. Because ac grows with the number of observations, this measure should not be used to compare datasets of very different sizes. |
| merge     | an $(n-1)$ by 2 matrix, where $n$ is the number of observations. Row $i$ of merge describes the merging of clusters at step $i$ of the clustering. If a number $j$ in the row is negative, then the single observation $ j $ is merged at this stage. If $j$ is positive, then the merger is with the cluster formed at stage $j$ of the algorithm.                                                                                                                                                                                     |
| diss      | an object of class "dissimilarity" (see <a href="#">dissimilarity.object</a> ), representing the total dissimilarity matrix of the dataset.                                                                                                                                                                                                                                                                                                                                                                                             |
| data      | a matrix containing the original or standardized measurements, depending on the stand option of the function agnes. If a dissimilarity matrix was given as input structure, then this component is not available.                                                                                                                                                                                                                                                                                                                       |

## GENERATION

This class of objects is returned from [agnes](#).

## METHODS

The "agnes" class has methods for the following generic functions: `print`, `summary`, `plot`, and `as.dendrogram`.

In addition, `cutree(x, *)` can be used to "cut" the dendrogram in order to produce cluster assignments.

## INHERITANCE

The class "agnes" inherits from "twins". Therefore, the generic functions `pltree` and `as.hclust` are available for agnes objects. After applying `as.hclust()`, all *its* methods are available, of course.

## See Also

`agnes`, `diana`, `as.hclust`, `hclust`, `plot.agnes`, `twins.object`, `cutree`.

## Examples

```
data(agriculture)
ag.ag <- agnes(agriculture)
class(ag.ag)
pltree(ag.ag) # the dendrogram

cut the dendrogram -> get cluster assignments:
(ck3 <- cutree(ag.ag, k = 3))
(ch6 <- cutree(as.hclust(ag.ag), h = 6))
stopifnot(identical(unname(ch6), ck3))
```

---

agriculture

*European Union Agricultural Workforces*

---

## Description

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

## Usage

```
data(agriculture)
```

## Format

A data frame with 12 observations on 2 variables:

|        |   |         |                           |
|--------|---|---------|---------------------------|
| [ , 1] | x | numeric | per capita GNP            |
| [ , 2] | y | numeric | percentage in agriculture |

The row names of the data frame indicate the countries.

**Details**

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

**Source**

Eurostat (European Statistical Agency, 1994): *Cijfers en feiten: Een statistisch portret van de Europese Unie*.

**References**

see those in [agnes](#).

**See Also**

[agnes](#), [daisy](#), [diana](#).

**Examples**

```
data(agriculture)

Compute the dissimilarities using Euclidean metric and without
standardization
daisy(agriculture, metric = "euclidean", stand = FALSE)

2nd plot is similar to Figure 3 in Struyf et al (1996)
plot(pam(agriculture, 2))

Plot similar to Figure 7 in Struyf et al (1996)
Not run: plot(agnes(agriculture), ask = TRUE)

Plot similar to Figure 8 in Struyf et al (1996)
Not run: plot(diana(agriculture), ask = TRUE)
```

---

animals

*Attributes of Animals*

---

**Description**

This data set considers 6 binary attributes for 20 animals.

**Usage**

```
data(animals)
```

**Format**

A data frame with 20 observations on 6 variables:

|        |     |                |
|--------|-----|----------------|
| [ , 1] | war | warm-blooded   |
| [ , 2] | fly | can fly        |
| [ , 3] | ver | vertebrate     |
| [ , 4] | end | endangered     |
| [ , 5] | gro | live in groups |
| [ , 6] | hai | have hair      |

All variables are encoded as 1 = 'no', 2 = 'yes'.

**Details**

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

**Examples**

```
data(animals)
apply(animals,2, table) # simple overview

ma <- mona(animals)
ma
Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)
```

---

bannerplot

*Plot Banner (of Hierarchical Clustering)*

---

**Description**

Draws a “banner”, i.e. basically a horizontal [barplot](#) visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.

**Usage**

```
bannerplot(x, w = rev(x$height), fromLeft = TRUE,
 main=NULL, sub=NULL, xlab = "Height", adj = 0,
 col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
 rev.xax = !fromLeft, xax.pretty = TRUE,
 labels = NULL, nmax.lab = 35, max.strlen = 5,
 yax.do = axes && length(x$order) <= nmax.lab,
 yaxRight = fromLeft, y.mar = 2.4 + max.strlen/2.5, ...)
```

**Arguments**

|                         |                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | a list with components <code>order</code> , <code>order.lab</code> and <code>height</code> when <code>w</code> , the next argument is not specified.                              |
| <code>w</code>          | non-negative numeric vector of bar widths.                                                                                                                                        |
| <code>fromLeft</code>   | logical, indicating if the banner is from the left or not.                                                                                                                        |
| <code>main, sub</code>  | main and sub titles, see <a href="#">title</a> .                                                                                                                                  |
| <code>xlab</code>       | x axis label (with ‘correct’ default e.g. for <code>plot.agnes</code> ).                                                                                                          |
| <code>adj</code>        | passed to <a href="#">title</a> ( <code>main</code> , <code>sub</code> ) for string adjustment.                                                                                   |
| <code>col</code>        | vector of length 2, for two horizontal segments.                                                                                                                                  |
| <code>border</code>     | color for bar border; now defaults to background (no border).                                                                                                                     |
| <code>axes</code>       | logical indicating if axes (and labels) should be drawn at all.                                                                                                                   |
| <code>frame.plot</code> | logical indicating the banner should be framed; mainly used when <code>border = 0</code> (as per default).                                                                        |
| <code>rev.xax</code>    | logical indicating if the x axis should be reversed (as in <code>plot.diana</code> ).                                                                                             |
| <code>xax.pretty</code> | logical or integer indicating if <a href="#">pretty()</a> should be used for the x axis. <code>xax.pretty = FALSE</code> is mainly for back compatibility.                        |
| <code>labels</code>     | labels to use on y-axis; the default is constructed from <code>x</code> .                                                                                                         |
| <code>nmax.lab</code>   | integer indicating the number of labels which is considered too large for single-name labelling the banner plot.                                                                  |
| <code>max.strlen</code> | positive integer giving the length to which strings are truncated in banner plot labeling.                                                                                        |
| <code>yax.do</code>     | logical indicating if a y axis and banner labels should be drawn.                                                                                                                 |
| <code>yaxRight</code>   | logical indicating if the y axis is on the right or left.                                                                                                                         |
| <code>y.mar</code>      | positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also depend on the font. |
| <code>...</code>        | graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function.                                                                               |

**Note**

This is mainly a utility called from [plot.agnes](#), [plot.diana](#) and [plot.mona](#).

**Author(s)**

Martin Maechler (from original code of Kaufman and Rousseeuw).

**Examples**

```
data(agriculture)
bannerplot(agnes(agriculture), main = "Bannerplot")
```

---

chorSub*Subset of C-horizon of Kola Data*

---

## Description

This is a small rounded subset of the C-horizon data [chorizon](#) from package **mvoutlier**.

## Usage

```
data(chorSub)
```

## Format

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

## Details

This data set was produced from [chorizon](#) via these statements:

```
data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110]))[190:250,]
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub("_.*", "'", colnames(chorSub))
```

## Source

Kola Project (1993-1998)

## See Also

[chorizon](#) in package **mvoutlier** and other Kola data in the same package.

## Examples

```
data(chorSub)
summary(chorSub)
pairs(chorSub, gap= .1)# some outliers
```

|       |                               |
|-------|-------------------------------|
| clara | Clustering Large Applications |
|-------|-------------------------------|

---

**Description**

Computes a "clara" object, a [list](#) representing a clustering of the data into  $k$  clusters.

**Usage**

```
clara(x, k, metric = c("euclidean", "manhattan", "jaccard"),
 stand = FALSE, cluster.only = FALSE, samples = 5,
 sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,
 keep.data = medoids.x, rngR = FALSE, pamLike = FALSE, correct.d = TRUE)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric (or logical). Missing values (NAs) are allowed.                                                                                                                                                                                                    |
| <code>k</code>            | integer, the number of clusters. It is required that $0 < k < n$ where $n$ is the number of observations (i.e., $n = \text{nrow}(x)$ ).                                                                                                                                                                                                                                                        |
| <code>metric</code>       | character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean", "manhattan", "jaccard".<br>Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.                                                                                   |
| <code>stand</code>        | logical, indicating if the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.                                                                                                                  |
| <code>cluster.only</code> | logical; if true, only the clustering will be computed and returned, see details.                                                                                                                                                                                                                                                                                                              |
| <code>samples</code>      | integer, say $N$ , the number of samples to be drawn from the dataset. The default, $N = 5$ , is rather small for historical (and now back compatibility) reasons and we <i>recommend to set samples an order of magnitude larger</i> .                                                                                                                                                        |
| <code>sampsize</code>     | integer, say $j$ , the number of observations in each sample. <code>sampsize</code> should be higher than the number of clusters ( $k$ ) and at most the number of observations ( $n = \text{nrow}(x)$ ). While computational effort is proportional to $j^2$ , see note below, it may still be advisable to set $j = \text{sampsize}$ to a <i>larger</i> value than the (historical) default. |
| <code>trace</code>        | integer indicating a <i>trace level</i> for diagnostic output during the algorithm.                                                                                                                                                                                                                                                                                                            |
| <code>medoids.x</code>    | logical indicating if the medoids should be returned, identically to some rows of the input data <code>x</code> . If FALSE, <code>keep.data</code> must be false as well, and the medoid indices, i.e., row numbers of the medoids will still be returned (i.e., <code>med</code> component), and the algorithm saves space by needing one copy less of <code>x</code> .                       |
| <code>keep.data</code>    | logical indicating if the ( <i>scaled</i> if <code>stand</code> is true) data should be kept in the result. Setting this to FALSE saves memory (and hence time), but disables <a href="#">clusplot()</a> ing of the result. Use <code>medoids.x = FALSE</code> to save even more memory.                                                                                                       |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rngR</code>      | logical indicating if R's random number generator should be used instead of the primitive <code>clara()</code> -builtin one. If true, this also means that each call to <code>clara()</code> returns a different result – though only slightly different in good situations.                                                                                                                                                                                                                                                 |
| <code>pamLike</code>   | logical indicating if the “swap” phase (see <a href="#">pam</a> , in C code) should use the same algorithm as <a href="#">pam()</a> . Note that from Kaufman and Rousseeuw's description this <i>should</i> have been true always, but as the original Fortran code and the subsequent port to C has always contained a small one-letter change (a typo according to Martin Maechler) with respect to PAM, the default, <code>pamLike = FALSE</code> has been chosen to remain back compatible rather than “PAM compatible”. |
| <code>correct.d</code> | logical or integer indicating that—only in the case of NAs present in <code>x</code> —the correct distance computation should be used instead of the wrong formula which has been present in the original Fortran code and been in use up to early 2016. Because the new correct formula is not back compatible, for the time being, a warning is signalled in this case, unless the user explicitly specifies <code>correct.d</code> .                                                                                      |

### Details

`clara` (for “euclidean” and “manhattan”) is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other partitioning methods such as [pam](#), it can deal with much larger datasets. Internally, this is achieved by considering sub-datasets of fixed size (`sampsize`) such that the time and storage requirements become linear in  $n$  rather than quadratic.

Each sub-dataset is partitioned into  $k$  clusters using the same algorithm as in [pam](#).

Once  $k$  representative objects have been selected from the sub-dataset, each observation of the entire dataset is assigned to the nearest medoid.

The mean (equivalent to the sum) of the dissimilarities of the observations to their closest medoid is used as a measure of the quality of the clustering. The sub-dataset for which the mean (or sum) is minimal, is retained. A further analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then. Randomly drawn observations are added to this set until `sampsize` has been reached.

When `cluster.only` is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,

`clara(x, k, cluster.only=TRUE)` is the same as  
`clara(x, k)$clustering` but computed more efficiently.

### Value

If `cluster.only` is false (as by default), an object of class “`clara`” representing the clustering. See [clara.object](#) for details.

If `cluster.only` is true, the result is the “clustering”, an integer vector of length  $n$  with entries from  $1:k$ .

### Note

By default, the random sampling is implemented with a *very* simple scheme (with period  $2^{16} = 65536$ ) inside the Fortran code, independently of R's random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting `rngR = TRUE` which uses R's random number generators. Then, `clara()` results are made reproducible typically by using [set.seed\(\)](#) before calling `clara`.

The storage requirement of `clara` computation (for small  $k$ ) is about  $O(n \times p) + O(j^2)$  where  $j = \text{sampsize}$ , and  $(n, p) = \text{dim}(x)$ . The CPU computing time (again assuming small  $k$ ) is about  $O(n \times p \times j^2 \times N)$ , where  $N = \text{samples}$ .

For “small” datasets, the function `pam` can be used directly. What can be considered *small*, is really a function of available computing power, both memory (RAM) and speed. Originally (1990), “small” meant less than 100 observations; in 1997, the authors said “*small (say with fewer than 200 observations)*”; as of 2006, you can use `pam` with several thousand observations.

### Author(s)

Kaufman and Rousseeuw (see `agnes`), originally. Metric “jaccard”: Kamil Kozłowski (@ownedoutcomes.com) and Kamil Jadeszko. All arguments from trace on, and most R documentation and all tests by Martin Maechler.

### See Also

`agnes` for background and references; `clara.object`, `pam`, `partition.object`, `plot.partition`.

### Examples

```
generate 500 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(200,0,8), rnorm(200,0,8)),
 cbind(rnorm(300,50,8), rnorm(300,50,8)))
clarax <- clara(x, 2, samples=50)
clarax
clarax$clusinfo
using pamLike=TRUE gives the same (apart from the 'call'):
all.equal(clarax[-8],
 clara(x, 2, samples=50, pamLike = TRUE)[-8])
plot(clarax)

cluster.only = TRUE -- save some memory/time :
clclus <- clara(x, 2, samples=50, cluster.only = TRUE)
stopifnot(identical(clclus, clarax$clustering))

'xclara' is an artificial data set with 3 clusters of 1000 bivariate
objects each.
data(xclara)
(clx3 <- clara(xclara, 3))
"better" number of samples
cl.3 <- clara(xclara, 3, samples=100)
but that did not change the result here:
stopifnot(cl.3$clustering == clx3$clustering)
Plot similar to Figure 5 in Struyf et al (1996)
Not run: plot(clx3, ask = TRUE)

Try 100 times *different* random samples -- for reliability:
nSim <- 100
nCl <- 3 # = no.classes
set.seed(421)# (reproducibility)
cl <- matrix(NA,nrow(xclara), nSim)
for(i in 1:nSim)
 cl[,i] <- clara(xclara, nCl, medoids.x = FALSE, rngR = TRUE)$clustering
tcl <- apply(cl,1, tabulate, nbins = nCl)
those that are not always in same cluster (5 out of 3000 for this seed):
(iDoubt <- which(apply(tcl,2, function(n) all(n < nSim))))
if(length(iDoubt)) { # (not for all seeds)
```

```

tabD <- tcl[,iDoubt, drop=FALSE]
dimnames(tabD) <- list(cluster = paste(1:nCl), obs = format(iDoubt))
t(tabD) # how many times in which clusters
}

```

clara.object

*Clustering Large Applications (CLARA) Object***Description**

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from [clara](#).

**Value**

A legitimate clara object is a list with the following components:

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sample     | labels or case numbers of the observations in the best sample, that is, the sample used by the clara algorithm for the final partition.                                                                                                                                                                                                                                                                                                                                                                                                       |
| medoids    | the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from <code>clara(*, medoids.x=FALSE)</code> . Use the following <code>i.med</code> in that case.                                                                                                                                                                                                                                                                         |
| i.med      | the <i>indices</i> of the medoids above: <code>medoids &lt;- x[i.med,]</code> where <code>x</code> is the original data matrix in <code>clara(x,*)</code> .                                                                                                                                                                                                                                                                                                                                                                                   |
| clustering | the clustering vector, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| objective  | the objective function for the final clustering of the entire dataset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| clusinfo   | matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid. The last column is the maximal dissimilarity between the observations in the cluster and the cluster's medoid, divided by the minimal dissimilarity between the cluster's medoid and the medoid of any other cluster. If this ratio is small, the cluster is well-separated from the other clusters. |
| diss       | dissimilarity (maybe NULL), see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| silinfo    | list with silhouette width information for the best sample, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| call       | generating call, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| data       | matrix, possibly standardized, or NULL, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Methods, Inheritance**

The "clara" class has methods for the following generic functions: `print`, `summary`.

The class "clara" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a clara object.

**See Also**

[clara](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

## Description

`clusGap()` calculates a goodness of clustering measure, the “gap” statistic. For each number of clusters  $k$ , it compares  $\log(W(k))$  with  $E^*[\log(W(k))]$  where the latter is defined via bootstrapping, i.e., simulating from a reference ( $H_0$ ) distribution, a uniform distribution on the hypercube determined by the ranges of  $x$ , after first centering, and then `svd` (aka ‘PCA’)-rotating them when (as by default) `spaceH0 = "scaledPCA"`.

`maxSE(f, SE.f)` determines the location of the **maximum** of  $f$ , taking a “1-SE rule” into account for the `*SE*` methods. The default method `"firstSEmax"` looks for the smallest  $k$  such that its value  $f(k)$  is not more than 1 standard error away from the first local maximum. This is similar but not the same as `"Tibs2001SEmax"`, Tibshirani et al’s recommendation of determining the number of clusters from the gap statistics and their standard deviations.

## Usage

```
clusGap(x, FUNcluster, K.max, B = 100, d.power = 1,
 spaceH0 = c("scaledPCA", "original"),
 verbose = interactive(), ...)

maxSE(f, SE.f,
 method = c("firstSEmax", "Tibs2001SEmax", "globalSEmax",
 "firstmax", "globalmax"),
 SE.factor = 1)

S3 method for class 'clusGap'
print(x, method = "firstSEmax", SE.factor = 1, ...)

S3 method for class 'clusGap'
plot(x, type = "b", xlab = "k", ylab = expression(Gap[k]),
 main = NULL, do.arrows = TRUE,
 arrowArgs = list(col="red3", length=1/16, angle=90, code=3), ...)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | numeric matrix or <code>data.frame</code> .                                                                                                                                                                                                                                                                                                                                                 |
| <code>FUNcluster</code> | a <code>function</code> which accepts as first argument a (data) matrix like $x$ , second argument, say $k, k \geq 2$ , the number of clusters desired, and returns a <code>list</code> with a component named (or shortened to) <code>cluster</code> which is a vector of length $n = \text{nrow}(x)$ of integers in $1:k$ determining the clustering or grouping of the $n$ observations. |
| <code>K.max</code>      | the maximum number of clusters to consider, must be at least two.                                                                                                                                                                                                                                                                                                                           |
| <code>B</code>          | integer, number of Monte Carlo (“bootstrap”) samples.                                                                                                                                                                                                                                                                                                                                       |
| <code>d.power</code>    | a positive integer specifying the power $p$ which is applied to the euclidean distances ( <code>dist</code> ) before they are summed up to give $W(k)$ . The default, <code>d.power = 1</code> , corresponds to the “historical” R implementation, whereas <code>d.power = 2</code> corresponds to what Tibshirani et al had proposed. This was found by Juan Gonzalez, in 2016-02.         |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| arrowArgs              | a list of arguments passed to <code>arrows()</code> ; the default, notably angle and code, provide a style matching usual error bars.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

The main result `<res>$Tab[, "gap"]` of course is from bootstrapping aka Monte Carlo simulation and hence random, or equivalently, depending on the initial random seed (see `set.seed()`). On the other hand, in our experience, using  $B = 500$  gives quite precise results such that the gap plot is basically unchanged after an another run.

**Value**

clusGap(.) returns an object of S3 class "clusGap", basically a list with components

|            |                                                                                                                                                                                                                                                                                                                                                                               |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tab        | a matrix with <code>K.max</code> rows and 4 columns, named "logW", "E.logW", "gap", and "SE.sim", where $\text{gap} = E.\log W - \log W$ , and <code>SE.sim</code> corresponds to the standard error of gap, $\text{SE.sim}[k] = s_k$ , where $s_k := \sqrt{1 + 1/B} sd^*(gap_j)$ , and $sd^*(\cdot)$ is the standard deviation of the simulated ("bootstrapped") gap values. |
| call       | the clusGap(.) call.                                                                                                                                                                                                                                                                                                                                                          |

**Author(s)**

This function is originally based on the functions gap of former (Bioconductor) package **SAGx** by Per Broberg, gapStat() from former package **SLmisc** by Matthias Kohl and ideas from gap() and its methods of package **lga** by Justin Harrington.

The current implementation is by Martin Maechler.

The implementation of spaceH0 = "original" is based on code proposed by Juan Gonzalez.

`silhouette` for a much simpler less sophisticated goodness of clustering measure.

`cluster.stats()` in package **fpc** for alternative measures.

**Examples**

```
--- maxSE() methods -----
(mets <- eval(formals(maxSE)$method))
fk <- c(2,3,5,4,7,8,5,4)
sk <- c(1,1,2,1,1,3,1,1)/2
use plot.clusGap():
plot(structure(class="clusGap", list(Tab = cbind(gap=fk, SE.sim=sk)))
Note that 'firstmax' and 'globalmax' are always at 3 and 6 :
sapply(c(1/4, 1,2,4), function(SEf)
 sapply(mets, function(M) maxSE(fk, sk, method = M, SE.factor = SEf)))

--- clusGap() -----
```

```

ridiculously nicely separated clusters in 3 D :
x <- rbind(matrix(rnorm(150, sd = 0.1), ncol = 3),
 matrix(rnorm(150, mean = 1, sd = 0.1), ncol = 3),
 matrix(rnorm(150, mean = 2, sd = 0.1), ncol = 3),
 matrix(rnorm(150, mean = 3, sd = 0.1), ncol = 3))

Slightly faster way to use pam (see below)
pam1 <- function(x,k) list(cluster = pam(x,k, cluster.only=TRUE))

We do not recommend using hier.clustering here, but if you want,
there is factoextra::hcut () or a cheap version of it
hclusCut <- function(x, k, d.meth = "euclidean", ...)
 list(cluster = cutree(hclust(dist(x, method=d.meth), ...), k=k))

You can manually set it before running this : doExtras <- TRUE # or FALSE
if(!(exists("doExtras") && is.logical(doExtras)))
 doExtras <- cluster::doExtras()

if(doExtras) {
 ## Note we use B = 60 in the following examples to keep them "speedy".
 ## ---- rather keep the default B = 500 for your analysis!

 ## note we can pass 'nstart = 20' to kmeans() :
 gskmn <- clusGap(x, FUNcluster = kmeans, nstart = 20, K.max = 8, B = 60)
 gskmn #-> its print() method
 plot(gskmn, main = "clusGap(., FUNcluster = kmeans, n.start=20, B= 60)")
 set.seed(12); system.time(
 gsPam0 <- clusGap(x, FUNcluster = pam, K.max = 8, B = 60)
)
 set.seed(12); system.time(
 gsPam1 <- clusGap(x, FUNcluster = pam1, K.max = 8, B = 60)
)
 ## and show that it gives the "same":
 not.eq <- c("call", "FUNcluster"); n <- names(gsPam0)
 eq <- n[!(n %in% not.eq)]
 stopifnot(identical(gsPam1[eq], gsPam0[eq]))
 print(gsPam1, method="globalSEmax")
 print(gsPam1, method="globalmax")

 print(gsHc <- clusGap(x, FUNcluster = hclusCut, K.max = 8, B = 60))
}# end {doExtras}

gs.pam.RU <- clusGap(ruspini, FUNcluster = pam1, K.max = 8, B = 60)
gs.pam.RU
plot(gs.pam.RU, main = "Gap statistic for the 'ruspini' data")
mtext("k = 4 is best .. and k = 5 pretty close")

This takes a minute..
No clustering ==> k = 1 ("one cluster") should be optimal:
Z <- matrix(rnorm(256*3), 256,3)
gsP.Z <- clusGap(Z, FUNcluster = pam1, K.max = 8, B = 200)
plot(gsP.Z, main = "clusGap(<iid_rnorm_p=3>) ==> k = 1 cluster is optimal")
gsP.Z

```

---

clusplot*Bivariate Cluster Plot (of a Partitioning Object)*

---

### Description

Draws a 2-dimensional “clusplot” (clustering plot) on the current graphics device. The generic function has a default and a `partition` method.

### Usage

```
clusplot(x, ...)
```

```
S3 method for class 'partition'
clusplot(x, main = NULL, dist = NULL, ...)
```

### Arguments

|                   |                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | an R object, here, specifically an object of class “partition”, e.g. created by one of the functions <code>pam</code> , <code>clara</code> , or <code>fanny</code> .                                                                                           |
| <code>main</code> | title for the plot; when <code>NULL</code> (by default), a title is constructed, using <code>x\$call</code> .                                                                                                                                                  |
| <code>dist</code> | when <code>x</code> does not have a <code>diss</code> nor a <code>data</code> component, e.g., for <code>pam(dist(*), keep.diss=FALSE)</code> , <code>dist</code> must specify the dissimilarity for the <code>clusplot</code> .                               |
| <code>...</code>  | optional arguments passed to methods, notably the <code>clusplot.default</code> method (except for the <code>diss</code> one) may also be supplied to this function. Many graphical parameters (see <code>par</code> ) may also be supplied as arguments here. |

### Details

The `clusplot.partition()` method relies on `clusplot.default`.

If the clustering algorithms `pam`, `fanny` and `clara` are applied to a data matrix of observations-by-variables then a `clusplot` of the resulting clustering can always be drawn. When the data matrix contains missing values and the clustering is performed with `pam` or `fanny`, the dissimilarity matrix will be given as input to `clusplot`. When the clustering algorithm `clara` was applied to a data matrix with `NA`s then `clusplot()` will replace the missing values as described in `clusplot.default`, because a dissimilarity matrix is not available.

### Value

For the `partition` (and `default`) method: An invisible list with components `Distances` and `Shading`, as for `clusplot.default`, see there.

### Side Effects

a 2-dimensional `clusplot` is created on the current graphics device.

### See Also

`clusplot.default` for references; `partition.object`, `pam`, `pam.object`, `clara`, `clara.object`, `fanny`, `fanny.object`, `par`.

## Examples

```
For more, see ?clusplot.default

generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
 cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
clusplot(pam(x, 2))
add noise, and try again :
x4 <- cbind(x, rnorm(25), rnorm(25))
clusplot(pam(x4, 2))
```

clusplot.default

*Bivariate Cluster Plot (clusplot) Default Method*

## Description

Creates a bivariate plot visualizing a partition (clustering) of the data. All observation are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.

## Usage

```
Default S3 method:
clusplot(x, clus, diss = FALSE,
 s.x.2d = mkCheckX(x, diss), stand = FALSE,
 lines = 2, shade = FALSE, color = FALSE,
 labels= 0, plotchar = TRUE,
 col.p = "dark green", col.txt = col.p,
 col.clus = if(color) c(2, 4, 6, 3) else 5, cex = 1, cex.txt = cex,
 span = TRUE,
 add = FALSE,
 xlim = NULL, ylim = NULL,
 main = paste("CLUSPLOT(", deparse1(substitute(x)),")"),
 sub = paste("These two components explain",
 round(100 * var.dec, digits = 2), "% of the point variability."),
 xlab = "Component 1", ylab = "Component 2",
 verbose = getOption("verbose"),
 ...)
```

## Arguments

**x** matrix or data frame, or dissimilarity matrix, depending on the value of the `diss` argument.

In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message.

In case of a dissimilarity matrix, `x` is the output of `daisy` or `dist` or a symmetric matrix. Also, a vector of length  $n * (n - 1) / 2$  is allowed (where  $n$  is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clus     | a vector of length $n$ representing a clustering of $x$ . For each observation the vector lists the number or name of the cluster to which it has been assigned. clus is often the clustering component of the output of <a href="#">pam</a> , <a href="#">fanny</a> or <a href="#">clara</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| diss     | logical indicating if $x$ will be considered as a dissimilarity matrix or a matrix of observations by variables (see $x$ argument above).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| s.x.2d   | a <a href="#">list</a> with components named $x$ (a $n \times 2$ matrix; typically something like principal components of original data), <code>labs</code> and <code>var.dec</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| stand    | logical flag: if true, then the representations of the $n$ observations in the 2-dimensional plot are standardized.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| lines    | integer out of 0, 1, 2, used to obtain an idea of the distances between ellipses. The distance between two ellipses E1 and E2 is measured along the line connecting the centers $m1$ and $m2$ of the two ellipses.<br>In case E1 and E2 overlap on the line through $m1$ and $m2$ , no line is drawn. Otherwise, the result depends on the value of <code>lines</code> : If<br><b>lines = 0</b> , no distance lines will appear on the plot;<br><b>lines = 1</b> , the line segment between $m1$ and $m2$ is drawn;<br><b>lines = 2</b> , a line segment between the boundaries of E1 and E2 is drawn (along the line connecting $m1$ and $m2$ ).                                                                                                                                                                                                                                                                                                                                                     |
| shade    | logical flag: if TRUE, then the ellipses are shaded in relation to their density. The density is the number of points in the cluster divided by the area of the ellipse.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| color    | logical flag: if TRUE, then the ellipses are colored with respect to their density. With increasing density, the colors are light blue, light green, red and purple. To see these colors on the graphics device, an appropriate color scheme should be selected (we recommend a white background).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| labels   | integer code, currently one of 0,1,2,3,4 and 5. If<br><b>labels= 0</b> , no labels are placed in the plot;<br><b>labels= 1</b> , points and ellipses can be identified in the plot (see <a href="#">identify</a> );<br><b>labels= 2</b> , all points and ellipses are labelled in the plot;<br><b>labels= 3</b> , only the points are labelled in the plot;<br><b>labels= 4</b> , only the ellipses are labelled in the plot.<br><b>labels= 5</b> , the ellipses are labelled in the plot, and points can be identified.<br>The levels of the vector <code>clus</code> are taken as labels for the clusters. The labels of the points are the rownames of $x$ if $x$ is matrix like. Otherwise ( <code>diss = TRUE</code> ), $x$ is a vector, point labels can be attached to $x$ as a "Labels" attribute ( <code>attr(x, "Labels")</code> ), as is done for the output of <a href="#">daisy</a> .<br>A possible <a href="#">names</a> attribute of <code>clus</code> will not be taken into account. |
| plotchar | logical flag: if TRUE, then the plotting symbols differ for points belonging to different clusters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| span     | logical flag: if TRUE, then each cluster is represented by the ellipse with smallest area containing all its points. (This is a special case of the minimum volume ellipsoid.)<br>If FALSE, the ellipse is based on the mean and covariance matrix of the same points. While this is faster to compute, it often yields a much larger ellipse.<br>There are also some special cases: When a cluster consists of only one point, a tiny circle is drawn around it. When the points of a cluster fall on a straight line, <code>span=FALSE</code> draws a narrow ellipse around it and <code>span=TRUE</code> gives the exact line segment.                                                                                                                                                                                                                                                                                                                                                             |

|                           |                                                                                                                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>add</code>          | logical indicating if ellipses (and labels if <code>labels</code> is true) should be <i>added</i> to an already existing plot. If false, neither a <code>title</code> or sub title, see <code>sub</code> , is written. |
| <code>col.p</code>        | color code(s) used for the observation points.                                                                                                                                                                         |
| <code>col.txt</code>      | color code(s) used for the labels (if <code>labels</code> $\geq$ 2).                                                                                                                                                   |
| <code>col.clus</code>     | color code for the ellipses (and their labels); only one if <code>color</code> is false (as per default).                                                                                                              |
| <code>cex, cex.txt</code> | character <b>e</b> xpansion (size), for the point symbols and point labels, respectively.                                                                                                                              |
| <code>xlim, ylim</code>   | numeric vectors of length 2, giving the x- and y- ranges as in <code>plot.default</code> .                                                                                                                             |
| <code>main</code>         | main title for the plot; by default, one is constructed.                                                                                                                                                               |
| <code>sub</code>          | sub title for the plot; by default, one is constructed.                                                                                                                                                                |
| <code>xlab, ylab</code>   | x- and y- axis labels for the plot, with defaults.                                                                                                                                                                     |
| <code>verbose</code>      | a logical indicating, if there should be extra diagnostic output; mainly for ‘debugging’.                                                                                                                              |
| <code>...</code>          | Further graphical parameters may also be supplied, see <code>par</code> .                                                                                                                                              |

### Details

clusplot uses function calls `princomp`(\*, `cor` = (`ncol`(x) > 2)) or `cmdscale`(\*, `add`=TRUE), respectively, depending on `diss` being false or true. These functions are data reduction techniques to represent the data in a bivariate plot.

Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

### Value

An invisible list with components:

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Distances | When <code>lines</code> is 1 or 2 we obtain a k by k matrix (k is the number of clusters). The element in <code>[i, j]</code> is the distance between ellipse i and ellipse j. If <code>lines</code> = 0, then the value of this component is NA.                                                                                                                                                                                                           |
| Shading   | A vector of length k (where k is the number of clusters), containing the amount of shading per cluster. Let y be a vector where element i is the ratio between the number of points in cluster i and the area of ellipse i. When the cluster i is a line segment, <code>y[i]</code> and the density of the cluster are set to NA. Let z be the sum of all the elements of y without the NAs. Then we put <code>shading</code> = <code>y/z * 37 + 3</code> . |

### Side Effects

a visual display of the clustering is plotted on the current graphics device.

### Note

When we have 4 or fewer clusters, then the `color`=TRUE gives every cluster a different color. When there are more than 4 clusters, clusplot uses the function `pam` to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. `col.clus` specifies the colors used.

The `col.p` and `col.txt` arguments, added for R, are recycled to have length the number of observations. If `col.p` has more than one value, using `color` = TRUE can be confusing because of a mix of point and ellipse colors.

## Examples

```
plotting votes.diss(dissimilarity) in a bivariate plot and
partitioning into 2 clusters
data(votes.repub)
votes.diss <- daisy(votes.repub)
pamv <- pam(votes.diss, 2, diss = TRUE)
clusplot(pamv, shade = TRUE)
is the same as
votes.clus <- pamv$clustering
clusplot(votes.diss, votes.clus, diss = TRUE, shade = TRUE)
Now look at components 3 and 2 instead of 1 and 2:
str(cMDS <- cmdscale(votes.diss, k=3, add=TRUE))
clusplot(pamv, s.x.2d = list(x=cMDS$points[, c(3,2)],
 labs=rownames(votes.repub), var.dec=NA),
 shade = TRUE, col.p = votes.clus,
 sub="", xlab = "Component 3", ylab = "Component 2")

clusplot(pamv, col.p = votes.clus, labels = 4)# color points and label ellipses
"simple" cheap ellipses: larger than minimum volume:
here they are *added* to the previous plot:
clusplot(pamv, span = FALSE, add = TRUE, col.clus = "midnightblue")

Setting a small *label* size:
clusplot(votes.diss, votes.clus, diss = TRUE, labels = 3, cex.txt = 0.6)

if(dev.interactive()) { # uses identify() *interactively* :
 clusplot(votes.diss, votes.clus, diss = TRUE, shade = TRUE, labels = 1)
 clusplot(votes.diss, votes.clus, diss = TRUE, labels = 5)# ident. only points
}

plotting iris (data frame) in a 2-dimensional plot and partitioning
into 3 clusters.
data(iris)
iris.x <- iris[, 1:4]
cl3 <- pam(iris.x, 3)$clustering
op <- par(mfrow= c(2,2))
clusplot(iris.x, cl3, color = TRUE)
U <- par("usr")
zoom in :
rect(0,-1, 2,1, border = "orange", lwd=2)
clusplot(iris.x, cl3, color = TRUE, xlim = c(0,2), ylim = c(-1,1))
```

```

box(col="orange",lwd=2); mtext("sub region", font = 4, cex = 2)
or zoom out :
clusplot(iris.x, cl3, color = TRUE, xlim = c(-4,4), ylim = c(-4,4))
mtext("'super' region", font = 4, cex = 2)
rect(U[1],U[3], U[2],U[4], lwd=2, lty = 3)

reset graphics
par(op)

```

coef.hclust

*Agglomerative / Divisive Coefficient for 'hclust' Objects*

## Description

Computes the “agglomerative coefficient” (aka “divisive coefficient” for [diana](#)), measuring the clustering structure of the dataset.

For each observation  $i$ , denote by  $m(i)$  its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all  $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot.

coefHier() directly interfaces to the underlying C code, and “proves” that *only* object\$heights is needed to compute the coefficient.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

## Usage

```

coefHier(object)
coef.hclust(object, ...)
S3 method for class 'hclust'
coef(object, ...)
S3 method for class 'twins'
coef(object, ...)

```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                       |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object of class "hclust" or "twins", i.e., typically the result of <a href="#">hclust(.)</a> , <a href="#">agnes(.)</a> , or <a href="#">diana(.)</a> .<br>Since coef.hclust only uses object\$heights, and object\$merge, object can be any list-like object with appropriate merge and heights components.<br>For coefHier, even only object\$heights is needed. |
| ...    | currently unused potential further arguments                                                                                                                                                                                                                                                                                                                          |

## Value

a number specifying the *agglomerative* (or *divisive* for diana objects) coefficient as defined by Kaufman and Rousseeuw, see [agnes.object](#) \$ ac or [diana.object](#) \$ dc.

## Examples

```
data(agriculture)
aa <- agnes(agriculture)
coef(aa) # really just extracts aa$ac
coef(as.hclust(aa))# recomputes
coefHier(aa) # ditto
```

daisy

*Dissimilarity Matrix Calculation*

## Description

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types. In that case, or whenever `metric = "gower"` is set, a generalization of Gower's formula is used, see 'Details' below.

## Usage

```
daisy(x, metric = c("euclidean", "manhattan", "gower"),
 stand = FALSE, type = list(), weights = rep.int(1, p),
 warnBin = warnType, warnAsym = warnType, warnConst = warnType,
 warnType = TRUE)
```

## Arguments

- |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | numeric matrix or data frame, of dimension $n \times p$ , say. Dissimilarities will be computed between the rows of x. Columns of mode numeric (i.e. all columns when x is a matrix) will be recognized as interval scaled variables, columns of class factor will be recognized as nominal variables, and columns of class ordered will be recognized as ordinal variables. Other variable types should be specified with the type argument. Missing values (NAs) are allowed.                                                                                                                                                                           |
| metric | character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower".<br>Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.<br>"Gower's distance" is chosen by metric "gower" or automatically if some columns of x are not numeric. Also known as Gower's coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the "distance" between two units is the sum of all the variable-specific distances, see the details section. |
| stand  | logical flag: if TRUE, then the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.<br>If not all columns of x are numeric, stand will be ignored and Gower's standardization (based on the <a href="#">range</a> ) will be applied in any case, see argument metric, above, and the details section.                                                                                                                                                                   |
| type   | list for specifying some (or all) of the types of the variables (columns) in x. The list may contain the following components:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

"asymm" Asymmetric binary variable, aka "A" in result Types, see [dissimilarity.object](#).

"symm" Symmetric binary variable, aka "S".

"factor" Nominal – the default for [factor](#) variables, aka "N". When the factor has 2 levels, this is equivalent to type = "S" for a (symmetric) binary variable.

"ordered" Ordinal – the default for [ordered](#) (factor) variables, aka "O", see [dissimilarity.object](#).

"logratio" ratio scaled numeric variables that are to be logarithmically transformed ([log10](#)) and then treated as numeric ("I"): must be *positive* numeric variable.

"ordratio" "raTio"-like variable to be treated as [ordered](#) (using the factor codes `unclass(as.ordered(x[,j]))`), aka "T".

"numeric"/"integer" Interval scaled – the **default** for all numeric (incl integer) columns of `x`, aka "I" in result Types, see [dissimilarity.object](#).

Each component is a (character or numeric) vector, containing either the names or the numbers of the corresponding columns of `x`.

Variables not mentioned in type are interpreted as usual, see argument `x`, and also 'default' above. Consequently, the default type = `list()` may often be sufficient.

`weights` an optional numeric vector of length  $p(=ncol(x))$ ; to be used in "case 2" (mixed variables, or `metric = "gower"`), specifying a weight for each variable (`x[,k]`) instead of 1 in Gower's original formula.

`warnBin`, `warnAsym`, `warnConst` logicals indicating if the corresponding type checking warnings should be signalled (when found).

`warnType` logical indicating if *all* the type checking warnings should be active or not.

## Details

The original version of `daisy` is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to [dist](#) whose input must be numeric variables, the main feature of `daisy` is its ability to handle other variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If `x` contains any columns of these data-types, both arguments `metric` and `stand` will be ignored and Gower's coefficient will be used as the metric. This can also be activated for purely numeric data by `metric = "gower"`. With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable, after subtracting the minimum value; consequently the rescaled variable has range  $[0, 1]$ , exactly.

Note that setting the type to `symm` (symmetric binary) gives the same dissimilarities as using *nominal* (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that `daisy` signals a warning when 2-valued numerical variables do not have an explicit type specified, because the reference authors recommend to consider using "asymm"; the warning may be silenced by `warnBin = FALSE`.

In the `daisy` algorithm, missing values in a row of `x` are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled (and metric is *not* "gower"), the metric is "euclidean", and  $n_g$  is the number of columns in which neither row  $i$  and  $j$  have NAs, then the dissimilarity  $d(i,j)$  returned is  $\sqrt{p/n_g}$  ( $p = \text{ncol}(x)$ ) times the Euclidean distance between the two vectors of length  $n_g$  shortened to exclude NAs. The rule is similar for the "manhattan" metric, except that the coefficient is  $p/n_g$ . If  $n_g = 0$ , the dissimilarity is NA.
2. When some variables have a type other than interval scaled, or if metric = "gower" is specified, the dissimilarity between two rows is the weighted mean of the contributions of each variable. Specifically,

$$d_{ij} = d(i, j) = \frac{\sum_{k=1}^p w_k \delta_{ij}^{(k)} d_{ij}^{(k)}}{\sum_{k=1}^p w_k \delta_{ij}^{(k)}}.$$

In other words,  $d_{ij}$  is a weighted mean of  $d_{ij}^{(k)}$  with weights  $w_k \delta_{ij}^{(k)}$ , where  $w_k = \text{weights}[k]$ ,  $\delta_{ij}^{(k)}$  is 0 or 1, and  $d_{ij}^{(k)}$ , the  $k$ -th variable contribution to the total distance, is a distance between  $x[i, k]$  and  $x[j, k]$ , see below.

The 0-1 weight  $\delta_{ij}^{(k)}$  becomes zero when the variable  $x[, k]$  is missing in either or both rows ( $i$  and  $j$ ), or when the variable is asymmetric binary and both values are zero. In all other situations it is 1.

The contribution  $d_{ij}^{(k)}$  of a nominal or binary variable to the total dissimilarity is 0 if both values are equal, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Note that "standard scoring" is applied to ordinal variables, i.e., they are replaced by their integer codes 1:K. Note that this is not the same as using their ranks (since there typically are ties).

As the individual contributions  $d_{ij}^{(k)}$  are in  $[0, 1]$ , the dissimilarity  $d_{ij}$  will remain in this range.

If all weights  $w_k \delta_{ij}^{(k)}$  are zero, the dissimilarity is set to NA.

## Value

an object of class "dissimilarity" containing the dissimilarities among the rows of  $x$ . This is typically the input for the functions `pam`, `fanny`, `agnes` or `diana`. For more details, see [dissimilarity.object](#).

## Background

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

## Author(s)

Anja Struyf, Mia Hubert, and Peter and Rousseeuw, for the original version.

Martin Maechler improved the NA handling and type specification checking, and extended functionality to metric = "gower" and the optional weights argument.

[dissimilarity.object](#), [dist](#), [pam](#), [fanny](#), [clara](#), [agnes](#), [diana](#).

**Examples**

```
data(agriculture)
Example 1 in ref:
Dissimilarities using Euclidean metric and without standardization
d.agr <- daisy(agriculture, metric = "euclidean", stand = FALSE)
d.agr
as.matrix(d.agr)[,"DK"] # via as.matrix.dist(.)
compare with
as.matrix(daisy(agriculture, metric = "gower"))

Example 2 in reference, extended --- different ways of "mixed" / "gower":

example(flower) # -> data(flower) *and* provide 'flowerN'

summary(d0 <- daisy(flower)) # -> the first 3 {0,1} treated as *N*ominal
summary(dS123 <- daisy(flower, type = list(symm = 1:3))) # first 3 treated as *S*ymmetric
stopifnot(dS123 == d0) # i.e., *S*ymmetric <==> *N*ominal {for 2-level factor}
summary(dNS123 <- daisy(flowerN, type = list(symm = 1:3)))
stopifnot(dS123 == d0)
by default, however ...
summary(dA123 <- daisy(flowerN)) # .. all 3 logicals treated *A*symmetric binary (w/ warning)
summary(dA3 <- daisy(flower, type = list(asymm = 3)))
summary(dA13 <- daisy(flower, type = list(asymm = c(1, 3), ordratio = 7)))
Mixing variable *names* and column numbers (failed in the past):
summary(df13 <- daisy(flower, type = list(asymm = c("V1", "V3"), symm = 2,
 ordratio = 7, logratio = 8)))

If we'd treat the first 3 as simple {0,1}
Nflow <- flower
Nflow[,1:3] <- lapply(flower[,1:3], function(f) as.integer(as.character(f)))
summary(dN <- daisy(Nflow)) # w/ warning: treated binary .. 1:3 as interval
Still, using Euclidean/Manhattan distance for {0-1} *is* identical to treating them as "N" :
stopifnot(dN == d0)
stopifnot(dN == daisy(Nflow, type = list(symm = 1:3))) # or as "S"
```

---

diana

---

*D*ivisive *A*NAlysis Clustering

---

**Description**

Computes a divisive hierarchical clustering of the dataset returning an object of class *diana*.

**Usage**

```
diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE,
 stop.at.k = FALSE,
 keep.diss = n < 100, keep.data = !diss, trace.lev = 0)
```

## Arguments

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                    | <p>data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) <i>are</i> allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are <i>not</i> allowed.</p> |
| <code>diss</code>                 | <p>logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>metric</code>               | <p>character string specifying the metric to be used for calculating dissimilarities between observations.</p> <p>The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>                                                                                                                                                                                                                                                                                                              |
| <code>stand</code>                | <p>logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>                                                                                                                                                                                                                                                                                                                                              |
| <code>stop.at.k</code>            | <p>logical or integer, FALSE by default. Otherwise must be integer, say <math>k</math>, in <math>\{1, 2, \dots, n\}</math>, specifying that the <code>diana</code> algorithm should stop early. Non-default NOT YET IMPLEMENTED.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>keep.diss, keep.data</code> | <p>logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>trace.lev</code>            | <p>integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Details

`diana` is fully described in chapter 6 of Kaufman and Rousseeuw (1990). It is probably unique in computing a divisive hierarchy, whereas most other software for hierarchical clustering is agglomerative. Moreover, `diana` provides (a) the divisive coefficient (see `diana.object`) which measures the amount of clustering structure found; and (b) the banner, a novel graphical display (see `plot.diana`).

The `diana`-algorithm constructs a hierarchy of clusterings, starting with one large cluster containing all  $n$  observations. Clusters are divided until each cluster contains only a single observation. At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the largest dissimilarity between any two of its observations.)

To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which has the largest average dissimilarity to the other observations of the selected cluster). This observation initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are closer to the "splinter group" than to the "old party". The result is a division of the selected cluster into two new clusters.

**Value**

an object of class "diana" representing the clustering; this class has methods for the following generic functions: `print`, `summary`, `plot`.

Further, the class "diana" inherits from "twins". Therefore, the generic function `pltree` can be used on a diana object, and `as.hclust` and `as.dendrogram` methods are available.

A legitimate diana object is a list with the following components:

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>order</code>     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>order.lab</code> | a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.                                                                                                                                                                                                                                                                                                                                                        |
| <code>height</code>    | a vector with the diameters of the clusters prior to splitting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>dc</code>        | the divisive coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $d(i)$ the diameter of the last cluster to which it belongs (before being split off as a single observation), divided by the diameter of the whole dataset. The dc is the average of all $1 - d(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot. Because dc grows with the number of observations, this measure should not be used to compare datasets of very different sizes. |
| <code>merge</code>     | an $(n-1)$ by 2 matrix, where $n$ is the number of observations. Row $i$ of <code>merge</code> describes the split at step $n-i$ of the clustering. If a number $j$ in row $r$ is negative, then the single observation $ j $ is split off at stage $n-r$ . If $j$ is positive, then the cluster that will be splitted at stage $n-j$ (described by row $j$ ), is split off at stage $n-r$ .                                                                                                                                                   |
| <code>diss</code>      | an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>data</code>      | a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.                                                                                                                                                                                                                                                                                                   |

**See Also**

`agnes` also for background and references; `cutree` (and `as.hclust`) for grouping extraction; `daisy`, `dist`, `plot.diana`, `twins.object`.

**Examples**

```
data(votes.repub)
dv <- diana(votes.repub, metric = "manhattan", stand = TRUE)
print(dv)
plot(dv) #-> plot.diana() {w/ its own help + examples}

Cut into 2 groups:
dv2 <- cutree(as.hclust(dv), k = 2)
table(dv2) # 8 and 42 group members
rownames(votes.repub)[dv2 == 1]

For two groups, does the metric matter ?
dv0 <- diana(votes.repub, stand = TRUE) # default: Euclidean
dv.2 <- cutree(as.hclust(dv0), k = 2)
```

```

table(dv2 == dv.2)## identical group assignments

str(as.dendrogram(dv0)) # {via as.dendrogram.twins() method}

data(agriculture)
Plot similar to Figure 8 in ref
Not run: plot(diana(agriculture), ask = TRUE)

```

---

dissimilarity.object    *Dissimilarity Matrix Object*

---

## Description

Objects of class "dissimilarity" representing the dissimilarity matrix of a dataset.

## Value

The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object, is called *do*, and *n* the number of observations, i.e.,  $n \leftarrow \text{attr}(\text{do}, "Size")$ , then for  $i < j \leq n$ , the dissimilarity between (row) *i* and *j* is  $\text{do}[n*(i-1) - i*(i-1)/2 + j - i]$ . The length of the vector is  $n * (n - 1)/2$ , i.e., of order  $n^2$ .

"dissimilarity" objects also inherit from class [dist](#) and can use *dist* methods, in particular, [as.matrix](#), such that  $d_{ij}$  from above is just `as.matrix(do)[i, j]`.

The object has the following attributes:

|            |                                                                                                                                                                                                                                                                                                                                                        |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Size       | the number of observations in the dataset.                                                                                                                                                                                                                                                                                                             |
| Metric     | the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".                                                                                                                                                           |
| Labels     | optionally, contains the labels, if any, of the observations of the dataset.                                                                                                                                                                                                                                                                           |
| NA.message | optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.                                                                                                                                                                                                                         |
| Types      | when a mixed metric was used, the types for each variable as one-letter codes, see also type in <a href="#">daisy()</a> :<br>A: Asymmetric binary<br>S: Symmetric binary<br>N: Nominal (factor)<br>O: Ordinal (ordered factor)<br>I: Interval scaled, possibly after log transform "logratio" (numeric)<br>T: raTio treated as <a href="#">ordered</a> |

## GENERATION

[daisy](#) returns this class of objects. Also the functions *pam*, *clara*, *fanny*, *agnes*, and *diana* return a dissimilarity object, as one component of their return objects.

## METHODS

The "dissimilarity" class has methods for the following generic functions: *print*, *summary*.

**See Also**

[daisy](#), [dist](#), [pam](#), [clara](#), [fanny](#), [agnes](#), [diana](#).

---

ellipsoidhull

---

*Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set*

---

**Description**

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.

**Usage**

```
ellipsoidhull(x, tol=0.01, maxit=5000,
 ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)
S3 method for class 'ellipsoid'
print(x, digits = max(1, getOption("digits") - 2), ...)
```

**Arguments**

**x** the  $n$   $p$ -dimensional points as numeric  $n \times p$  matrix.

**tol** convergence tolerance for Titterton’s algorithm. Setting this to much smaller values may drastically increase the number of iterations needed, and you may want to increase **maxit** as well.

**maxit** integer giving the maximal number of iteration steps for the algorithm.

**ret.wt, ret.sqdist, ret.pr** logicals indicating if additional information should be returned, **ret.wt** specifying the *weights*, **ret.sqdist** the *squared distances* and **ret.pr** the final **probabilities** in the algorithms.

**digits, ...** the usual arguments to [print](#) methods.

**Details**

The “spanning ellipsoid” algorithm is said to stem from Titterton(1976), in Pison et al (1999) who use it for [clusplot.default](#).

The problem can be seen as a special case of the “Min.Vol.” ellipsoid of which a more flexible and general implementation is [cov.mve](#) in the MASS package.

**Value**

an object of class “ellipsoid”, basically a [list](#) with several components, comprising at least

**cov**  $p \times p$  covariance matrix description the ellipsoid.

**loc**  $p$ -dimensional location of the ellipsoid center.

**d2** average squared radius. Further,  $d2 = t^2$ , where  $t$  is “the value of a t-statistic on the ellipse boundary” (from [ellipse](#) in the [ellipse](#) package), and hence, more usefully,  $d2 = qchisq(alpha, df = p)$ , where  $alpha$  is the confidence level for  $p$ -variate normally distributed data with location and covariance **loc** and **cov** to lie inside the ellipsoid.

|            |                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------|
| wt         | the vector of weights iff <code>ret.wt</code> was true.                                                   |
| sqdist     | the vector of squared distances iff <code>ret.sqdist</code> was true.                                     |
| prob       | the vector of algorithm probabilities iff <code>ret.pr</code> was true.                                   |
| it         | number of iterations used.                                                                                |
| tol, maxit | just the input argument, see above.                                                                       |
| eps        | the achieved tolerance which is the maximal squared radius minus $p$ .                                    |
| ierr       | error code as from the algorithm; 0 means <i>ok</i> .                                                     |
| conv       | logical indicating if the converged. This is defined as <code>it &lt; maxit &amp;&amp; ierr == 0</code> . |

### Author(s)

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying original code.

### See Also

`predict.ellipsoid` which is also the `predict` method for `ellipsoid` objects.  
`volume.ellipsoid` for an example of ‘manual’ `ellipsoid` object construction;  
further `ellipse` from package `ellipse` and `ellipsePoints` from package `sfsmisc`.  
`chull` for the convex hull, `clusplot` which makes use of this; `cov.mve`.

### Examples

```
x <- rnorm(100)
xy <- unname(cbind(x, rnorm(100) + 2*x + 10))
exy. <- ellipsoidhull(xy)
exy. # >> calling print.ellipsoid()

plot(xy, main = "ellipsoidhull(<Gauss data>) -- 'spanning points'")
lines(predict(exy.), col="blue")
points(rbind(exy.$loc), col = "red", cex = 3, pch = 13)

exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sqdist = TRUE)
str(exy) # had small 'tol', hence many iterations
(ii <- which(zapsmall(exy $ wt) > 1e-6))
--> only about 4 to 6 "spanning ellipsoid" points
round(exy$wt[ii],3); sum(exy$wt[ii]) # weights summing to 1
points(xy[ii,], pch = 21, cex = 2,
 col="blue", bg = adjustcolor("blue",0.25))
```

## Description

Computes a fuzzy clustering of the data into  $k$  clusters.

## Usage

```
fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
 metric = c("euclidean", "manhattan", "SqEuclidean"),
 stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
 keep.diss = !diss && !cluster.only && n < 100,
 keep.data = !diss && !cluster.only,
 maxit = 500, tol = 1e-15, trace.lev = 0)
```

## Arguments

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x        | <p>data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p> |
| k        | integer giving the desired number of clusters. It is required that $0 < k < n/2$ where $n$ is the number of observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| diss     | logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then <code>x</code> is assumed to be a dissimilarity matrix. If FALSE, then <code>x</code> is treated as a matrix of observations by variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| memb.exp | number $r$ strictly larger than 1 specifying the <i>membership exponent</i> used in the fit criterion; see the ‘Details’ below. Default: 2 which used to be hardwired inside FANNY.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| metric   | <p>character string specifying the metric to be used for calculating dissimilarities between observations. Options are "euclidean" (default), "manhattan", and "SqEuclidean". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences, and "SqEuclidean", the <i>squared</i> euclidean distances are sum-of-squares of differences. Using this last option is equivalent (but somewhat slower) to computing so called “fuzzy C-means”.</p> <p>If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>                                                                                    |
| stand    | logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.                                                                                                                                                                                                                                                                                                                             |

|                                   |                                                                                                                                                                                                                                                       |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>iniMem.p</code>             | numeric $n \times k$ matrix or NULL (by default); can be used to specify a starting membership matrix, i.e., a matrix of non-negative numbers, each row summing to one.                                                                               |
| <code>cluster.only</code>         | logical; if true, no silhouette information will be computed and returned, see details.                                                                                                                                                               |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to FALSE can give smaller results and hence also save memory allocation <i>time</i> .                                         |
| <code>maxit, tol</code>           | maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults <code>maxit</code> = 500 and <code>tol</code> = 1e-15 used to be hardwired inside the algorithm. |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.                                                                                  |

## Details

In a fuzzy clustering, each observation is “spread out” over the various clusters. Denote by  $u_{iv}$  the membership of observation  $i$  to cluster  $v$ .

The memberships are nonnegative, and for a fixed observation  $i$  they sum to 1. The particular method `fanny` stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in [daisy](#)) and has been extended by Martin Maechler to allow user specified `memb.exp`, `iniMem.p`, `maxit`, `tol`, etc.

Fanny aims to minimize the objective function

$$\sum_{v=1}^k \frac{\sum_{i=1}^n \sum_{j=1}^n u_{iv}^r u_{jv}^r d(i, j)}{2 \sum_{j=1}^n u_{jv}^r}$$

where  $n$  is the number of observations,  $k$  is the number of clusters,  $r$  is the membership exponent `memb.exp` and  $d(i, j)$  is the dissimilarity between observations  $i$  and  $j$ .

Note that  $r \rightarrow 1$  gives increasingly crisper clusterings whereas  $r \rightarrow \infty$  leads to complete fuzzyness. K&R(1990), p.191 note that values too close to 1 can lead to slow convergence. Further note that even the default,  $r = 2$  can lead to complete fuzzyness, i.e., memberships  $u_{iv} \equiv 1/k$ . In that case a warning is signalled and the user is advised to chose a smaller `memb.exp` ( $= r$ ).

Compared to other fuzzy clustering methods, `fanny` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the spherical cluster assumption; (c) it provides a novel graphical display, the silhouette plot (see [plot.partition](#)).

## Value

an object of class “fanny” representing the clustering. See [fanny.object](#) for details.

## See Also

[agnes](#) for background and references; [fanny.object](#), [partition.object](#), [plot.partition](#), [daisy](#), [dist](#).

## Examples

```
generate 10+15 objects in two clusters, plus 3 objects lying
between those clusters.
x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
 cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
 cbind(rnorm(3,3.2,0.5), rnorm(3,3.2,0.5)))
fannyx <- fanny(x, 2)
Note that observations 26:28 are "fuzzy" (closer to # 2):
fannyx
summary(fannyx)
plot(fannyx)

(fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crispier' for obs. 26:28
(fanny(x, 2, memb.exp = 3)) # more fuzzy in general

data(ruspini)
f4 <- fanny(ruspini, 4)
stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
plot(f4, which = 1)
Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

fanny.object

*Fuzzy Analysis (FANNY) Object*

## Description

The objects of class "fanny" represent a fuzzy clustering of a dataset.

## Value

A legitimate fanny object is a list with the following components:

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| membership  | matrix containing the memberships for each pair consisting of an observation and a cluster.                                                                                                                                                                                                                                                                                                                                                                                                               |
| memb.exp    | the membership exponent used in the fitting criterion.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| coeff       | Dunn's partition coefficient $F(k)$ of the clustering, where $k$ is the number of clusters. $F(k)$ is the sum of all <i>squared</i> membership coefficients, divided by the number of observations. Its value is between $1/k$ and 1.<br>The normalized form of the coefficient is also given. It is defined as $(F(k) - 1/k)/(1 - 1/k)$ , and ranges between 0 and 1. A low value of Dunn's coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering. |
| clustering  | the clustering vector of the nearest crisp clustering, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                             |
| k.crisp     | integer ( $\leq k$ ) giving the number of <i>crisp</i> clusters; can be less than $k$ , where it's recommended to decrease memb.exp.                                                                                                                                                                                                                                                                                                                                                                      |
| objective   | named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance tol used.                                                                                                                                                                                                                                                                                                                                                       |
| convergence | named vector with iterations, the number of iterations needed and converged indicating if the algorithm converged (in maxit iterations within convergence tolerance tol).                                                                                                                                                                                                                                                                                                                                 |

- diss            an object of class "dissimilarity", see [partition.object](#).
- call           generating call, see [partition.object](#).
- silinfo        list with silhouette information of the nearest crisp clustering, see [partition.object](#).
- data           matrix, possibly standardized, or NULL, see [partition.object](#).

**GENERATION**

These objects are returned from [fanny](#).

**METHODS**

The "fanny" class has methods for the following generic functions: print, summary.

**INHERITANCE**

The class "fanny" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a fanny object.

**See Also**

[fanny](#), [print.fanny](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

---

|        |                               |
|--------|-------------------------------|
| flower | <i>Flower Characteristics</i> |
|--------|-------------------------------|

---

**Description**

8 characteristics for 18 popular flowers.

**Usage**

data(flower)

**Format**

A data frame with 18 observations on 8 variables:

|           |         |            |
|-----------|---------|------------|
| [ , "V1"] | factor  | winters    |
| [ , "V2"] | factor  | shadow     |
| [ , "V3"] | factor  | tubers     |
| [ , "V4"] | factor  | color      |
| [ , "V5"] | ordered | soil       |
| [ , "V6"] | ordered | preference |
| [ , "V7"] | numeric | height     |
| [ , "V8"] | numeric | distance   |

- V1** winters, is binary and indicates whether the plant may be left in the garden when it freezes.
- V2** shadow, is binary and shows whether the plant needs to stand in the shadow.
- V3** tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow in any other way.

- V4** color, is nominal and specifies the flower's color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).
- V5** soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.
- V6** preference, is ordinal and gives someone's preference ranking going from 1 to 18.
- V7** height, is interval scaled, the plant's height in centimeters.
- V8** distance, is interval scaled, the distance in centimeters that should be left between the plants.

## References

Struyf, Hubert and Rousseeuw (1996), see [agnes](#).

## Examples

```
data(flower)
str(flower) # factors, ordered, numeric

"Nicer" version (less numeric more self explainable) of 'flower':
flowerN <- flower
colnames(flowerN) <- c("winters", "shadow", "tubers", "color",
 "soil", "preference", "height", "distance")
for(j in 1:3) flowerN[,j] <- (flowerN[,j] == "1")
levels(flowerN$color) <- c("1" = "white", "2" = "yellow", "3" = "pink",
 "4" = "red", "5" = "blue")[levels(flowerN$color)]
levels(flowerN$soil) <- c("1" = "dry", "2" = "normal", "3" = "wet")[levels(flowerN$soil)]
flowerN

==> example(daisy) on how it is used

lower.to.upper.tri.inds

*Permute Indices for Triangular Matrices*

---

## Description

Compute index vectors for extracting or reordering of lower or upper triangular matrices that are stored as contiguous vectors.

## Usage

```
lower.to.upper.tri.inds(n)
upper.to.lower.tri.inds(n)
```

## Arguments

n                      integer larger than 1.

## Value

integer vector containing a permutation of 1:N where  $N = n(n-1)/2$ .

## See Also

[upper.tri](#), [lower.tri](#) with a related purpose.

## Examples

```
m5 <- matrix(NA,5,5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.inds(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.inds(5); m

stopifnot(lower.to.upper.tri.inds(2) == 1,
 lower.to.upper.tri.inds(3) == 1:3,
 upper.to.lower.tri.inds(3) == 1:3,
 sort(upper.to.lower.tri.inds(5)) == 1:10,
 sort(lower.to.upper.tri.inds(6)) == 1:15)
```

medoids

---

*Compute pam-consistent Medoids from Clustering*

---

## Description

Given a data matrix or dissimilarity  $x$  for say  $n$  observational units and a clustering, compute the [pam\(\)](#)-consistent medoids.

## Usage

```
medoids(x, clustering, diss = inherits(x, "dist"), USE.NAMES = FALSE, ...)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                                                                                      |

| <code>x</code>          | Either a data matrix or data frame, or dissimilarity matrix or object, see also <a href="#">pam</a> .                                                                                                                                                                                                                                                                                |
| <code>clustering</code> | an integer vector of length $n$ , the number of observations, giving for each observation the number ('id') of the cluster to which it belongs. In other words, <code>clustering</code> has values from $1:k$ where $k$ is the number of clusters, see also <a href="#">partition.object</a> and <a href="#">cutree()</a> , for examples where such clustering vectors are computed. |
| <code>diss</code>       | see also <a href="#">pam</a> .                                                                                                                                                                                                                                                                                                                                                       |
| <code>USE.NAMES</code>  | a logical, typical false, passed to the <a href="#">vapply()</a> call computing the medoids.                                                                                                                                                                                                                                                                                         |
| <code>...</code>        | optional further argument passed to <a href="#">pam(xj, k=1, ...)</a> , notably <code>metric</code> , or <code>variant="f_5"</code> to use a faster algorithm, or <code>trace.lev = k</code> .                                                                                                                                                                                       |

## Value

a numeric vector of length

## Author(s)

Martin Maechler, after being asked how [pam\(\)](#) could be used instead of [kmeans\(\)](#), starting from a previous clustering.

## See Also

[pam](#), [kmeans](#). Further, [cutree\(\)](#) and [agnes](#) (or [hclust](#)).

## Examples

```
From example(agnes):
data(votes.repub)
agn1 <- agnes(votes.repub, metric = "manhattan", stand = TRUE)
agn2 <- agnes(daisy(votes.repub), diss = TRUE, method = "complete")
agnS <- agnes(votes.repub, method = "flexible", par.method = 0.625)

for(k in 2:11) {
 print(table(cl.k <- cutree(agnS, k=k)))
 stopifnot(length(cl.k) == nrow(votes.repub), 1 <= cl.k, cl.k <= k, table(cl.k) >= 2)
 m.k <- medoids(votes.repub, cl.k)
 cat("k =", k, "; sort(medoids) = "); dput(sort(m.k), control={})
}
```

---

mona

*MONothetic Analysis Clustering of Binary Variables*

---

## Description

Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

## Usage

```
mona(x, trace.lev = 0)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | data matrix or data frame in which each row corresponds to an observation, and each column corresponds to a variable. All variables must be binary. A limited number of missing values (NAs) is allowed. Every observation must have at least one value different from <a href="#">NA</a> . No variable should have half of its values missing. There must be at least one variable which has no missing values. A variable with all its non-missing values identical is not allowed. |
| <code>trace.lev</code> | logical or integer indicating if (and how much) the algorithm should produce progress output.                                                                                                                                                                                                                                                                                                                                                                                         |

## Details

`mona` is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is “monothetic” in the sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical methods (including `agnes` and `diana`) are “polythetic”, i.e. they use all variables together.

The `mona`-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters are divided until all observations in the same cluster have identical values for all variables.

At each stage, all clusters are divided according to the values of one variable. A cluster is divided into one cluster with all observations having value 1 for that variable, and another cluster with all observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the other variables, according to the observations in the cluster to be splitted. The association between variables  $f$  and  $g$  is given by  $a(f,g)*d(f,g) - b(f,g)*c(f,g)$ , where  $a(f,g)$ ,  $b(f,g)$ ,  $c(f,g)$ , and  $d(f,g)$  are the numbers in the contingency table of  $f$  and  $g$ . [That is,  $a(f,g)$  (resp.  $d(f,g)$ ) is the number of

observations for which  $f$  and  $g$  both have value 0 (resp. value 1);  $b(f,g)$  (resp.  $c(f,g)$ ) is the number of observations for which  $f$  has value 0 (resp. 1) and  $g$  has value 1 (resp. 0).] The total association of a variable  $f$  is the sum of its associations to all variables.

## Value

an object of class "mona" representing the clustering. See [mona.object](#) for details.

## Missing Values (NAs)

The mona-algorithm requires “pure” 0-1 values. However, `mona(x)` allows  $x$  to contain (not too many) NAs. In a preliminary step, these are “imputed”, i.e., all missing values are filled in. To do this, the same measure of association between variables is used as in the algorithm. When variable  $f$  has missing values, the variable  $g$  with the largest absolute association to  $f$  is looked up. When the association between  $f$  and  $g$  is positive, any missing value of  $f$  is replaced by the value of  $g$  for the same observation. If the association between  $f$  and  $g$  is negative, then any missing value of  $f$  is replaced by the value of  $1-g$  for the same observation.

## Note

In **cluster** versions before 2.0.6, the algorithm entered an infinite loop in the boundary case of one variable, i.e., `ncol(x) == 1`, which currently signals an error (because the algorithm now in C, has not correctly taken account of this special case).

## See Also

[agnes](#) for background and references; [mona.object](#), [plot.mona](#).

## Examples

```
data(animals)
ma <- mona(animals)
ma
Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

One place to see if/how error messages are *translated* (to 'de' / 'pl'):
ani.NA <- animals; ani.NA[4,] <- NA
aniNA <- within(animals, { end[2:9] <- NA })
aniN2 <- animals; aniN2[cbind(1:6, c(3, 1, 4:6, 2))] <- NA
ani.non2 <- within(animals, end[7] <- 3)
ani.idNA <- within(animals, end[!is.na(end)] <- 1)
try(mona(ani.NA)) ## error: .. object with all values missing
try(mona(aniNA)) ## error: .. more than half missing values
try(mona(aniN2)) ## error: all have at least one missing
try(mona(ani.non2)) ## error: all must be binary
try(mona(ani.idNA)) ## error: ditto
```

|-------------|------------------------------------------|
| mona.object | <i>Monothetic Analysis (MONA) Object</i> |
|-------------|------------------------------------------|

---

**Description**

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from [mona](#).

**Value**

A legitimate mona object is a list with the following components:

|           |                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data      | matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.                                          |
| order     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.                     |
| order.lab | a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled. |
| variable  | vector of length n-1 where n is the number of observations, specifying the variables used to separate the observations of order.                                          |
| step      | vector of length n-1 where n is the number of observations, specifying the separation steps at which the observations of order are separated.                             |

**METHODS**

The "mona" class has methods for the following generic functions: print, summary, plot.

**See Also**

[mona](#) for examples etc, [plot.mona](#).

|-----|------------------------------------|
| pam | <i>Partitioning Around Medoids</i> |
|-----|------------------------------------|

---

**Description**

Partitioning (clustering) of the data into k clusters "around medoids", a more robust version of K-means.

**Usage**

```
pam(x, k, diss = inherits(x, "dist"),
 metric = c("euclidean", "manhattan"),
 medoids = if(is.numeric(nstart)) "random",
 nstart = if(variant == "faster") 1 else NA,
 stand = FALSE, cluster.only = FALSE,
 do.swap = TRUE,
 keep.diss = !diss && !cluster.only && n < 100,
```

```
keep.data = !diss && !cluster.only,
variant = c("original", "o_1", "o_2", "f_3", "f_4", "f_5", "faster"),
pamonce = FALSE, trace.lev = 0)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                    | <p>data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric (or logical). Missing values (NAs) <i>are</i> allowed—as long as every pair of observations has at least one case not missing.</p> <p>In case of a dissimilarity matrix, x is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are <i>not</i> allowed.</p> |
| k                    | positive integer specifying the number of clusters, less than the number of observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| diss                 | logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then x will be considered as a dissimilarity matrix. If FALSE, then x will be considered as a matrix of observations by variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| metric               | <p>character string specifying the metric to be used for calculating dissimilarities between observations.</p> <p>The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If x is already a dissimilarity matrix, then this argument will be ignored.</p>                                                                                                                                                                                                                                                                                                                                                                                      |
| medoids              | NULL (default) or length-k vector of integer indices (in 1:n) specifying initial medoids instead of using the ‘ <i>build</i> ’ algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| nstart               | used only when <code>medoids = "random"</code> : specifies the <i>number</i> of random “starts”; this argument corresponds to the one of <code>kmeans()</code> (from R’s package <b>stats</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| stand                | logical; if true, the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If x is already a dissimilarity matrix, then this argument will be ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| cluster.only         | logical; if true, only the clustering will be computed and returned, see details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| do.swap              | logical indicating if the <b>swap</b> phase should happen. The default, TRUE, correspond to the original algorithm. On the other hand, the <b>swap</b> phase is much more computer intensive than the <b>build</b> one for large <i>n</i> , so can be skipped by <code>do.swap = FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| keep.diss, keep.data | logicals indicating if the dissimilarities and/or input data x should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| pamonce              | logical or integer in 0:6 specifying algorithmic short cuts as proposed by Reynolds et al. (2006), and Schubert and Rousseeuw (2019, 2021) see below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| variant              | a <a href="#">character</a> string denoting the variant of PAM algorithm to use; a more self-documenting version of <code>pamonce</code> which should be used preferably; note that                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

"faster" not only uses `pamonce = 6` but also `nstart = 1` and hence medoids = "random" by default.

`trace.lev` integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default 0 does not print anything; higher values print increasingly more.

## Details

The basic pam algorithm is fully described in chapter 2 of Kaufman and Rousseeuw(1990). Compared to the k-means approach in `kmeans`, the function `pam` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see `plot.partition`) (d) it allows to select the number of clusters using `mean(silhouette(pr)[, "sil_width"])` on the result `pr <- pam(. .)`, or directly its component `pr$silinfo$avg.width`, see also [pam.object](#).

When `cluster.only` is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,

`pam(x,k, cluster.only=TRUE)` is the same as  
`pam(x,k)$clustering` but computed more efficiently.

The pam-algorithm is based on the search for  $k$  representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of  $k$  medoids,  $k$  clusters are constructed by assigning each observation to the nearest medoid. The goal is to find  $k$  representative objects which minimize the sum of the dissimilarities of the observations to their closest representative object.

By default, when medoids are not specified, the algorithm first looks for a good initial set of medoids (this is called the **build** phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid (i.e. a 'swap') that will decrease the objective (this is called the **swap** phase).

When the medoids are specified (or randomly generated), their order does *not* matter; in general, the algorithms have been designed to not depend on the order of the observations.

The `pamonce` option, new in `cluster` 1.14.2 (Jan. 2012), has been proposed by Matthias Studer, University of Geneva, based on the findings by Reynolds et al. (2006) and was extended by Erich Schubert, TU Dortmund, with the FastPAM optimizations.

The default FALSE (or integer 0) corresponds to the original "swap" algorithm, whereas `pamonce = 1` (or TRUE), corresponds to the first proposal .... and `pamonce = 2` additionally implements the second proposal as well.

The key ideas of 'FastPAM' (Schubert and Rousseeuw, 2019) are implemented except for the linear approximate build as follows:

`pamonce = 3`: reduces the runtime by a factor of  $O(k)$  by exploiting that points cannot be closest to all current medoids at the same time.

`pamonce = 4`: additionally allows executing multiple swaps per iteration, usually reducing the number of iterations.

`pamonce = 5`: adds minor optimizations copied from the `pamonce = 2` approach, and is expected to be the fastest of the 'FastPam' variants included.

'FasterPAM' (Schubert and Rousseeuw, 2021) is implemented via

`pamonce = 6`: execute each swap which improves results immediately, and hence typically multiple swaps per iteration; this swapping algorithm runs in  $O(n^2)$  rather than  $O(n(n-k)k)$  time which is much faster for all but small  $k$ .

In addition, ‘FasterPAM’ uses *random* initialization of the medoids (instead of the ‘*build*’ phase) to avoid the  $O(n^2k)$  initialization cost of the build algorithm. In particular for large  $k$ , this yields a much faster algorithm, while preserving a similar result quality.

One may decide to use *repeated* random initialization by setting `nstart > 1`.

### Value

an object of class “pam” representing the clustering. See [?pam.object](#) for details.

### Note

For large datasets, pam may need too much memory or too much computation time since both are  $O(n^2)$ . Then, [clara\(\)](#) is preferable, see its documentation.

There is hard limit currently,  $n \leq 65536$ , at  $2^{16}$  because for larger  $n$ ,  $n(n-1)/2$  is larger than the maximal integer (`.Machine$integer.max =  $2^{31} - 1$` ).

### Author(s)

Kaufman and Rousseeuw’s original Fortran code was translated to C and augmented in several ways, e.g. to allow `cluster.only=TRUE` or `do.swap=FALSE`, by Martin Maechler.

Matthias Studer, Univ.Geneva provided the pamonce (1 and 2) implementation.

Erich Schubert, TU Dortmund contributed the pamonce (3 to 6) implementation.

### Examples

```
generate 25 objects, divided into 2 clusters.
set.seed(17) # to get reproducible data:
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
 cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
pamx <- pam(x, 2)
pamx # Medoids: '9' and '15' ...
summary(pamx)
plot(pamx)
stopifnot(pamx$id.med == c(9, 15))
stopifnot(identical(pamx$clustering, rep(1:2, c(10, 15))))

use obs. 1 & 16 as starting medoids -- same result (for seed above, *and* typically) :
(p2m <- pam(x, 2, medoids = c(1,16)))
```

```
no _build_ *and* no _swap_ phase: just cluster all obs. around (1, 16):
p2.s <- pam(x, 2, medoids = c(1,16), do.swap = FALSE)
p2.s
keep_nms <- setdiff(names(pamx), c("call", "objective"))# .$objective["build"] differ
stopifnot(p2.s$id.med == c(1,16), # of course
 identical(pamx[keep_nms],
 p2m[keep_nms]))

p3m <- pam(x, 3, trace.lev = 2)
rather stupid initial medoids:
(p3m. <- pam(x, 3, medoids = 3:1, trace.lev = 1))

pam(daisy(x, metric = "manhattan"), 2, diss = TRUE)

data(ruspini)
Plot similar to Figure 4 in Stryuf et al (1996)
Not run: plot(pam(ruspini, 4), ask = TRUE)
```

pam.object

*Partitioning Around Medoids (PAM) Object*

## Description

The objects of class "pam" represent a partitioning of a dataset into clusters.

## Value

A legitimate pam object is a [list](#) with the following components:

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| medoids    | the medoids or representative objects of the clusters. If a dissimilarity matrix was given as input to pam, then a vector of numbers or labels of observations is given, else medoids is a <a href="#">matrix</a> with in each row the coordinates of one medoid.                                                                                                                                                                                                                                                       |
| id.med     | integer vector of <i>indices</i> giving the medoid observation numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| clustering | the clustering vector, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| objective  | the objective function after the first and second step of the pam algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| isolation  | vector with length equal to the number of clusters, specifying which clusters are isolated clusters (L- or L*-clusters) and which clusters are not isolated.<br>A cluster is an L*-cluster iff its diameter is smaller than its separation. A cluster is an L-cluster iff for each observation i the maximal dissimilarity between i and any other observation of the cluster is smaller than the minimal dissimilarity between i and any observation of another cluster. Clearly each L*-cluster is also an L-cluster. |
| clusinfo   | matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid, the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).                                            |
| silinfo    | list with silhouette width information, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|      |                                                                    |
|------|--------------------------------------------------------------------|
| diss | dissimilarity (maybe NULL), see <a href="#">partition.object</a> . |
| call | generating call, see <a href="#">partition.object</a> .            |
| data | (possibly standardized) see <a href="#">partition.object</a> .     |

## GENERATION

These objects are returned from [pam](#).

## METHODS

The "pam" class has methods for the following generic functions: print, summary.

## INHERITANCE

The class "pam" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a pam object.

## See Also

[pam](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

## Examples

```
Use the silhouette widths for assessing the best number of clusters,
following a one-dimensional example from Christian Hennig :
##
x <- c(rnorm(50), rnorm(50,mean=5), rnorm(30,mean=15))
asw <- numeric(20)
Note that "k=1" won't work!
for (k in 2:20)
 asw[k] <- pam(x, k) $ silinfo $ avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters:", k.best, "\n")

plot(1:20, asw, type= "h", main = "pam() clustering assessment",
 xlab= "k (# clusters)", ylab = "average silhouette width")
axis(1, k.best, paste("best",k.best,sep="\n"), col = "red", col.axis = "red")
```

---

partition.object

*Partitioning Object*

---

## Description

The objects of class "partition" represent a partitioning of a dataset into clusters.

## Value

a "partition" object is a list with the following (and typically more) components:

|            |                                                                                                                                                                        |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clustering | the clustering vector. An integer vector of length $n$ , the number of observations, giving for each observation the number ('id') of the cluster to which it belongs. |
| call       | the matched <a href="#">call</a> generating the object.                                                                                                                |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| silinfo   | <p>a list with all <i>silhouette</i> information, only available when the number of clusters is non-trivial, i.e., <math>1 &lt; k &lt; n</math> and then has the following components, see <a href="#">silhouette</a></p> <p><b>widths</b> an (n x 3) matrix, as returned by <a href="#">silhouette()</a>, with for each observation <i>i</i> the cluster to which <i>i</i> belongs, as well as the neighbor cluster of <i>i</i> (the cluster, not containing <i>i</i>, for which the average dissimilarity between its observations and <i>i</i> is minimal), and the silhouette width <math>s(i)</math> of the observation.</p> <p><b>clus.avg.widths</b> the average silhouette width per cluster.</p> <p><b>avg.width</b> the average silhouette width for the dataset, i.e., simply the average of <math>s(i)</math> over all observations <i>i</i>.</p> <p>This information is also needed to construct a <i>silhouette plot</i> of the clustering, see <a href="#">plot.partition</a>.</p> <p>Note that avg.width can be maximized over different clusterings (e.g. with varying number of clusters) to choose an <i>optimal</i> clustering.</p> |
| objective | value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| diss      | an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for clara).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| data      | a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## GENERATION

These objects are returned from pam, clara or fanny.

## METHODS

The "partition" class has a method for the following generic functions: plot, clusplot.

## INHERITANCE

The following classes inherit from class "partition": "pam", "clara" and "fanny".

See [pam.object](#), [clara.object](#) and [fanny.object](#) for details.

## See Also

[pam](#), [clara](#), [fanny](#).

---

plantTraits

*Plant Species Traits Data*

---

## Description

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive)

**Usage**

```
data(plantTraits)
```

**Format**

A data frame with 136 observations on the following 31 variables.

`pdias` Diaspore mass (mg)

`longindex` Seed bank longevity

`durflow` Flowering duration

`height` Plant height, an ordered factor with levels 1 < 2 < ... < 8.

`begflow` Time of first flowering, an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9

`mycor` Mycorrhizas, an ordered factor with levels 0never < 1 sometimes < 2always

`vegaer` aerial vegetative propagation, an ordered factor with levels 0never < 1 present but limited < 2important.

`vegsout` underground vegetative propagation, an ordered factor with 3 levels identical to `vegaer` above.

`autopoll` selfing pollination, an ordered factor with levels 0never < 1rare < 2 often < 3 the rule

`insects` insect pollination, an ordered factor with 5 levels 0 < ... < 4.

`wind` wind pollination, an ordered factor with 5 levels 0 < ... < 4.

`lign` a binary factor with levels 0:1, indicating if plant is woody.

`piq` a binary factor indicating if plant is thorny.

`ros` a binary factor indicating if plant is rosette.

`semiros` semi-rosette plant, a binary factor (0: no; 1: yes).

`leafy` leafy plant, a binary factor.

`suman` summer annual, a binary factor.

`winan` winter annual, a binary factor.

`monocarp` monocarpic perennial, a binary factor.

`polycarp` polycarpic perennial, a binary factor.

`seasaes` seasonal aestival leaves, a binary factor.

`seashiv` seasonal hibernal leaves, a binary factor.

`seasver` seasonal vernal leaves, a binary factor.

`everalw` leaves always evergreen, a binary factor.

`everparti` leaves partially evergreen, a binary factor.

`elaio` fruits with an elaiosome (dispersed by ants), a binary factor.

`endozoo` endozoochorous fruits, a binary factor.

`epizoo` epizoochorous fruits, a binary factor.

`aquat` aquatic dispersal fruits, a binary factor.

`windgl` wind dispersed fruits, a binary factor.

`unsp` unspecialized mechanism of seed dispersal, a binary factor.

**Details**

Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by insects but sometimes self-pollination can occurred.

## Examples

```
data(plantTraits)

Calculation of a dissimilarity matrix
library(cluster)
dai.b <- daisy(plantTraits,
 type = list(ordratio = 4:11, symm = 12:13, asymm = 14:31))

Hierarchical classification
agn.trts <- agnes(dai.b, method="ward")
plot(agn.trts, which.plots = 2, cex= 0.6)
plot(agn.trts, which.plots = 1)
cutree6 <- cutree(agn.trts, k=6)
cutree6

Principal Coordinate Analysis
cmds dai.b <- cmdscale(dai.b, k=6)
plot(cmdsdai.b[, 1:2], asp = 1, col = cutree6)
```

---

plot.agnes

*Plots of an Agglomerative Hierarchical Clustering*

---

## Description

Creates plots for visualizing an agnes object.

## Usage

```
S3 method for class 'agnes'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
 sub = paste("Agglomerative Coefficient = ", round(x$ac, digits = 2)),
 adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

## Arguments

|             |                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | an object of class "agnes", typically created by <a href="#">agnes(.)</a> .                                                                                                               |
| ask         | logical; if true and which.plots is NULL, plot.agnes operates in interactive mode, via <a href="#">menu</a> .                                                                             |
| which.plots | integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a <i>banner</i> plot or 2 for a dendrogram or "clustering tree". |
| main, sub   | main and sub title for the plot, with convenient defaults. See documentation for these arguments in <a href="#">plot.default</a> .                                                        |
| adj         | for label adjustment in <a href="#">bannerplot()</a> .                                                                                                                                    |

|            |                                                                                                                                                                                        |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nmax.lab   | integer indicating the number of labels which is considered too large for single-name labelling the banner plot.                                                                       |
| max.strlen | positive integer giving the length to which strings are truncated in banner plot labeling.                                                                                             |
| xax.pretty | logical or integer indicating if <code>pretty(*, n = xax.pretty)</code> should be used for the x axis. <code>xax.pretty = FALSE</code> is for back compatibility.                      |
| ...        | graphical parameters (see <code>par</code> ) may also be supplied and are passed to <code>bannerplot()</code> or <code>pltree()</code> (see <code>pltree.twins</code> ), respectively. |

## Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.agnes` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the `agnes` algorithm, and the numbers in the height vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call `bannerplot` and `pltree()`, i.e., its method `pltree.twins`, respectively.

directly with corresponding arguments, e.g., `xlab` or `ylab`.

## Side Effects

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:

Banner  
Clustering tree

## Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For the dendrogram, more flexibility than via `pltree()` is provided by `dg <- as.dendrogram(x)` and plotting `dg` via `plot.dendrogram`.

## Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.diana` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the diana algorithm, and the numbers in the height vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.

## Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Banner  
Clustering tree

## Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

## References

see those in [plot.agnes](#).

## See Also

[diana](#), [diana.object](#), [twins.object](#), [par](#).

## Examples

```
example(diana)# -> dv <- diana(...)

plot(dv, which.plots = 1, nmax.lab = 100)

wider labels :
op <- par(mar = par("mar") + c(0, 2, 0,0))
plot(dv, which.plots = 1, nmax.lab = 100, max.strlen = 12)
par(op)
```

---

plot.mona

*Banner of Monothetic Divisive Hierarchical Clusterings*

---

## Description

Creates the banner of a mona object.

**Usage**

```
S3 method for class 'mona'
plot(x, main = paste("Banner of ", deparse1(x$call)),
 sub = NULL, xlab = "Separation step",
 col = c(2,0), axes = TRUE, adj = 0,
 nmax.lab = 35, max.strlen = 5, ...)
```

**Arguments**

|                                      |                                                                                                              |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>x</code>                       | an object of class "mona", typically created by <code>mona(.)</code> .                                       |
| <code>main</code> , <code>sub</code> | main and sub titles for the plot, with convenient defaults. See documentation in <code>plot.default</code> . |
| <code>xlab</code>                    | x axis label, see <code>title</code> .                                                                       |
| <code>col</code> , <code>adj</code>  | graphical parameters passed to <code>bannerplot()</code> .                                                   |
| <code>axes</code>                    | logical, indicating if (labeled) axes should be drawn.                                                       |
| <code>nmax.lab</code>                | integer indicating the number of labels which is considered too large for labeling.                          |
| <code>max.strlen</code>              | positive integer giving the length to which strings are truncated in labeling.                               |
| <code>...</code>                     | further graphical arguments are passed to <code>bannerplot()</code> and <code>text</code> .                  |

**Details**

Plots the separation step at which clusters are splitted. The observations are given in the order found by the mona algorithm, the numbers in the step vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

**Side Effects**

A banner is plotted on the current graphics device.

**Note**

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

**References**

see those in `plot.agnes`.

**See Also**

`mona`, `mona.object`, `par`.

plot.partition

*Plot of a Partition of the Data Set***Description**

Creates plots for visualizing a partition object.

**Usage**

```
S3 method for class 'partition'
plot(x, ask = FALSE, which.plots = NULL,
 nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL,
 stand = FALSE, lines = 2,
 shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE,
 span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)
```

**Arguments**

|                                                                           |                                                                                                                                                                                                                      |
|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                                                                         | an object of class "partition", typically created by the functions <a href="#">pam</a> , <a href="#">clara</a> , or <a href="#">fanny</a> .                                                                          |
| ask                                                                       | logical; if true and which.plots is NULL, plot.partition operates in interactive mode, via <a href="#">menu</a> .                                                                                                    |
| which.plots                                                               | integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a <i>clusplot</i> or 2 for <i>silhouette</i> .                                              |
| nmax.lab                                                                  | integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.                                                                                                  |
| max.strlen                                                                | positive integer giving the length to which strings are truncated in silhouette plot labeling.                                                                                                                       |
| data                                                                      | numeric matrix with the scaled data; per default taken from the partition object x, but can be specified explicitly.                                                                                                 |
| dist                                                                      | when x does not have a diss component as for <a href="#">pam</a> (*, keep.diss=FALSE), dist must be the dissimilarity if a <i>clusplot</i> is desired.                                                               |
| stand, lines, shade, color, labels, plotchar, span, xlim, ylim, main, ... | All optional arguments available for the <a href="#">clusplot.default</a> function (except for the diss one) and graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function. |

**Details**

When ask= TRUE, rather than producing each plot sequentially, plot.partition displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call `par(ask= TRUE)` before invoking the plot command.

The *clusplot* of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see [clusplot.partition](#) for more details).

The *silhouette plot* of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation *i*, a bar is drawn, representing its silhouette width *s(i)*, see [silhouette](#) for details. Observations are grouped per cluster, starting with cluster 1 at the top. Observations with a large *s(i)* (almost 1) are very well clustered, a small *s(i)*

(around 0) means that the observation lies between two clusters, and observations with a negative  $s(i)$  are probably placed in the wrong cluster.

A clustering can be performed for several values of  $k$  (the number of clusters). Finally, choose the value of  $k$  with the largest overall average silhouette width.

### Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Clusplot

Silhouette plot

### Note

In the silhouette plot, observation labels are only printed when the number of observations is less than `nmax.lab` (40, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For more flexibility, use `plot(silhouette(x), ...)`, see [plot.silhouette](#).

### References

Rousseeuw, P.J. (1987) Silhouettes: A graphical aid to the interpretation and validation of cluster analysis. *J. Comput. Appl. Math.*, **20**, 53–65.

Further, the references in [plot.agnes](#).

### See Also

[partition.object](#), [clusplot.partition](#), [clusplot.default](#), [pam](#), [pam.object](#), [clara](#), [clara.object](#), [fanny](#), [fanny.object](#), [par](#).

### Examples

```
generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
 cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
plot(pam(x, 2))

Save space not keeping data in clus.object, and still clusplot() it:
data(xclara)
cx <- clara(xclara, 3, keep.data = FALSE)
cx$data # is NULL
plot(cx, data = xclara)
```

### Description

`pmtree()` Draws a clustering tree (“dendrogram”) on the current graphics device. We provide the `twins` method draws the tree of a `twins` object, i.e., hierarchical clustering, typically resulting from [agnes\(\)](#) or [diana\(\)](#).

## Usage

```
pltree(x, ...)
S3 method for class 'twins'
pltree(x, main = paste("Dendrogram of ", deparse1(x$call)),
 labels = NULL, ylab = "Height", ...)
```

## Arguments

|                     |                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | in general, an R object for which a <code>pltree</code> method is defined; specifically, an object of class "twins", typically created by either <a href="#">agnes()</a> or <a href="#">diana()</a> . |
| <code>main</code>   | main title with a sensible default.                                                                                                                                                                   |
| <code>labels</code> | labels to use; the default is constructed from <code>x</code> .                                                                                                                                       |
| <code>ylab</code>   | label for y-axis.                                                                                                                                                                                     |
| <code>...</code>    | graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function.                                                                                                   |

## Details

Creates a plot of a clustering tree given a twins object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being splitted.

Note that currently the method function simply calls `plot(as.hclust(x), ...)`, which dispatches to [plot.hclust\(..\)](#). If more flexible plots are needed, consider `xx <- as.dendrogram(as.hclust(x))` and plotting `xx`, see [plot.dendrogram](#).

## Value

a NULL value is returned.

## See Also

[agnes](#), [agnes.object](#), [diana](#), [diana.object](#), [hclust](#), [par](#), [plot.agnes](#), [plot.diana](#).

## Examples

```
data(votes.repub)
agn <- agnes(votes.repub)
pltree(agn)

dagn <- as.dendrogram(as.hclust(agn))
dagn2 <- as.dendrogram(as.hclust(agn), hang = 0.2)
op <- par(mar = par("mar") + c(0,0,0, 2)) # more space to the right
plot(dagn2, horiz = TRUE)
plot(dagn, horiz = TRUE, center = TRUE,
 nodePar = list(lab.cex = 0.6, lab.col = "forest green", pch = NA),
 main = deparse(agn$call))
par(op)
```

---

 pluton

---

*Isotopic Composition Plutonium Batches*

---

### Description

The pluton data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.

### Usage

```
data(pluton)
```

### Format

This data frame contains the following columns:

**Pu238** the percentages of  $^{238}\text{Pu}$ , always less than 2 percent.

**Pu239** the percentages of  $^{239}\text{Pu}$ , typically between 60 and 80 percent (from neutron capture of Uranium,  $^{238}\text{U}$ ).

**Pu240** percentage of the plutonium 240 isotope.

**Pu241** percentage of the plutonium 241 isotope.

### Details

Note that the percentage of plutonium~242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

### Source

Available as 'pluton.dat' from the archive of the University of Antwerpen, '[.../datasets/clusplot-examples.tar.gz](#)', no longer available.

### References

Rousseeuw, P.J. and Kaufman, L and Trauwaert, E. (1996) Fuzzy clustering using scatter matrices, *Computational Statistics and Data Analysis* **23**(1), 135–151.

### Examples

```
data(pluton)

hist(apply(pluton,1,sum), col = "gray") # between 94% and 100%
pu5 <- pluton
pu5$Pu242 <- 100 - apply(pluton,1,sum) # the remaining isotope.
pairs(pu5)
```

|                   |                                             |
|-------------------|---------------------------------------------|
| predict.ellipsoid | <i>Predict Method for Ellipsoid Objects</i> |
|-------------------|---------------------------------------------|

---

## Description

Compute points on the ellipsoid boundary, mostly for drawing.

## Usage

```
predict.ellipsoid(object, n.out=201, ...)
S3 method for class 'ellipsoid'
predict(object, n.out=201, ...)
ellipsoidPoints(A, d2, loc, n.half = 201)
```

## Arguments

|               |                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object        | an object of class ellipsoid, typically from <a href="#">ellipsoidhull()</a> ; alternatively any list-like object with proper components, see details below. |
| n.out, n.half | half the number of points to create.                                                                                                                         |
| A, d2, loc    | arguments of the auxiliary ellipsoidPoints, see below.                                                                                                       |
| ...           | passed to and from methods.                                                                                                                                  |

## Details

Note ellipsoidPoints is the workhorse function of predict.ellipsoid a standalone function and method for ellipsoid objects, see [ellipsoidhull](#). The class of object is not checked; it must solely have valid components loc (length  $p$ ), the  $p \times p$  matrix cov (corresponding to A) and d2 for the center, the shape (“covariance”) matrix and the squared average radius (or distance) or [qchisq](#)(\*, p) quantile.

Unfortunately, this is only implemented for  $p = 2$ , currently; contributions for  $p \geq 3$  are *very welcome*.

## Value

a numeric matrix of dimension  $2 \times n.out$  times  $p$ .

## See Also

[ellipsoidhull](#), [volume.ellipsoid](#).

## Examples

```
see also example(ellipsoidhull)

Robust vs. L.S. covariance matrix
set.seed(143)
x <- rt(200, df=3)
y <- 3*x + rt(200, df=2)
plot(x,y, main="non-normal data (N=200)")
mtext("with classical and robust cov.matrix ellipsoids")
X <- cbind(x,y)
```

```

C.ls <- cov(X) ; m.ls <- colMeans(X)
d2.99 <- qchisq(0.99, df = 2)
lines(ellipsoidPoints(C.ls, d2.99, loc=m.ls), col="green")
if(require(MASS)) {
 Cxy <- cov.rob(cbind(x,y))
 lines(ellipsoidPoints(Cxy$cov, d2 = d2.99, loc=Cxy$center), col="red")
}# MASS

```

---

print.agnes

---

*Print Method for AGNES Objects*

---

### Description

Prints the call, agglomerative coefficient, ordering of objects and distances between merging clusters ('Height') of an agnes object.

This is a method for the generic [print\(\)](#) function for objects inheriting from class agnes, see [agnes.object](#).

### Usage

```
S3 method for class 'agnes'
print(x, ...)
```

### Arguments

x                      an agnes object.  
 ...                    potential further arguments (required by generic).

### See Also

[summary.agnes](#) producing more output; [agnes](#), [agnes.object](#), [print](#), [print.default](#).

---

print.clara

---

*Print Method for CLARA Objects*

---

### Description

Prints the best sample, medoids, clustering vector and objective function of clara object.

This is a method for the function [print\(\)](#) for objects inheriting from class [clara](#).

### Usage

```
S3 method for class 'clara'
print(x, ...)
```

### Arguments

x                      a clara object.  
 ...                    potential further arguments (require by generic).

**See Also**

[summary.clara](#) producing more output; [clara](#), [clara.object](#), [print](#), [print.default](#).

---

print.diana

---

*Print Method for DIANA Objects*

---

**Description**

Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a diana object.

This is a method for the function [print\(\)](#) for objects inheriting from class [diana](#).

**Usage**

```
S3 method for class 'diana'
print(x, ...)
```

**Arguments**

|     |                                                   |
|-----|---------------------------------------------------|
| x   | a diana object.                                   |
| ... | potential further arguments (require by generic). |

**See Also**

[diana](#), [diana.object](#), [print](#), [print.default](#).

---

print.dissimilarity

---

*Print and Summary Methods for Dissimilarity Objects*

---

**Description**

Print or summarize the distances and the attributes of a dissimilarity object.

These are methods for the functions [print\(\)](#) and [summary\(\)](#) for dissimilarity objects. See [print](#), [print.default](#), or [summary](#) for the general behavior of these.

**Usage**

```
S3 method for class 'dissimilarity'
print(x, diag = NULL, upper = NULL,
 digits = getOption("digits"), justify = "none", right = TRUE, ...)
S3 method for class 'dissimilarity'
summary(object,
 digits = max(3, getOption("digits") - 2), ...)
S3 method for class 'summary.dissimilarity'
print(x, ...)
```

**Arguments**

x, object      a dissimilarity object or a summary.dissimilarity one for print.summary.dissimilarity().

digits          the number of digits to use, see [print.default](#).

diag, upper, justify, right      optional arguments specifying how the triangular dissimilarity matrix is printed; see [print.dist](#).

...              potential further arguments (require by generic).

**See Also**

[daisy](#), [dissimilarity.object](#), [print](#), [print.default](#), [print.dist](#).

**Examples**

```
See example(daisy)

sd <- summary(daisy(matrix(rnorm(100), 20,5)))
sd # -> print.summary.dissimilarity(.)
str(sd)
```

---

print.fanny

---

*Print and Summary Methods for FANNY Objects*

---

**Description**

Prints the objective function, membership coefficients and clustering vector of fanny object.

This is a method for the function [print\(\)](#) for objects inheriting from class [fanny](#).

**Usage**

```
S3 method for class 'fanny'
print(x, digits = getOption("digits"), ...)
S3 method for class 'fanny'
summary(object, ...)
S3 method for class 'summary.fanny'
print(x, digits = getOption("digits"), ...)
```

**Arguments**

x, object      a [fanny](#) object.

digits          number of significant digits for printing, see [print.default](#).

...              potential further arguments (required by generic).

**See Also**

[fanny](#), [fanny.object](#), [print](#), [print.default](#).

---

`print.mona`*Print Method for MONA Objects*

---

**Description**

Prints the ordering of objects, separation steps, and used variables of a mona object.

This is a method for the function `print()` for objects inheriting from class `mona`.

**Usage**

```
S3 method for class 'mona'
print(x, ...)
```

**Arguments**

|                  |                                                   |
|------------------|---------------------------------------------------|
| <code>x</code>   | a mona object.                                    |
| <code>...</code> | potential further arguments (require by generic). |

**See Also**

`mona`, `mona.object`, `print`, `print.default`.

---

`print.pam`*Print Method for PAM Objects*

---

**Description**

Prints the medoids, clustering vector and objective function of pam object.

This is a method for the function `print()` for objects inheriting from class `pam`.

**Usage**

```
S3 method for class 'pam'
print(x, ...)
```

**Arguments**

|                  |                                                   |
|------------------|---------------------------------------------------|
| <code>x</code>   | a pam object.                                     |
| <code>...</code> | potential further arguments (require by generic). |

**See Also**

`pam`, `pam.object`, `print`, `print.default`.

---

 ruspini

*Ruspini Data*

---

### Description

The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering techniques.

### Usage

```
data(ruspini)
```

### Format

A data frame with 75 observations on 2 variables giving the x and y coordinates of the points, respectively.

### Source

E. H. Ruspini (1970) Numerical methods for fuzzy clustering. *Inform. Sci.* **2**, 319–350.

### References

see those in [agnes](#).

### Examples

```
data(ruspini)

Plot similar to Figure 4 in Stryuf et al (1996)
Not run: plot(pam(ruspini, 4), ask = TRUE)

Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

---

 silhouette

*Compute or Extract Silhouette Information from Clustering*

---

### Description

Compute silhouette information according to a given clustering in  $k$  clusters.

**Usage**

```

silhouette(x, ...)
Default S3 method:
 silhouette(x, dist, dmatrix, ...)
S3 method for class 'partition'
silhouette(x, ...)
S3 method for class 'clara'
silhouette(x, full = FALSE, subset = NULL, ...)

sortSilhouette(object, ...)
S3 method for class 'silhouette'
summary(object, FUN = mean, ...)
S3 method for class 'silhouette'
plot(x, nmax.lab = 40, max.strlen = 5,
 main = NULL, sub = NULL, xlab = expression("Silhouette width " * s[i]),
 col = "gray", do.col.sort = length(col) > 1, border = 0,
 cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)

```

**Arguments**

|                                     |                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                      | an object of appropriate class; for the default method an integer vector with $k$ different integer cluster codes or a list with such an <code>x\$clustering</code> component. Note that silhouette statistics are only defined if $2 \leq k \leq n - 1$ .                                                                                                                                  |
| <code>dist</code>                   | a dissimilarity object inheriting from class <code>dist</code> or coercible to one. If not specified, <code>dmatrix</code> must be.                                                                                                                                                                                                                                                         |
| <code>dmatrix</code>                | a symmetric dissimilarity matrix ( $n \times n$ ), specified instead of <code>dist</code> , which can be more efficient.                                                                                                                                                                                                                                                                    |
| <code>full</code>                   | logical or number in $[0, 1]$ specifying if a <i>full</i> silhouette should be computed for <code>clara</code> object. When a number, say $f$ , for a random <code>sample.int(n, size = f*n)</code> of the data the silhouette values are computed. This requires $O((f * n)^2)$ memory, since the full dissimilarity of the (sub)sample (see <a href="#">daisy</a> ) is needed internally. |
| <code>subset</code>                 | a subset from $1:n$ , specified instead of <code>full</code> to specify the indices of the observations to be used for the silhouette computations.                                                                                                                                                                                                                                         |
| <code>object</code>                 | an object of class <code>silhouette</code> .                                                                                                                                                                                                                                                                                                                                                |
| <code>...</code>                    | further arguments passed to and from methods.                                                                                                                                                                                                                                                                                                                                               |
| <code>FUN</code>                    | function used to summarize silhouette widths.                                                                                                                                                                                                                                                                                                                                               |
| <code>nmax.lab</code>               | integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.                                                                                                                                                                                                                                                                         |
| <code>max.strlen</code>             | positive integer giving the length to which strings are truncated in silhouette plot labeling.                                                                                                                                                                                                                                                                                              |
| <code>main, sub, xlab</code>        | arguments to <a href="#">title</a> ; have a sensible non-NULL default here.                                                                                                                                                                                                                                                                                                                 |
| <code>col, border, cex.names</code> | arguments passed <code>barplot()</code> ; note that the default used to be <code>col = heat.colors(n)</code> , <code>border = par("fg")</code> instead. <code>col</code> can also be a color vector of length $k$ for clusterwise coloring, see also <code>do.col.sort</code> :                                                                                                             |
| <code>do.col.sort</code>            | logical indicating if the colors <code>col</code> should be sorted “along” the silhouette; this is useful for casewise or clusterwise coloring.                                                                                                                                                                                                                                             |

do.n.k            logical indicating if  $n$  and  $k$  “title text” should be written.  
do.clus.stat      logical indicating if cluster size and averages should be written right to the silhouettes.

## Details

For each observation  $i$ , the *silhouette width*  $s(i)$  is defined as follows:

Put  $a(i)$  = average dissimilarity between  $i$  and all other points of the cluster to which  $i$  belongs (if  $i$  is the *only* observation in its cluster,  $s(i) := 0$  without further calculations). For all *other* clusters  $C$ , put  $d(i, C)$  = average dissimilarity of  $i$  to all observations of  $C$ . The smallest of these  $d(i, C)$  is  $b(i) := \min_C d(i, C)$ , and can be seen as the dissimilarity between  $i$  and its “neighbor” cluster, i.e., the nearest one to which it does *not* belong. Finally,

$$s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}.$$

`silhouette.default()` is now based on C code donated by Romain Francois (the R version being still available as `cluster::silhouetteR`).

Observations with a large  $s(i)$  (almost 1) are very well clustered, a small  $s(i)$  (around 0) means that the observation lies between two clusters, and observations with a negative  $s(i)$  are probably placed in the wrong cluster.

## Value

`silhouette()` returns an object, `sil`, of class `silhouette` which is an  $n \times 3$  matrix with attributes. For each observation  $i$ , `sil[i,]` contains the cluster to which  $i$  belongs as well as the neighbor cluster of  $i$  (the cluster, not containing  $i$ , for which the average dissimilarity between its observations and  $i$  is minimal), and the silhouette width  $s(i)$  of the observation. The `colnames` correspondingly are `c("cluster", "neighbor", "sil_width")`.

`summary(sil)` returns an object of class `summary.silhouette`, a list with components

`si.summary`: numerical `summary` of the individual silhouette widths  $s(i)$ .

`clus.avg.widths`: numeric (rank 1) array of clusterwise *means* of silhouette widths where `mean = FUN` is used.

`avg.width`: the total mean `FUN(s)` where  $s$  are the individual silhouette widths.

`clus.sizes`: `table` of the  $k$  cluster sizes.

`call`: if available, the `call` creating `sil`.

`Ordered`: logical identical to `attr(sil, "Ordered")`, see below.

`sortSilhouette(sil)` orders the rows of `sil` as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width  $s(i)$ .

`attr(sil, "Ordered")` is a logical indicating if `sil` is ordered as by `sortSilhouette()`. In that case, `rownames(sil)` will contain case labels or numbers, and `attr(sil, "iOrd")` the ordering index vector.

## Note

While `silhouette()` is *intrinsic* to the `partition` clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from `silhouette.default()` with `cutree()` and distance as input.

By default, for `clara()` partitions, the silhouette is just for the best random *subset* used. Use `full = TRUE` to compute (and later possibly plot) the full silhouette.

## Examples

```
data(ruspini)
pr4 <- pam(ruspini, 4)
str(si <- silhouette(pr4))
(ssi <- summary(si))
plot(si) # silhouette plot
plot(si, col = c("red", "green", "blue", "purple"))# with cluster-wise coloring

si2 <- silhouette(pr4$clustering, dist(ruspini, "canberra"))
summary(si2) # has small values: "canberra"'s fault
plot(si2, nmax= 80, cex.names=0.6)

op <- par(mfrow= c(3,2), oma= c(0,0, 3, 0),
 mgp= c(1.6,.8,0), mar= .1+c(4,2,2,2))
for(k in 2:6)
 plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE)
mtext("PAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
 outer = TRUE, font = par("font.main"), cex = par("cex.main")); frame()

the same with cluster-wise colours:
c6 <- c("tomato", "forest green", "dark blue", "purple2", "goldenrod4", "gray20")
for(k in 2:6)
 plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE,
 col = c6[1:k])
par(op)

clara(): standard silhouette is just for the best random subset
data(xclara)
set.seed(7)
str(xc1k <- xclara[sample(nrow(xclara), size = 1000) ,]) # rownames == indices
cl3 <- clara(xc1k, 3)
plot(silhouette(cl3))# only of the "best" subset of 46
The full silhouette: internally needs large (36 MB) dist object:
sf <- silhouette(cl3, full = TRUE) ## this is the same as
s.full <- silhouette(cl3$clustering, daisy(xc1k))
stopifnot(all.equal(sf, s.full, check.attributes = FALSE, tolerance = 0))
color dependent on original "3 groups of each 1000": % __FIXME ??__
plot(sf, col = 2+ as.integer(names(cl3$clustering)) %/% 1000,
 main ="plot(silhouette(clara(.), full = TRUE))")

Silhouette for a hierarchical clustering:
ar <- agnes(ruspini)
si3 <- silhouette(cutree(ar, k = 5), # k = 4 gave the same as pam() above
 daisy(ruspini))
stopifnot(is.data.frame(di3 <- as.data.frame(si3)))
plot(si3, nmax = 80, cex.names = 0.5)
```

```
2 groups: Agnes() wasn't too good:
si4 <- silhouette(cutree(ar, k = 2), daisy(ruspini))
plot(si4, nmax = 80, cex.names = 0.5)
```

sizeDiss

*Sample Size of Dissimilarity Like Object*

### Description

Returns the number of observations (*sample size*) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of  $f(n) = n(n - 1)/2$ .

### Usage

```
sizeDiss(d)
```

### Arguments

**d** any R object with length (typically)  $n(n - 1)/2$ .

### Value

a number;  $n$  if `length(d) == n(n-1)/2`, NA otherwise.

### See Also

[dissimilarity.object](#) and also [as.dist](#) for class dissimilarity and dist objects which have a Size attribute.

### Examples

```
sizeDiss(1:10)# 5, since 10 == 5 * (5 - 1) / 2
sizeDiss(1:9) # NA

n <- 1:100
stopifnot(n == sapply(n*(n-1)/2, function(n) sizeDiss(logical(n))))
```

summary.agnes

*Summary Method for 'agnes' Objects*

### Description

Returns (and prints) a summary list for an agnes object. Printing gives more output than the corresponding [print.agnes](#) method.

### Usage

```
S3 method for class 'agnes'
summary(object, ...)
S3 method for class 'summary.agnes'
print(x, ...)
```

### Arguments

x, object            a [agnes](#) object.  
...                  potential further arguments (require by generic).

### See Also

[agnes](#), [agnes.object](#).

### Examples

```
data(agriculture)
summary(agnes(agriculture))
```

---

### Description

Returns (and prints) a summary list for a clara object. Printing gives more output than the corresponding [print.clara](#) method.

### Usage

```
S3 method for class 'clara'
summary(object, ...)
S3 method for class 'summary.clara'
print(x, ...)
```

### Arguments

x, object            a [clara](#) object.  
...                  potential further arguments (require by generic).

### See Also

[clara.object](#)

## Examples

```
generate 2000 objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(400, 0,4), rnorm(400, 0,4)),
 cbind(rnorm(400,10,8), rnorm(400,40,6)),
 cbind(rnorm(400,30,4), rnorm(400, 0,4)),
 cbind(rnorm(400,40,4), rnorm(400,20,2)),
 cbind(rnorm(400,50,4), rnorm(400,50,4))
)
clx5 <- clara(x, 5)
Mis'classification' table:
table(rep(1:5, rep(400,5)), clx5$clustering) # -> 1 "error"
summary(clx5)

Graphically:
par(mfrow = c(3,1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0,0,2,0))
plot(x, col = rep(2:6, rep(400,5)))
plot(clx5)
```

---

summary.diana

---

Summary Method for 'diana' Objects

---

## Description

Returns (and prints) a summary list for a diana object.

## Usage

```
S3 method for class 'diana'
summary(object, ...)
S3 method for class 'summary.diana'
print(x, ...)
```

## Arguments

x, object            a [diana](#) object.

...                  potential further arguments (require by generic).

## See Also

[diana](#), [diana.object](#).

---

summary.mona*Summary Method for 'mona' Objects*

---

**Description**

Returns (and prints) a summary list for a mona object.

**Usage**

```
S3 method for class 'mona'
summary(object, ...)
S3 method for class 'summary.mona'
print(x, ...)
```

**Arguments**

x, object            a [mona](#) object.  
...                  potential further arguments (require by generic).

**See Also**

[mona](#), [mona.object](#).

---

summary.pam*Summary Method for PAM Objects*

---

**Description**

Summarize a [pam](#) object and return an object of class `summary.pam`. There's a [print](#) method for the latter.

**Usage**

```
S3 method for class 'pam'
summary(object, ...)
S3 method for class 'summary.pam'
print(x, ...)
```

**Arguments**

x, object            a [pam](#) object.  
...                  potential further arguments (require by generic).

**See Also**

[pam](#), [pam.object](#).

---

|              |                                       |
|--------------|---------------------------------------|
| twins.object | <i>Hierarchical Clustering Object</i> |
|--------------|---------------------------------------|

---

### Description

The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

### Value

See [agnes.object](#) and [diana.object](#) for details.

### GENERATION

This class of objects is returned from `agnes` or `diana`.

### METHODS

The "twins" class has a method for the following generic function: `pltree`.

### INHERITANCE

The following classes inherit from class "twins": "agnes" and "diana".

### See Also

[agnes,diana](#).

---

|                  |                                             |
|------------------|---------------------------------------------|
| volume.ellipsoid | <i>Compute the Volume (of an Ellipsoid)</i> |
|------------------|---------------------------------------------|

---

### Description

Compute the volume of geometric R object. This is a generic function and has a method for ellipsoid objects (typically resulting from `ellipsoidhull()`).

### Usage

```
volume(object, ...)
S3 method for class 'ellipsoid'
volume(object, log = FALSE, ...)
```

### Arguments

|        |                                                                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an R object the volume of which is wanted; for the <code>ellipsoid</code> method, an object of that class (see <a href="#">ellipsoidhull</a> or the example below). |
| log    | <a href="#">logical</a> indicating if the volume should be returned in log scale. Maybe needed in largish dimensions.                                               |
| ...    | potential further arguments of methods, e.g. <code>log</code> .                                                                                                     |

**Value**

a number, the volume  $V$  (or  $\log(V)$  if `log = TRUE`) of the given object.

**Author(s)**

Martin Maechler (2002, extracting from former [clusplot](#) code); Keefe Murphy (2019) provided code for dimensions  $d > 2$ .

**See Also**

[ellipsoidhull](#) for spanning ellipsoid computation.

**Examples**

```
example(ellipsoidhull) # which defines 'ellipsoid' object <namefoo>

myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10),
 class = "ellipsoid")
volume(myEl)# i.e. "area" here (d = 2)
myEl # also mentions the "volume"

set.seed(1)
d5 <- matrix(rt(500, df=3), 100,5)
e5 <- ellipsoidhull(d5)
```

---

votes.repub

---

*Votes for Republican Candidate in Presidential Elections*

---

**Description**

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

**Usage**

```
data(votes.repub)
```

**Source**

S. Peterson (1973): *A Statistical History of the American Presidential Elections*. New York: Frederick Ungar Publishing Co.

Data from 1964 to 1976 is from R. M. Scammon, *American Votes 12*, Congressional Quarterly.

xclara

*Bivariate Data Set with 3 Clusters***Description**

An artificial data set consisting of 3000 points in 3 quite well-separated clusters.

**Usage**

```
data(xclara)
```

**Format**

A data frame with 3000 observations on 2 numeric variables (named V1 and V2) giving the  $x$  and  $y$  coordinates of the points, respectively.

**Note**

Our version of the xclara is slightly more rounded than the one from `read.table("xclara.dat")` and the relative difference measured by `all.equal` is  $1.15\text{e-}7$  for V1 and  $1.17\text{e-}7$  for V2 which suggests that our version has been the result of a `options(digits = 7)` formatting.

Previously (before May 2017), it was claimed the three cluster were each of size 1000, which is clearly wrong. `pam(*, 3)` gives cluster sizes of 899, 1149, and 952, which apart from seven “outliers” (or “mislabellings”) correspond to observation indices {1 : 900}, {901 : 2050}, and {2051 : 3000}, see the example.

**Source**

Sample data set accompanying the reference below (file ‘xclara.dat’ in side ‘clus\_examples.tar.gz’).

**References**

Anja Struyf, Mia Hubert & Peter J. Rousseeuw (1996) Clustering in an Object-Oriented Environment. *Journal of Statistical Software* **1**. doi:10.18637/jss.v001.i04

**Examples**

```
Visualization: Assuming groups are defined as {1:1000}, {1001:2000}, {2001:3000}
plot(xclara, cex = 3/4, col = rep(1:3, each=1000))
p.ID <- c(78, 1411, 2535) ## PAM's medoid indices == pam(xclara, 3)$id.med
text(xclara[p.ID,], labels = 1:3, cex=2, col=1:3)

px <- pam(xclara, 3) ## takes ~2 seconds
cxcl <- px$clustering ; iCl <- split(seq_along(cxcl), cxcl)
boxplot(iCl, range = 0.7, horizontal=TRUE,
 main = "Indices of the 3 clusters of pam(xclara, 3)")

Look more closely now:
bxCl <- boxplot(iCl, range = 0.7, plot=FALSE)
We see 3 + 2 + 2 = 7 clear "outlier"s or "wrong group" observations:
with(bxCl, rbind(out, group))
out 1038 1451 1610 30 327 562 770
```

```
group 1 1 1 2 2 3 3
Apart from these, what are the robust ranges of indices? -- Robust range:
t(iR <- bxC1$stats[c(1,5),])
1 900
901 2050
2051 3000
gc <- adjustcolor("gray20",1/2)
abline(v = iR, col = gc, lty=3)
axis(3, at = c(0, iR[2,]), padj = 1.2, col=gc, col.axis=gc)
```

## Chapter 21

# The codetools package

---

checkUsage

*Check R Code for Possible Problems*

---

### Description

Check R code for possible problems.

### Usage

```
checkUsage(fun, name = "<anonymous>", report = cat, all = FALSE,
 suppressLocal = FALSE, suppressParamAssigns = !all,
 suppressParamUnused = !all, suppressFundefMismatch = FALSE,
 suppressLocalUnused = FALSE, suppressNoLocalFun = !all,
 skipWith = FALSE, suppressUndefined = dfltSuppressUndefined,
 suppressPartialMatchArgs = TRUE)
checkUsageEnv(env, ...)
checkUsagePackage(pack, ...)
```

### Arguments

|                      |                                                           |
|----------------------|-----------------------------------------------------------|
| fun                  | closure.                                                  |
| name                 | character; name of closure.                               |
| env                  | environment containing closures to check.                 |
| pack                 | character naming package to check.                        |
| ...                  | options to be passed to checkUsage.                       |
| report               | function to use to report possible problems.              |
| all                  | logical; report all possible problems if TRUE.            |
| suppressLocal        | suppress all local variable warnings.                     |
| suppressParamAssigns | suppress warnings about assignments to formal parameters. |
| suppressParamUnused  | suppress warnings about unused formal parameters.         |

```

suppressFundefMismatch
 suppress warnings about multiple local function definitions with different formal
 argument lists
suppressLocalUnused
 suppress warnings about unused local variables
suppressNoLocalFun
 suppress warnings about using local variables as functions with no apparent
 local function definition
skipWith
 logical; if true, do not examine code portion of with or within expressions.
suppressUndefined
 suppress warnings about undefined global functions and variables.
suppressPartialMatchArgs
 suppress warnings about partial argument matching

```

### Details

checkUsage checks a single R closure. Options control which possible problems to report. The default settings are moderately verbose. A first pass might use suppressLocal=TRUE to suppress all information related to local variable usage. The suppressXYZ values can either be scalar logicals or character vectors; then they are character vectors they only suppress problem reports for the variables with names in the vector.

checkUsageEnv and checkUsagePackage are convenience functions that apply checkUsage to all closures in an environment or a package. checkUsagePackage requires that the package be loaded. If the package has a name space then the internal name space frame is checked.

### Author(s)

Luke Tierney

### Examples

```

checkUsage(checkUsage)
checkUsagePackage("codetools", all=TRUE)
Not run: checkUsagePackage("base", suppressLocal=TRUE)

```

---

codetools

*Low Level Code Analysis Tools for R*

---

### Description

These functions provide some tools for analysing R code. Mainly intended to support the other tools in this package and byte code compilation.

### Usage

```

collectLocals(e, collect)
collectUsage(fun, name = "<anonymous>", ...)
constantFold(e, env = NULL, fail = NULL)
findFuncLocals(formals, body)
findLocals(e, envir = .BaseEnv)
findLocalsList(elist, envir = .BaseEnv)

```

```
flattenAssignment(e)
getAssignedVar(e)
isConstantValue(v, w)
makeCodeWalker(..., handler, call, leaf)
makeConstantFolder(..., leaf, handler, call, exit, isLocal, foldable,
 isConstant, signal)
makeLocalsCollector(..., leaf, handler, isLocal, exit, collect)
makeUsageCollector(fun, ..., name, enterLocal, enterGlobal, enterInternal,
 startCollectLocals, finishCollectLocals, warn,
 signal)
walkCode(e, w = makeCodeWalker())
```

### Arguments

|                     |                                 |
|---------------------|---------------------------------|
| e                   | R expression.                   |
| elist               | list of R expressions.          |
| v                   | R object.                       |
| fun                 | closure.                        |
| formals             | formal arguments of a closure.  |
| body                | body of a closure.              |
| name                | character.                      |
| env                 | character.                      |
| envir               | environment.                    |
| w                   | code walker.                    |
| ...                 | extra elements for code walker. |
| collect             | function.                       |
| fail                | function.                       |
| handler             | function.                       |
| call                | function.                       |
| leaf                | function.                       |
| isLocal             | function.                       |
| exit                | function.                       |
| enterLocal          | function.                       |
| enterGlobal         | function.                       |
| enterInternal       | function.                       |
| startCollectLocals  | function.                       |
| finishCollectLocals | function.                       |
| warn                | function.                       |
| signal              | function.                       |
| isConstant          | function.                       |
| foldable            | function.                       |

---

`findGlobals`*Find Global Functions and Variables Used by a Closure*

---

**Description**

Finds global functions and variables used by a closure.

**Usage**

```
findGlobals(fun, merge = TRUE)
```

**Arguments**

|                    |                                     |
|--------------------|-------------------------------------|
| <code>fun</code>   | function object; usually a closure. |
| <code>merge</code> | logical                             |

**Details**

The result is an approximation. R semantics only allow variables that might be local to be identified (and event that assumes no use of `assign` and `rm`).

**Value**

Character vector if `merge` is true; otherwise, a list with functions and variables character vector components. Character vectors are of length zero For non-closures.

**Author(s)**

Luke Tierney

**Examples**

```
findGlobals(findGlobals)
findGlobals(findGlobals, merge = FALSE)
```

---

`showTree`*Print Lisp-Style Representation of R Expression*

---

**Description**

Prints a Lisp-style representation of R expression. This can be useful for understanding how some things are parsed.

**Usage**

```
showTree(e, write = cat)
```

**Arguments**

|                    |                                               |
|--------------------|-----------------------------------------------|
| <code>e</code>     | R expression.                                 |
| <code>write</code> | function of one argument to write the result. |

**Author(s)**

Luke Tierney

**Examples**

```
showTree(quote(-3))
showTree(quote("x"<-1))
showTree(quote("f"(x)))
```

2770

*showTree*

## Chapter 22

# The foreign package

---

lookup.xport

*Lookup Information on a SAS XPORT Format Library*

---

### Description

Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

### Usage

```
lookup.xport(file)
```

### Arguments

|      |                                                                                             |
|------|---------------------------------------------------------------------------------------------|
| file | character variable with the name of the file to read. The file must be in SAS XPORT format. |
|------|---------------------------------------------------------------------------------------------|

### Value

A list with one component for each dataset in the XPORT format library.

### Author(s)

Saikat DebRoy

### References

SAS Technical Support document TS-140: “The Record Layout of a Data Set in SAS Transport (XPORT) Format” available as <https://support.sas.com/content/dam/SAS/support/en/technical-papers/record-layout-of-a-sas-version-5-or-6-data-set-in-sas-transport-xport-format.pdf>

[read.xport](#)

**Examples**

```
Not run: ## no XPORT file is installed.
lookup.xport("test.xpt")

End(Not run)
```

read.arff

*Read Data from ARFF Files***Description**

Reads data from Weka Attribute-Relation File Format (ARFF) files.

**Usage**

```
read.arff(file)
```

**Arguments**

|      |                                                                                                                                                                                      |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | a character string with the name of the ARFF file to read from, or a <a href="#">connection</a> which will be opened if necessary, and if so closed at the end of the function call. |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Value**

A data frame containing the data from the ARFF file.

**References**

Attribute-Relation File Format [https://waikato.github.io/weka-wiki/formats\\_and\\_processing/arff/](https://waikato.github.io/weka-wiki/formats_and_processing/arff/).

**See Also**

[write.arff](#); functions `write.arff` and `read.arff` in package **RWeka** which provide some support for logicals via conversion to or from factors.

read.dbf

*Read a DBF File***Description**

The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

The DBF format is documented but not much adhered to. There is no guarantee this will read all DBF files.

**Usage**

```
read.dbf(file, as.is = FALSE)
```

## Arguments

|       |                                                       |
|-------|-------------------------------------------------------|
| file  | name of input file                                    |
| as.is | should character vectors not be converted to factors? |

## Details

DBF is the extension used for files written for the 'XBASE' family of database languages, 'covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products' (<https://www.clicketyclick.dk/databases/xbase/format/>). Most of these follow the file structure used by Ashton-Tate's dBase II, III or 4 (later owned by Borland).

read.dbf is based on C code from <http://shapelib.maptools.org/> which implements the 'XBASE' specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates): all other field types are read as-is as character vectors. A numeric field is read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

## Value

A data frame of data from the DBF file; note that the field names are adjusted to use in R using `make.names(unique=TRUE)`.

There is an attribute "data\_type" giving the single-character dBase types for each field.

## Note

Not to be able to read a particular 'DBF' file is not a bug: this is a convenience function especially for shapefiles.

## Author(s)

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

## References

<http://shapelib.maptools.org/>.

[write.dbf](#)

## Examples

```
x <- read.dbf(system.file("files/sids.dbf", package="foreign"))[1:]
str(x)
summary(x)
```

read.dta

*Read Stata Binary Files***Description**

Reads a file in Stata version 5–12 binary format into a data frame.

Frozen: will not support Stata formats after 12.

**Usage**

```
read.dta(file, convert.dates = TRUE, convert.factors = TRUE,
 missing.type = FALSE,
 convert.underscore = FALSE, warn.missing.labels = TRUE)
```

**Arguments**

|                     |                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------|
| file                | a filename or URL as a character string.                                                              |
| convert.dates       | Convert Stata dates to Date class, and date-times to POSIXct class?                                   |
| convert.factors     | Use Stata value labels to create factors? (Version 6.0 or later).                                     |
| missing.type        | For version 8 or later, store information about different types of missing data?                      |
| convert.underscore  | Convert "_" in Stata variable names to "." in R names?                                                |
| warn.missing.labels | Warn if a variable is specified with value labels and those value labels are not present in the file. |

**Details**

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is only supported on some platforms.)

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, timestamp, and variable/dataset characteristics are stored as attributes of the data frame.

By default Stata dates (%d and %td formats) are converted to R's Date class, and variables with Stata value labels are converted to factors. Ordinarily, read.dta will not convert a variable to a factor unless a label is present for every level. Use convert.factors = NA to override this. In any case the value label and format information is stored as attributes on the returned data frame. Stata's date formats are sketchily documented: if necessary use convert.dates = FALSE and examine the attributes to work out how to post-process the dates.

Stata 8 introduced a system of 27 different missing data values. If missing.type is TRUE a separate list is created with the same variable names as the loaded data. For string variables the list value is NULL. For other variables the value is NA where the observation is not missing and 0–26 when the observation is missing. This is attached as the "missing" attribute of the returned value.

The default file format for Stata 13, format-115, is substantially different from those for Stata 5–12.

**Value**

A data frame with attributes. These will include "datalabel", "time.stamp", "formats", "types", "val.labels", "var.labels" and "version" and may include "label.table" and "expansion.table". Possible versions are 5, 6, 7, -7 (Stata 7SE, 'format-111'), 8 (Stata 8 and 9, 'format-113'), 10 (Stata 10 and 11, 'format-114'). and 12 (Stata 12, 'format-115').

The value labels in attribute "val.labels" name a table for each variable, or are an empty string. The tables are elements of the named list attribute "label.table": each is an integer vector with names.

**Author(s)**

Thomas Lumley and R-core members: support for value labels by Brian Quistorff.

Different approaches are available in package **memisc** (see its help for Stata.file), function read\_dta in package **haven** and package **readstata13**.

[write.dta](#), [attributes](#), [Date](#), [factor](#)

**Examples**

```
write.dta(swiss,swissfile <- tempfile())
read.dta(swissfile)
```

---

read.epiinfo

---

*Read Epi Info Data Files*

---

**Description**

Reads data files in the .REC format used by Epi Info versions 6 and earlier and by EpiData. Epi Info is a public domain database and statistics package produced by the US Centers for Disease Control and EpiData is a freely available data entry and validation system.

**Usage**

```
read.epiinfo(file, read.deleted = FALSE, guess.broken.dates = FALSE,
 thisyear = NULL, lower.case.names = FALSE)
```

**Arguments**

|                                 |                                                                               |
|---------------------------------|-------------------------------------------------------------------------------|
| <code>file</code>               | A filename, URL, or connection.                                               |
| <code>read.deleted</code>       | Deleted records are read if TRUE, omitted if FALSE or replaced with NA if NA. |
| <code>guess.broken.dates</code> | Attempt to convert dates with 0 or 2 digit year information (see 'Details').  |
| <code>thisyear</code>           | A 4-digit year to use for dates with no year. Defaults to the current year.   |
| <code>lower.case.names</code>   | Convert variable names to lowercase?                                          |

**Details**

Epi Info allows dates to be specified with no year or with a 2 or 4 digits. Dates with four-digit years are always converted to Date class. With the `guess.broken.dates` option the function will attempt to convert two-digit years using the operating system's default method (see [Date](#)) and will use the current year or the `thisyear` argument for dates with no year information.

If `read.deleted` is TRUE the "deleted" attribute of the data frame indicates the deleted records.

**Value**

A data frame.

**Note**

Some later versions of Epi Info use the Microsoft Access file format to store data. That may be readable with the **RODBC** package.

read.epiinfo("oswego.rec", guess.broken.dates = TRUE, thisyear = "1972")

End(Not run)
```

---

read.mtp

*Read a Minitab Portable Worksheet*

---

**Description**

Return a list with the data stored in a file as a Minitab Portable Worksheet.

**Usage**

```
read.mtp(file)
```

**Arguments**

file                      character variable with the name of the file to read. The file must be in Minitab Portable Worksheet format.

**Value**

A list with one component for each column, matrix, or constant stored in the Minitab worksheet.

**Note**

This function was written around 1990 for the format current then. Later versions of Minitab appear to have added to the format.

**Author(s)**

Douglas M. Bates

**References**

<https://www.minitab.com/>

**Examples**

```
Not run:
read.mtp("ex1-10.mtp")

End(Not run)
```

---

read.octave

*Read Octave Text Data Files*

---

**Description**

Read a file in Octave text data format into a list.

**Usage**

```
read.octave(file)
```

**Arguments**

file                      a character string with the name of the file to read.

**Details**

This function is used to read in files in Octave text data format, as created by `save -text` in Octave. It knows about most of the common types of variables, including the standard atomic (real and complex scalars, matrices, and  $N$ -d arrays, strings, ranges, and boolean scalars and matrices) and recursive (structs, cells, and lists) ones, but has no guarantee to read all types. If a type is not recognized, a warning indicating the unknown type is issued, it is attempted to skip the unknown entry, and NULL is used as its value. Note that this will give incorrect results, and maybe even errors, in the case of unknown recursive data types.

As Octave can read MATLAB binary files, one can make the contents of such files available to R by using Octave's load and save (as text) facilities as an intermediary step.

**Value**

A list with one named component for each variable in the file.

**Author(s)**

Stephen Eglen <stephen@gnu.org> and Kurt Hornik

**References**

---

read.spss

*Read an SPSS Data File*

---

**Description**

read.spss reads a file stored by the SPSS save or export commands.

This was originally written in 2000 and has limited support for changes in SPSS formats since (which have not been many).

**Usage**

```
read.spss(file, use.value.labels = TRUE, to.data.frame = FALSE,
 max.value.labels = Inf, trim.factor.names = FALSE,
 trim_values = TRUE, reencode = NA, use.missings = to.data.frame,
 sub = ".", add.undeclared.levels = c("sort", "append", "no"),
 duplicated.value.labels = c("append", "condense"),
 duplicated.value.labels.infix = "_duplicated_", ...)
```

**Arguments**

|                   |                                                                                                                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file              | character string: the name of the file or URL to read.                                                                                                                                                                     |
| use.value.labels  | logical: convert variables with value labels into R factors with those levels? This is only done if there are at least as many labels as values of the variable (when values without a matching label are returned as NA). |
| to.data.frame     | logical: return a data frame?                                                                                                                                                                                              |
| max.value.labels  | logical: only variables with value labels and at most this many unique values will be converted to factors if TRUE.                                                                                                        |
| trim.factor.names | logical: trim trailing spaces from factor levels?                                                                                                                                                                          |
| trim_values       | logical: should values and value labels have trailing spaces ignored when matching for use.value.labels = TRUE?                                                                                                            |
| reencode          | logical: should character strings be re-encoded to the current locale. The default, NA, means to do so in UTF-8 or latin-1 locales, only. Alternatively a character string specifying an encoding to assume for the file.  |
| use.missings      | logical: should information on user-defined missing values be used to set the corresponding values to NA?                                                                                                                  |

sub character string: If not NA it is used by `iconv` to replace any non-convertible bytes in character/factor input. Default is `".."`. For back compatibility with **foreign** versions `<= 0.8-68` use `sub=NA`.

add.undeclared.levels character: specify how to handle variables with at least one value label and further non-missing values that have no value label (like a factor levels in R). For `"sort"` (the default) it adds undeclared factor levels to the already declared levels (and labels) and sort them according to level, for `"append"` it appends undeclared factor levels to declared levels (and labels) without sorting, and for `"no"` this does not convert to factor in case of numeric SPSS levels (not labels), and still converts to factor if the SPSS levels are characters and `to.data.frame=TRUE`. For back compatibility with **foreign** versions `<= 0.8-68` use `add.undeclared.levels="no"` (not recommended as this may convert some values with missing corresponding value labels to NA).

duplicated.value.labels character: what to do with duplicated value labels for different levels. For `"append"` (the default), the first original value label is kept while further duplicated labels are renamed to `paste0(label, duplicated.value.labels.infix, level)`, for `"condense"`, all levels with identical labels are condensed into exactly the first of these levels in R. Back compatibility with **foreign** versions `<= 0.8-68` is not given as R versions `>= 3.4.0` no longer support duplicated factor labels.

duplicated.value.labels.infix character: the infix used for labels of factor levels with duplicated value labels in SPSS (default `"_duplicated_"`) if `duplicated.value.labels="append"`.

... passed to `as.data.frame` if `to.data.frame = TRUE`.

## Details

This uses modified code from the PSPP project (<http://www.gnu.org/software/pspp/> for reading the SPSS formats.

If the filename appears to be a URL (of schemes `'http:'`, `'ftp:'` or `'https:'`) the URL is first downloaded to a temporary file and then read. (`'https:'` is supported where supported by [download.file](#) with its current default method.)

Occasionally in SPSS, value labels will be added to some values of a continuous variable (e.g. to distinguish different types of missing data), and you will not want these variables converted to factors. By setting `max.value.labels` you can specify that variables with a large number of distinct values are not converted to factors even if they have value labels.

If SPSS variable labels are present, they are returned as the `"variable.labels"` attribute of the answer.

Fixed length strings (including value labels) are padded on the right with spaces by SPSS, and so are read that way by R. The default argument `trim_values=TRUE` causes trailing spaces to be ignored when matching to value labels, as examples have been seen where the strings and the value labels had different amounts of padding. See the examples for [sub](#) for ways to remove trailing spaces in character data.

URL <https://learn.microsoft.com/en-us/windows/win32/intl/code-page-identifiers> provides a list of translations from Windows codepage numbers to encoding names that `iconv` is likely to know about and so suitable values for `reencode`. Automatic re-encoding is attempted for apparent codepages of 200 or more in a UTF-8 or latin-1 locale: some other high-numbered codepages can be re-encoded on most systems, but the encoding names are platform-dependent (see [iconvlist](#)).

**Value**

A list (or optionally a data frame) with one component for each variable in the saved data set.

If what looks like a Windows codepage was recorded in the SPSS file, it is attached (as a number) as attribute "codepage" to the result.

There may be attributes "label.table" and "variable.labels". Attribute "label.table" is a named list of value labels with one element per variable, either NULL or a named character vector. Attribute "variable.labels" is a named character vector with names the short variable names and elements the long names.

If there are user-defined missing values, there will be a attribute "Missings". This is a named list with one list element per variable. Each element has an element type, a length-one character vector giving the type of missingness, and may also have an element value with the values corresponding to missingness. This is a complex subject (where the R and C source code for read.spss is the main documentation), but the simplest cases are types "one", "two" and "three" with a corresponding number of (real or string) values whose labels can be found from the "label.table" attribute. Other possibilities are a finite or semi-infinite range, possibly plus a single value. See also [http://www.gnu.org/software/pspp/manual/html\\_node/Missing-Observations.html#Missing-Observations](http://www.gnu.org/software/pspp/manual/html_node/Missing-Observations.html#Missing-Observations).

**Note**

If SPSS value labels are converted to factors the underlying numerical codes will not in general be the same as the SPSS numerical values, since the numerical codes in R are always 1, 2, 3, ...

You may see warnings about the file encoding for SPSS save files: it is possible such files contain non-ASCII character data which need re-encoding. The most common occurrence is Windows codepage 1252, a superset of Latin-1. The encoding is recorded (as an integer) in attribute "codepage" of the result if it looks like a Windows codepage. Automatic re-encoding is done only in UTF-8 and latin-1 locales: see argument `reencode`.

**Author(s)**

Saikat DebRoy and the R-core team

**See Also**

A different interface also based on the PSPP codebase is available in package **memisc**: see its help for `spss.system.file`.

**Examples**

```
(sav <- system.file("files", "electric.sav", package = "foreign"))
dat <- read.spss(file=sav)
str(dat) # list structure with attributes

dat <- read.spss(file=sav, to.data.frame=TRUE)
str(dat) # now a data.frame

Now we use an example file that is not very well structured and
hence may need some special treatment with appropriate argument settings.
Expect lots of warnings as value labels (corresponding to R factor labels) are uncomplete,
and an unsupported long string variable is present in the data
(sav <- system.file("files", "testdata.sav", package = "foreign"))
```

```

Examples for add.undeclared.levels:
add.undeclared.levels = "sort" (default):
x.sort <- read.spss(file=sav, to.data.frame = TRUE)
add.undeclared.levels = "append":
x.append <- read.spss(file=sav, to.data.frame = TRUE,
 add.undeclared.levels = "append")
add.undeclared.levels = "no":
x.no <- read.spss(file=sav, to.data.frame = TRUE,
 add.undeclared.levels = "no")

levels(x.sort$factor_n_undeclared)
levels(x.append$factor_n_undeclared)
str(x.no$factor_n_undeclared)

Examples for duplicated.value.labels:
duplicated.value.labels = "append" (default)
x.append <- read.spss(file=sav, to.data.frame=TRUE)
duplicated.value.labels = "condense"
x.condense <- read.spss(file=sav, to.data.frame=TRUE,
 duplicated.value.labels = "condense")

levels(x.append$factor_n_duplicated)
levels(x.condense$factor_n_duplicated)

as.numeric(x.append$factor_n_duplicated)
as.numeric(x.condense$factor_n_duplicated)

Long Strings (>255 chars) are imported in consecutive separate variables
(see warning about subtype 14):
x <- read.spss(file=sav, to.data.frame=TRUE, stringsAsFactors=FALSE)

cat.long.string <- function(x, w=70) cat(paste(strwrap(x, width=w), "\n"))

first part: x$string_500:
cat.long.string(x$string_500)
second part: x$STRIN0:
cat.long.string(x$STRIN0)
complete long string:
long.string <- apply(x[,c("string_500", "STRIN0")], 1, paste, collapse="")
cat.long.string(long.string)

```

---

read.ssd

---

*Obtain a Data Frame from a SAS Permanent Dataset, via read.xport*

---

## Description

Generates a SAS program to convert the ssd contents to SAS transport format and then uses read.xport to obtain a data frame.

## Usage

```

read.ssd(libname, sectionnames,
 tmpXport=tempfile(), tmpProgLoc=tempfile(), sascmd="sas")

```

## Arguments

|              |                                                                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| libname      | character string defining the SAS library (usually a directory reference)                                                                                                                                                            |
| sectionnames | character vector giving member names. These are files in the libname directory. They will usually have a .ssd0x or .sas7bdat extension, which should be omitted. Use of ASCII names of at most 8 characters is strongly recommended. |
| tmpXport     | character string: location where temporary xport format archive should reside – defaults to a randomly named file in the session temporary directory, which will be removed.                                                         |
| tmpProgLoc   | character string: location where temporary conversion SAS program should reside – defaults to a randomly named file in session temporary directory, which will be removed on successful operation.                                   |
| sascmd       | character string giving full path to SAS executable.                                                                                                                                                                                 |

## Details

Creates a SAS program and runs it.

Error handling is primitive.

## Value

A data frame if all goes well, or NULL with warnings and some enduring side effects (log file for auditing)

## Note

**This requires SAS to be available.** If you have a SAS dataset without access to SAS you will need another product to convert it to a format such as .csv, for example ‘Stat/Transfer’ or ‘DBMS/Copy’ or the ‘SAS System Viewer’ (Windows only).

SAS requires section names to be no more than 8 characters. This is worked by the use of symbolic links: these are barely supported on Windows.

## Author(s)

For Unix: VJ Carey <stvjc@channing.harvard.edu>

## See Also

## Examples

```
if there were some files on the web we could get a real
runnable example
Not run:
R> list.files("trialdata")
[1] "baseline.sas7bdat" "form11.sas7bdat" "form12.sas7bdat"
[4] "form13.sas7bdat" "form22.sas7bdat" "form23.sas7bdat"
[7] "form3.sas7bdat" "form4.sas7bdat" "form48.sas7bdat"
[10] "form50.sas7bdat" "form51.sas7bdat" "form71.sas7bdat"
[13] "form72.sas7bdat" "form8.sas7bdat" "form9.sas7bdat"
[16] "form90.sas7bdat" "form91.sas7bdat"
R> baseline <- read.ssd("trialdata", "baseline")
```

```
R> form90 <- read.ssd("trialdata", "form90")

Or for a Windows example
sashome <- "/Program Files/SAS/SAS 9.1"
read.ssd(file.path(sashome, "core", "sashelp"), "retail",
 sascmd = file.path(sashome, "sas.exe"))

End(Not run)
```

---

read.systat

---

*Obtain a Data Frame from a Systat File*

---

## Description

read.systat reads a rectangular data file stored by the Systat SAVE command as (legacy) \*.sys or more recently \*.syd files.

## Usage

```
read.systat(file, to.data.frame = TRUE)
```

## Arguments

file                    character variable with the name of the file to read  
to.data.frame    return a data frame (otherwise a list)

## Details

The function only reads those Systat files that are rectangular data files (mtype = 1), and warns when files have non-standard variable name codings. The files tested were produced on MS-DOS and Windows: files for the Mac version of Systat have a completely different format.

The C code was originally written for an add-on module for Systat described in Bivand (1992 paper). Variable names retain the trailing dollar in the list returned when to.data.frame is FALSE, and in that case character variables are returned as is and filled up to 12 characters with blanks on the right. The original function was limited to reading Systat files with up to 256 variables (a Systat limitation); it will now read up to 8192 variables.

If there is a user comment in the header this is returned as attribute "comment". Such comments are always a multiple of 72 characters (with a maximum of 720 chars returned), normally padded with trailing spaces.

## Value

A data frame (or list) with one component for each variable in the saved data set.

## Author(s)

Roger Bivand

## References

Systat Manual, 1987, 1989

Bivand, R. S. (1992) SYSTAT-compatible software for modelling spatial dependence among observations. *Computers and Geosciences* **18**, 951–963.

## Examples

```
summary(iris)
iris.s <- read.systat(system.file("files/Iris.syd", package="foreign")[1])
str(iris.s)
summary(iris.s)
```

---

read.xport

---

*Read a SAS XPORT Format Library*

---

## Description

Reads a file as a SAS XPORT format library and returns a list of data.frames.

## Usage

```
read.xport(file, ...)
```

## Arguments

|      |                                                                                             |
|------|---------------------------------------------------------------------------------------------|
| file | character variable with the name of the file to read. The file must be in SAS XPORT format. |
| ...  | passed to <a href="#">as.data.frame</a> when creating the data frames.                      |

## Value

If there is a more than one dataset in the XPORT format library, a named list of data frames, otherwise a data frame. The columns of the data frames will be either numeric (corresponding to numeric in SAS) or factor (corresponding to character in SAS). All SAS numeric missing values (including special missing values represented by .\_, .A to .Z by SAS) are mapped to R NA.

Trailing blanks are removed from character columns before conversion to a factor. Some sources claim that character missing values in SAS are represented by ' ' or ' ': these are not treated as R missing values.

```
Not run: ## no XPORT file is installed
read.xport("test.xpt")

End(Not run)
```

---

S3 read functions

*Read an S3 Binary or data.dump File*

---

**Description**

Reads binary data files or `data.dump` files that were produced in S version 3.

**Usage**

```
data.restore(file, print = FALSE, verbose = FALSE, env = .GlobalEnv)
read.S(file)
```

**Arguments**

|                      |                                                                   |
|----------------------|-------------------------------------------------------------------|
| <code>file</code>    | the filename of the S-PLUS <code>data.dump</code> or binary file. |
| <code>print</code>   | whether to print the name of each object as read from the file.   |
| <code>verbose</code> | whether to print the name of every subitem within each object.    |
| <code>env</code>     | environment within which to create the restored object(s).        |

**Details**

`read.S` can read the binary files produced in some older versions of S-PLUS on either Windows (versions 3.x, 4.x, 2000) or Unix (version 3.x with 4 byte integers). It automatically detects whether the file was produced on a big- or little-endian machine and adapts itself accordingly.

`data.restore` can read a similar range of files produced by `data.dump` and for newer versions of S-PLUS, those from `data.dump(..., oldStyle=TRUE)`.

Not all S3 objects can be handled in the current version. The most frequently encountered exceptions are functions and expressions; you will also have trouble with objects that contain model formulas. In particular, comments will be lost from function bodies, and the argument lists of functions will often be changed.

**Value**

For `read.S`, an R version of the S3 object.

For `data.restore`, the name of the file.

**Author(s)**

Duncan Murdoch

## Examples

```
if you have an S-PLUS _Data file containing 'myobj'
Not run: read.S(file.path("_Data", "myobj"))
data.restore("dumpdata", print = TRUE)

End(Not run)
```

---

write.arff

---

Write Data into ARFF Files

---

## Description

Writes data into Weka Attribute-Relation File Format (ARFF) files.

## Usage

```
write.arff(x, file, eol = "\n", relation = deparse(substitute(x)))
```

## Arguments

|          |                                                                                                                  |
|----------|------------------------------------------------------------------------------------------------------------------|
| x        | the data to be written, preferably a matrix or data frame. If not, coercion to a data frame is attempted.        |
| file     | either a character string naming a file, or a connection. "" indicates output to the standard output connection. |
| eol      | the character(s) to print at the end of each line (row).                                                         |
| relation | The name of the relation to be written in the file.                                                              |

## Details

relation will be passed through [make.names](#) before writing to the file, in an attempt to it them acceptable to Weka, and column names what do not start with an alphabetic character will have X prepended.

However, the references say that ARFF files are ASCII files, and that encoding is not enforced.

## References

## See Also

[read.arff](#); functions `write.arff` and `read.arff` in package **RWeka** which provide some support for logicals via conversion to or from factors.

## Examples

```
write.arff(iris, file = "")
```

---

|           |                         |
|-----------|-------------------------|
| write.dbf | <i>Write a DBF File</i> |
|-----------|-------------------------|

---

**Description**

The function tries to write a data frame to a DBF file.

**Usage**

```
write.dbf(dataframe, file, factor2char = TRUE, max_nchar = 254)
```

**Arguments**

|             |                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| dataframe   | a data frame object.                                                                                                                    |
| file        | a file name to be written to.                                                                                                           |
| factor2char | logical, default TRUE, convert factor columns to character: otherwise they are written as the internal integer codes.                   |
| max_nchar   | The maximum number of characters allowed in a character field. Strings which exceed this will be truncated with a warning. See Details. |

**Details**

Dots in column names are replaced by underlines in the DBF file, and names are truncated to 11 characters.

Only vector columns of classes "logical", "numeric", "integer", "character", "factor" and "Date" can be written. Other columns should be converted to one of these.

Maximum precision (number of digits including minus sign and decimal sign) for numeric is 19 - scale (digits after the decimal sign) which is calculated internally based on the number of digits before the decimal sign.

The original DBASE format limited character fields to 254 bytes. It is said that Clipper and FoxPro can read up to 32K, and it is possible to write a reader that could accept up to 65535 bytes. (The documentation suggests that only ASCII characters can be assumed to be supported.) Readers expecting the older standard (which includes Excel 2003, Access 2003 and OpenOffice 2.0) will truncate the field to the maximum width modulo 256, so increase max\_nchar only if you are sure the intended reader supports wider character fields.

**Value**

Invisible NULL.

**Note**

Other applications have varying abilities to read the data types used here. Microsoft Access reads "numeric", "integer", "character" and "Date" fields, including recognizing missing values, but not "logical" (read as 0, -1). Microsoft Excel understood all possible types but did not interpret missing values in character fields correctly (showing them as character nuls).

```

---

write.dta

*Write Files in Stata Binary Format*

---

## Description

Writes the data frame to file in the Stata binary format. Does not write array variables unless they can be [drop](#)-ed to a vector.

Frozen: will not support Stata formats after 10 (also used by Stata 11).

## Usage

```
write.dta(dataframe, file, version = 7L,
 convert.dates = TRUE, tz = "GMT",
 convert.factors = c("labels", "string", "numeric", "codes"))
```

## Arguments

|                 |                                                                                       |
|-----------------|---------------------------------------------------------------------------------------|
| dataframe       | a data frame.                                                                         |
| file            | character string giving filename.                                                     |
| version         | integer: Stata version: 6, 7, 8 and 10 are supported, and 9 is mapped to 8, 11 to 10. |
| convert.dates   | logical: convert Date and POSIXct objects: see section ‘Dates’.                       |
| tz              | timezone for date conversion.                                                         |
| convert.factors | how to handle factors.                                                                |

## Details

The major difference between supported file formats in Stata versions is that version 7.0 and later allow 32-character variable names (5 and 6 were restricted to 8-character names). The `abbreviate` function is used to trim variable names to the permitted length. A warning is given if this is needed and it is an error for the abbreviated names not to be unique. Each version of Stata is claimed to be able to read all earlier formats.

The columns in the data frame become variables in the Stata data set. Missing values are handled correctly.

There are four options for handling factors. The default is to use Stata 'value labels' for the factor levels. With `convert.factors = "string"`, the factor levels are written as strings (the name of the value label is taken from the `"val.labels"` attribute if it exists or the variable name otherwise). With `convert.factors = "numeric"` the numeric values of the levels are written, or NA if they cannot be coerced to numeric. Finally, `convert.factors = "codes"` writes the underlying integer codes of the factors. This last used to be the only available method and is provided largely for backwards compatibility.

If the `"label.table"` attribute contains value labels with names not already attached to a variable (not the variable name or name from `"val.labels"`) then these will be written out as well.

If the `"datalabel"` attribute contains a string, it is written out as the dataset label otherwise the dataset label is "Written by R. ".

If the `"expansion.table"` attribute exists expansion fields are written. This attribute should contain a `list` where each element is `character` vector of length three. The first vector element contains the name of a variable or `"_dta"` (meaning the dataset). The second element contains the characteristic name. The third contains the associated data.

If the `"val.labels"` attribute contains a `character` vector with a string label for each value then this is written as the value labels. Otherwise the variable names are used.

If the `"var.labels"` attribute contains a `character` vector with a string label for each variable then this is written as the variable labels. Otherwise the variable names are repeated as variable labels.

For Stata 8 or later use the default `version = 7` – the only advantage of Stata 8 format over 7 is that it can represent multiple different missing value types, and R doesn't have them. Stata 10/11 allows longer format lists, but R does not make use of them.

Note that the Stata formats are documented to use ASCII strings – R does not enforce this, but use of non-ASCII character strings will not be portable as the encoding is not recorded. Up to 244 bytes are allowed in character data, and longer strings will be truncated with a warning.

Stata uses some large numerical values to represent missing values. This function does not currently check, and hence integers greater than 2147483620 and doubles greater than 8.988e+307 may be misinterpreted by Stata.

## Value

NULL

## Dates

Unless disabled by argument `convert.dates = FALSE`, R date and date-time objects (POSIXt classes) are converted into the Stata date format, the number of days since 1960-01-01. (For date-time objects this may lose information.) Stata can be told that these are dates by

```
format xdate %td;
```

It is possible to pass objects of class POSIXct to Stata to be treated as one of its versions of date-times. Stata uses the number of milliseconds since 1960-01-01, either excluding (format %tc) or counting (format %tC) leap seconds. So either an object of class POSIXct can be passed to Stata with `convert.dates = FALSE` and converted in Stata, or 315619200 should be added and then multiplied by 1000 before passing to `write.dta` and assigning format %tc. Stata's comments on the first route are at <https://www.stata.com/manuals13/ddatetime.pdf>, but at the time of writing were wrong: R uses POSIX conventions and hence does not count leap seconds.

### Examples

```
write.dta(swiss, swissfile <- tempfile())
read.dta(swissfile)
```

---

write.foreign

*Write Text Files and Code to Read Them*

---

### Description

This function exports simple data frames to other statistical packages by writing the data as free-format text and writing a separate file of instructions for the other package to read the data.

### Usage

```
write.foreign(df, datafile, codefile,
 package = c("SPSS", "Stata", "SAS"), ...)
```

### Arguments

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>df</code>       | A data frame                                              |
| <code>datafile</code> | Name of file for data output                              |
| <code>codefile</code> | Name of file for code output                              |
| <code>package</code>  | Name of package                                           |
| <code>...</code>      | Other arguments for the individual writeForeign functions |

## Details

The work for this function is done by `foreign::writeForeignStata`, `foreign::writeForeignSAS` and `foreign::writeForeignSPSS`. To add support for another package, eg `Systat`, create a function `writeForeignSystat` with the same first three arguments as `write.foreign`. This will be called from `write.foreign` when `package="Systat"`.

Numeric variables and factors are supported for all packages: dates and times (`Date`, `dates`, `date`, and `POSIXt` classes) and logical vectors are also supported for `SAS` and characters are supported for `SPSS`.

For `package="SAS"` there are optional arguments `dataname = "rdata"` taking a string that will be the `SAS` data set name, `validvarname` taking either `"V6"` or `"V7"`, and `libpath = NULL` taking a string that will be the directory where the target `SAS` dataset will be written when the generated `SAS` code been run.

For `package="SPSS"` there is an optional argument `maxchars = 32L` taking an integer that causes the variable names (not variable labels) to be abbreviated to not more than `maxchars` chars. For compatibility with `SPSS` version 12 and before, change this to `maxchars = 8L`. In single byte locales with `SPSS` versions 13 or later, this can be set to `maxchars = 64L`.

For `package="SPSS"`, as a side effect, the decimal indicator is always set by `SET DECIMAL=DOT`, which may override user settings of the indicator or its default derived from the current locale.

## Value

Invisible `NULL`.

## Author(s)

Thomas Lumley and Stephen Weigand

## Examples

```
Not run:
datafile <- tempfile()
codefile <- tempfile()
write.foreign(esoph, datafile, codefile, package="SPSS")
file.show(datafile)
file.show(codefile)
unlink(datafile)
unlink(codefile)

End(Not run)
```

## Chapter 23

# The lattice package

---

A.01 Lattice

*Lattice Graphics*

---

### Description

The **lattice** add-on package is an implementation of Trellis graphics for R. It is a powerful and elegant high-level data visualization system with an emphasis on multivariate data. It is designed to meet most typical graphics needs with minimal tuning, but can also be easily extended to handle most nonstandard requirements.

### Details

Trellis Graphics, originally developed for S and S-PLUS at the Bell Labs, is a framework for data visualization developed by R. A. Becker, W. S. Cleveland, et al, extending ideas presented in Cleveland's 1993 book *Visualizing Data*. The Lattice API is based on the original design in S, but extends it in many ways.

The Lattice user interface primarily consists of several 'high-level' generic functions (listed below in the "See Also" section), each designed to create a particular type of display by default. Although the functions produce different output, they share many common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for [xyplot](#), which also includes a discussion of the important topics of *conditioning* and control of the Trellis layout. Features specific to other high-level functions are documented in their respective help pages.

Lattice employs an extensive system of user-controllable settings to determine the look and feel of the displays it produces. To learn how to use and customize the graphical parameters used by lattice, see [trellis.par.set](#). For other settings, see [lattice.options](#). The default graphical settings are (potentially) different for different graphical devices. To learn how to initialize new devices with the desired settings or change the settings of the current device, see [trellis.device](#).

It is usually unnecessary, but sometimes important to be able to plot multiple lattice plots on a single page. Such capabilities are described in the [print.trellis](#) help page. See [update.trellis](#) to learn about manipulating a "trellis" object. Tools to augment lattice plots after they are drawn (including [locator](#)-like functionality) are described in the [trellis.focus](#) help page.

The online documentation accompanying the package is complete, and effort has been made to present the help pages in a logical sequence, so that one can learn how to use lattice by reading

the PDF reference manual available at <https://cran.r-project.org/package=lattice>. However, the format in which the online documentation is written and the breadth of topics covered necessarily makes it somewhat terse and less than ideal as a first introduction. For a more gentle introduction, a book on lattice is available as part of Springer's 'Use R' series; see the "References" section below.

### Note

High-level **lattice** functions like `xyplot` are different from traditional R graphics functions in that they do not perform any plotting themselves. Instead, they return an object, of class "trellis", which has to be then `print`-ed or `plot`-ted to create the actual plot. Due to R's automatic printing rule, it is usually not necessary to explicitly carry out the second step, and **lattice** functions appear to behave like their traditional counterparts. However, the automatic plotting is suppressed when the high-level functions are called inside another function (most often `source`) or in other contexts where automatic printing is suppressed (e.g., `for` or `while` loops). In such situations, an explicit call to `print` or `plot` is required.

The **lattice** package is based on the Grid graphics engine and requires the **grid** add-on package. One consequence of this is that it is not (readily) compatible with traditional R graphics tools. In particular, changing `par()` settings usually has no effect on Lattice plots; **lattice** provides its own interface for querying and modifying an extensive set of graphical and non-graphical settings.

Bell Lab's Trellis Page contains several documents outlining the use of Trellis graphics; these provide a holistic introduction to the Trellis paradigm: <http://web.archive.org/web/20081020164041/http://cm.bell-labs.com/cm/ms/departments/sia/project/trellis/display.writing.html>

### See Also

The following is a list of high-level functions in the **lattice** package and their default displays. In all cases, the actual display is produced by the so-called "panel" function, which has a suitable default, but can be substituted by an user defined function to create customized displays. In many cases, the default panel function will itself have many optional arguments to customize its output. The default panel functions are named as "panel." followed by the name of the corresponding high-level function; i.e., the default panel function for `xyplot` is `panel.xyplot`, the one for `histogram` is `panel.histogram`, etc. Each default panel function has a separate help page, linked from the help pages of the corresponding high-level function. Although documented separately, arguments to these panel functions can be supplied directly to the high-level functions, which will pass on the arguments appropriately.

#### Univariate:

`barchart`: Bar plots.

**bwplot:** Box-and-whisker plots.

**densityplot:** Kernel density estimates.

**dotplot:** Cleveland dot plots.

**histogram:** Histograms.

**qqmath:** Theoretical quantile plots.

**stripplot:** One-dimensional scatterplots.

#### **Bivariate:**

**qq:** Quantile plots for comparing two distributions.

**xyplot:** Scatterplots and time-series plots (and potentially a lot more).

#### **Trivariate:**

**levelplot:** Level plots (similar to **image** plots).

**contourplot:** Contour plots.

**cloud:** Three-dimensional scatter plots.

**wireframe:** Three-dimensional surface plots (similar to **persp** plots).

#### **Hypervariate:**

**splom:** Scatterplot matrices.

**parallel:** Parallel coordinate plots.

#### **Miscellaneous:**

**rfs:** Residual and fitted value plots (also see **oneway**).

**tmd:** Tukey Mean-Difference plots.

In addition, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in **panel.functions**. Lattice also provides a collection of convenience functions that correspond to the traditional graphics primitives **lines**, **points**, etc. These are implemented using Grid graphics, but try to be as close to the traditional versions as possible in terms of their argument list. These functions have names like **llines** or **panel.lines** and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Finally, many useful enhancements that extend the Lattice system are available in the **latticeExtra** package.

### **Examples**

```
Not run:

Show brief history of changes to lattice, including
a summary of new features.

RShowDoc("NEWS", package = "lattice")

End(Not run)
```

**Description**

This help page documents several commonly used high-level Lattice functions. `xyplot` produces bivariate scatterplots or time-series plots, `bwplot` produces box-and-whisker plots, `dotplot` produces Cleveland dot plots, `barchart` produces bar plots, and `stripplot` produces one-dimensional scatterplots. All these functions, along with other high-level Lattice functions, respond to a common set of arguments that control conditioning, layout, aspect ratio, legends, axis annotation, and many other details in a consistent manner. These arguments are described extensively in this help page, and should be used as the reference for other high-level functions as well.

For control and customization of the actual display in each panel, the help page of the respective default panel function will often be more informative. In particular, these help pages describe many arguments commonly used when calling the corresponding high-level function but are specific to them.

**Usage**

```
xyplot(x, data, ...)
dotplot(x, data, ...)
barchart(x, data, ...)
stripplot(x, data, ...)
bwplot(x, data, ...)

S3 method for class 'formula'
xyplot(x,
 data,
 allow.multiple = is.null(groups) || outer,
 outer = !is.null(groups),
 auto.key = lattice.getOption("default.args")$auto.key,
 aspect = "fill",
 panel = lattice.getOption("panel.xyplot"),
 prepanel = NULL,
 scales = list(),
 strip = TRUE,
 groups = NULL,
 xlab,
 xlim,
 ylab,
 ylim,
 drop.unused.levels = lattice.getOption("drop.unused.levels"),
 ...,
 lattice.options = NULL,
 default.scales,
 default.prepanel = lattice.getOption("prepanel.default.xyplot"),
 subscripts = !is.null(groups),
 subset = TRUE)

S3 method for class 'data.frame'
```

```
xyplot(x, data = NULL, formula = data, ...)

S3 method for class 'formula'
dotplot(x,
 data,
 panel = lattice.getOption("panel.dotplot"),
 default.prepanel = lattice.getOption("prepanel.default.dotplot"),
 ...)

S3 method for class 'data.frame'
dotplot(x, data = NULL, formula = data, ...)

S3 method for class 'formula'
barchart(x,
 data,
 panel = lattice.getOption("panel.barchart"),
 default.prepanel = lattice.getOption("prepanel.default.barchart"),
 box.ratio = 2,
 ...)

S3 method for class 'data.frame'
barchart(x, data = NULL, formula = data, ...)

S3 method for class 'formula'
stripplot(x,
 data,
 panel = lattice.getOption("panel.stripplot"),
 default.prepanel = lattice.getOption("prepanel.default.stripplot"),
 ...)

S3 method for class 'data.frame'
stripplot(x, data = NULL, formula = data, ...)

S3 method for class 'formula'
bwplot(x,
 data,
 allow.multiple = is.null(groups) || outer,
 outer = FALSE,
 auto.key = lattice.getOption("default.args")$auto.key,
 aspect = "fill",
 panel = lattice.getOption("panel.bwplot"),
 prepanel = NULL,
 scales = list(),
 strip = TRUE,
 groups = NULL,
 xlab,
 xlim,
 ylab,
 ylim,
 box.ratio = 1,
 horizontal = NULL,
 drop.unused.levels = lattice.getOption("drop.unused.levels"),
```

```

...,
lattice.options = NULL,
default.scales,
default.prepanel = lattice.getOption("prepanel.default.bwplot"),
subscripts = !is.null(groups),
subset = TRUE)

S3 method for class 'data.frame'
bwplot(x, data = NULL, formula = data, ...)

```

## Arguments

- x** All high-level function in **lattice** are generic. **x** is the object on which method dispatch is carried out.
- For the "formula" methods, **x** must be a formula describing the primary variables (used for the per-panel display) and the optional conditioning variables (which define the subsets plotted in different panels) to be used in the plot. Conditioning is described in the "Details" section below.
- For the functions documented here, the formula is generally of the form  $y \sim x \mid g1 * g2 * \dots$  (or equivalently,  $y \sim x \mid g1 + g2 + \dots$ ), indicating that plots of  $y$  (on the y-axis) versus  $x$  (on the x-axis) should be produced conditional on the variables  $g1, g2, \dots$ . Here  $x$  and  $y$  are the primary variables, and  $g1, g2, \dots$  are the conditioning variables. The conditioning variables may be omitted to give a formula of the form  $y \sim x$ , in which case the plot will consist of a single panel with the full dataset. The formula can also involve expressions, e.g., `sqrt()`, `log()`, etc. See the data argument below for rules regarding evaluation of the terms in the formula.
- With the exception of `xyplot`, the functions documented here may also be supplied a formula of the form  $\sim x \mid g1 * g2 * \dots$ . In that case,  $y$  defaults to `names(x)` if  $x$  is named, and a factor with a single level otherwise.
- Cases where  $x$  is not a formula is handled by appropriate methods. The numeric methods are equivalent to a call with no left hand side and no conditioning variables in the formula. For `barchart` and `dotplot`, non-trivial methods exist for tables and arrays, documented at [barchart.table](#).
- The conditioning variables  $g1, g2, \dots$  must be either factors or shingles. Shingles provide a way of using numeric variables for conditioning; see the help page of [shingle](#) for details. Like factors, they have a "levels" attribute, which is used in producing the conditional plots. If necessary, numeric conditioning variables are converted to shingles using the `shingle` function; however, using [equal.count](#) may be more appropriate in many cases. Character variables are coerced to factors.
- Extended formula interface:** As a useful extension of the interface described above, the primary variable terms (both the LHS  $y$  and RHS  $x$ ) may consist of multiple terms separated by a '+' sign, e.g.,  $y1 + y2 \sim x \mid a * b$ . This formula would be taken to mean that the user wants to plot both  $y1 \sim x \mid a * b$  and  $y2 \sim x \mid a * b$ , but with the  $y1 \sim x$  and  $y2 \sim x$  superposed in each panel. The two groups will be distinguished by different graphical parameters. This is essentially what the groups argument (see below) would produce, if  $y1$  and  $y2$  were concatenated to produce a longer vector, with the groups argument being an indicator of which rows come from which variable. In fact, this is exactly what

is done internally using the [reshape](#) function. This feature cannot be used in conjunction with the `groups` argument.

To interpret `y1 + y2` as a sum, one can either set `allow.multiple=FALSE` or use `I(y1+y2)`.

A variation on this feature is when the `outer` argument is set to `TRUE`. In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

**Primary variables:** The `x` and `y` variables should both be numeric in `xyplot`, and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here, exactly one of `x` and `y` should be numeric, and the other a factor or shingle. Which of these will happen is determined by the `horizontal` argument — if `horizontal=TRUE`, then `y` will be coerced to be a factor or shingle, otherwise `x`. The default value of `horizontal` is `FALSE` if `x` is a factor or shingle, `TRUE` otherwise. (The functionality provided by `horizontal=FALSE` is not S-compatible.)

Note that the `x` argument used to be called `formula` in earlier versions (when the high-level functions were not generic and the `formula` method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but instead be the first (unnamed) argument.

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>           | For the <code>formula</code> methods, a data frame (or more precisely, anything that is a valid <code>envir</code> argument in <a href="#">eval</a> , e.g., a list or an environment) containing values for any variables in the formula, as well as <code>groups</code> and <code>subset</code> if applicable. If not found in <code>data</code> , or if <code>data</code> is unspecified, the variables are looked for in the environment of the formula. For other methods (where <code>x</code> is not a formula), <code>data</code> is usually ignored, often with a warning if it is explicitly specified.                                                                                                                                                                                                                                                                                                                               |
| <code>formula</code>        | The formula to be used for the <code>"data.frame"</code> methods. See documentation for argument <code>x</code> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>allow.multiple</code> | Logical flag specifying whether the extended formula interface described above should be in effect. Defaults to <code>TRUE</code> whenever sensible.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>outer</code>          | Logical flag controlling what happens with formulas using the extended interface described above (see the entry for <code>x</code> for details). Defaults to <code>FALSE</code> , except when <code>groups</code> is explicitly specified or grouping does not make sense for the default panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>box.ratio</code>      | Applicable to <code>barchart</code> and <code>bwplot</code> . Specifies the ratio of the width of the rectangles to the inter-rectangle space. See also the <code>box.width</code> argument in the respective default panel functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>horizontal</code>     | Logical flag applicable to <code>bwplot</code> , <code>dotplot</code> , <code>barchart</code> , and <code>stripplot</code> . Determines which of <code>x</code> and <code>y</code> is to be a factor or shingle ( <code>y</code> if <code>TRUE</code> , <code>x</code> otherwise). Defaults to <code>FALSE</code> if <code>x</code> is a factor or shingle, <code>TRUE</code> otherwise. This argument is used to process the arguments to these high-level functions, but more importantly, it is passed as an argument to the panel function, which is expected to use it as appropriate.<br><br>A potentially useful component of <code>scales</code> in this case may be <code>abbreviate = TRUE</code> , in which case long labels which would usually overlap will be abbreviated. <code>scales</code> could also contain a <code>minlength</code> argument in this case, which would be passed to the <code>abbreviate</code> function. |

**Common arguments:** The following arguments are common to all the functions documented here, as well as most other high-level Trellis functions. These are not documented elsewhere, except to override the usage given here.

**panel**

Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see “Details”), the corresponding *x* and *y* variables (or other variables, as appropriate, in the case of other high-level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the `panel` argument. The argument may be a function object or a character string giving the name of a predefined function. Each high-level function has its own default panel function, named as “`panel.`” followed by the name of the corresponding high-level function (e.g., `panel.xyplot`, `panel.barchart`, etc).

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named *x* and *y*, which would be provided by the conditioning process. It can also have other arguments. It is useful to know in this context that all arguments passed to a high-level Lattice function (such as `xyplot`) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a `...` argument. Such extra arguments typically control graphical parameters, but other uses are also common. See documentation for individual panel functions for specifics.

Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the *x* and *y* arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, as there are several predefined panel functions which can help; for example, `panel.grid`, `panel.loess`, etc. There are also some grid-compatible replacements of commonly used traditional graphics functions useful for this purpose. For example, lines can be replaced by `llines` (or equivalently, `panel.lines`). Note that traditional graphics functions like `lines` will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the `groups` argument is not `NULL`. In that case, the panel function should also accept arguments named `groups` and `subscripts` (see below for details). A useful panel function predefined for use in such cases is `panel.superpose`, which can be combined with different `panel.groups` functions to determine what is plotted for each group. See the “Examples” section for an interaction plot constructed in this way. Several other panel functions can also handle the `groups` argument, including the default ones for `xyplot`, `barchart`, `dotplot`, and `stripplot`.

Even when `groups` is not present, the panel function can have `subscripts` as a formal argument. In either case, the `subscripts` argument passed to the panel function are the indices of the *x* and *y* data for that panel in the original data, BEFORE taking into account the effect of the subset argument. Note that `groups` remains unaffected by any subsetting operations, so `groups[subscripts]` gives the values of `groups` that correspond to the data in that panel.

This interpretation of `subscripts` does not hold when the extended formula interface is in use (i.e., when `allow.multiple` is in effect). A comprehensive description would be too complicated (details can be found in the source code of the function `latticeParseFormula`), but in short, the extended interface works by creating an artificial grouping variable that is longer than the original data frame, and consequently, `subscripts` needs to refer to rows beyond those in

the original data. To further complicate matters, the artificial grouping variable is created after any effect of subset, in which case subscripts may have no relationship with corresponding rows in the original data frame.

One can also use functions called `panel.number` and `packet.number`, representing panel order and packet order respectively, inside the `panel` function (as well as the `strip` function or while interacting with a lattice display using `trellis.focus` etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using `perm.cond` and `index.cond` respectively), in which case `packet.number` gives the index corresponding to the ‘natural’ ordering of that combination of levels of the conditioning variables.

`panel.xyplot` has an argument called `type` which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to `xyplot` directly). In the event that a groups variable is used, `panel.xyplot` calls `panel.superpose`, arguments of which can also be passed directly to `xyplot`. Panel functions for `bwplot` and friends should have an argument called `horizontal` to account for the cases when `x` is the factor or shingle.

**aspect** This argument controls the physical aspect ratio of the panels, which is usually the same for all the panels. It can be specified as a ratio (vertical size/horizontal size) or as a character string. In the latter case, legitimate values are “fill” (the default) which tries to make the panels as big as possible to fill the available space; “xy”, which computes the aspect ratio based on the 45 degree banking rule (see `banking`); and “iso” for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a `prepanel` function is specified and it returns components `dx` and `dy`, these are used for banking calculations. Otherwise, values from the default `prepanel` function are used. Not all default `prepanel` functions produce sensible banking calculations.

**groups** A variable or expression to be evaluated in data, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if `groups` is specified, then `groups` along with `subscripts` is passed to the `panel` function, which is expected to handle these arguments. For high level functions where grouping is appropriate, the default panel functions can handle grouping.

It is very common to use a key (legend) when a grouping variable is specified. See entries for `key`, `auto.key` and `simpleKey` for how to draw a key.

**auto.key** A logical, or a list containing components to be used as arguments to `simpleKey`. The default can be set using `lattice.options`.

`auto.key = TRUE` is equivalent to `auto.key = list()`, in which case `simpleKey` is called with a set of default arguments (which may depend on the relevant high-level function). Most valid components to the `key` argument can be specified in this manner, as `simpleKey` will simply add unrecognized arguments to the list it produces.

`auto.key` is typically used to automatically produce a suitable legend in conjunction with a grouping variable. If `auto.key = TRUE`, a suitable legend will

be drawn if a `groups` argument is also provided, and not otherwise. In list form, `auto.key` will modify the default legend thus produced. For example, `auto.key=list(columns = 2)` will create a legend split into two columns (`columns` is documented in the entry for `key`).

More precisely, if `auto.key` is not `FALSE`, `groups` is non-null, and there is no `key` or `legend` argument specified in the call, a key is created with `simpleKey` with `levels(groups)` as the first (text) argument. (Note: this may not work in all high-level functions, but it does work for the ones where grouping makes sense with the default panel function). If `auto.key` is provided as a list and includes a text component, then that is used instead as the text labels in the key, and the key is drawn even if `groups` is not specified.

Note that `simpleKey` uses the default settings (see `trellis.par.get`) to determine the graphical parameters in the key, so the resulting legend will be meaningful only if the same settings are used in the plot as well. The `par.settings` argument, possibly in conjunction with `simpleTheme`, may be useful to temporarily modify the default settings for this purpose.

One disadvantage to using `key` (or even `simpleKey`) directly is that the graphical parameters used in the key are absolutely determined at the time when the "trellis" object is created. Consequently, if a plot once created is re-plotted with different settings, the original parameter settings will be used for the key even though the new settings are used for the actual display. However, with `auto.key`, the key is actually created at plotting time, so the settings will match.

`prepanel`

A function that takes the same arguments as the `panel` function and returns a list, possibly containing components named `xlim`, `ylim`, `dx`, and `dy` (and less frequently, `xat` and `yat`). The return value of a user-supplied `prepanel` function need not contain all these components; in case some are missing, they are replaced by the component-wise defaults.

The `xlim` and `ylim` components are similar to the high level `xlim` and `ylim` arguments (i.e., they are usually a numeric vector of length 2 defining a range, or a character vector representing levels of a factor). If the `xlim` and `ylim` arguments are not explicitly specified (possibly as components in `scales`) in the high-level call, then the actual limits of the panels are guaranteed to include the limits returned by the `prepanel` function. This happens globally if the `relation` component of `scales` is "same", and on a per-panel basis otherwise.

The `dx` and `dy` components are used for banking computations in case `aspect` is specified as "xy". See documentation of `banking` for details.

If `xlim` or `ylim` is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first `n` integers, where `n` is the length of `xlim` or `ylim`, as the case may be. The elements of the character vector are used as the default labels for these `n` integers. Thus, to make this information consistent between panels, the `xlim` or `ylim` values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component `xat` or `yat` may be returned by the `prepanel` function, which should be a subset of `1:n`, indicating which of the `n` values (levels) are actually represented in the panel. This is useful when calculating the limits with `relation="free"` or `relation="sliced"` in `scales`.

The `prepanel` function is responsible for providing a meaningful return value when the `x`, `y` (etc.) variables are zero-length vectors. When nothing else is appropriate, values of `NA` should be returned for the `xlim` and `ylim` components.

`strip`

A logical flag or function. If `FALSE`, strips are not drawn. Otherwise, strips

are drawn using the `strip` function, which defaults to `strip.default`. See documentation of `strip.default` to see the arguments that are available to the `strip` function. This description also applies to the `strip.left` argument (see ... below), which can be used to draw strips on the left of each panel (useful for wide short panels, e.g., in time-series plots).

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>xlab</code>   | Character or expression (or a "grob") giving label(s) for the x-axis. Generally defaults to the expression for <code>x</code> in the formula defining the plot. Can be specified as <code>NULL</code> to omit the label altogether. Finer control is possible, as described in the entry for <code>main</code> , with the modification that if the <code>label</code> component is omitted from the list, it is replaced by the default <code>xlab</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>ylab</code>   | Character or expression (or "grob") giving label for the y-axis. Generally defaults to the expression for <code>y</code> in the formula defining the plot. Finer control is possible, see entries for <code>main</code> and <code>xlab</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>scales</code> | Generally a list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in <code>name=value</code> form, and may also contain two other lists called <code>x</code> and <code>y</code> of the same form (described below). Components of <code>x</code> and <code>y</code> affect the respective axes only, while those in <code>scales</code> affect both. When parameters are specified in both lists, the values in <code>x</code> or <code>y</code> are used. Note that certain high-level functions have defaults that are specific to a particular axis (e.g., <code>bwplot</code> has <code>alternating=FALSE</code> for the categorical axis only); these can only be overridden by an entry in the corresponding component of <code>scales</code> . As a special exception, <code>scales</code> (or its <code>x</code> and <code>y</code> components) can also be a character string, in which case it is interpreted as the <code>relation</code> component. |

The possible components are :

`relation` A character string that determines how axis limits are calculated for each panel. Possible values are "same" (default), "free" and "sliced". For `relation="same"`, the same limits, usually large enough to encompass all the data, are used for all the panels. For `relation="free"`, limits for each panel is determined by just the points in that panel. Behavior for `relation="sliced"` is similar, except that the length (max - min) of the scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be controlled by the `prepanel` function, which can be overridden by `xlim`, `ylim` or `scales$limits` (except when `relation="sliced"`, in which case explicitly specified limits are ignored with a warning). When `relation` is "free", `xlim` or `ylim` can be a list, in which case it is treated as if its components were the limit values obtained from the `prepanel` calculations for each panel (after being replicated if necessary).

`tick.number` An integer, giving the suggested number of intervals between ticks. This is ignored for a factor, shingle, or character vector, for in these cases there is no natural rule for leaving out some of the labels. But see `xlim`.

`draw` A logical flag, defaulting to `TRUE`, that determines whether to draw the axis (i.e., tick marks and labels) at all.

`alternating` Usually a logical flag specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, `alternating` can also be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers

- 0: do not draw tick labels
- 1: bottom/left

- 2: top/right
- 3: both.

alternating applies only when `relation="same"`. The default is `TRUE`, or equivalently, `c(1, 2)`

`limits` Same as `xlim` and `ylim`.

`at` The location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.

`labels` Vector of labels (characters or expressions) to go along with `at`. Can also be a list like `at`.

`cex` A numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top labels separately.

`font`, `fontface`, `fontfamily` Specifies the font to be used for axis labels.

`lineheight` Specifies the line height parameter (height of line as a multiple of the size of text); relevant for multi-line labels. (This is currently ignored for `cloud`.)

`tck` Usually a numeric scalar controlling the length of tick marks. Can also be a vector of length 2, to control the length of left/bottom and right/top tick marks separately.

`col` Color of tick marks and labels.

`rot` Angle (in degrees) by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top axes separately.

`abbreviate` A logical flag, indicating whether to abbreviate the labels using the `abbreviate` function. Can be useful for long labels (e.g., in factors), especially on the x-axis.

`minlength` Argument passed to `abbreviate` if `abbreviate=TRUE`.

`log` Controls whether the corresponding variable (x or y) will be log transformed before being passed to the panel function. Defaults to `FALSE`, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, `TRUE` (which is equivalent to 10), and `"e"` (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is in reality a transformation of the data, not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., `scales=list(x = list(log = 2))` is equivalent to  $y \sim \log_2(x)$ .

See entry for `equispaced.log` below for details on how to control axis labeling.

`equispaced.log` A logical flag indicating whether tick mark locations should be equispaced when 'log scales' are in use. Defaults to `TRUE`.

Tick marks are always labeled in the original (untransformed) scale, but this makes the choice of tick mark locations nontrivial. If `equispaced.log` is `FALSE`, the choice made is similar to how log scales are annotated in traditional graphics. If `TRUE`, tick mark locations are chosen as 'pretty' equispaced values in the transformed scale, and labeled in the form `"base^loc"`, where `base` is the base of the logarithm transformation, and `loc` are the locations in the transformed scale.

See also `xscale.components.logpower` in the **latticeExtra** package.

`format` The format to use for POSIXct variables. See `strptime` for description of valid values.

`axis` A character string, `"r"` (default) or `"i"`. In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 | Note that much of the function of scales is accomplished by <code>pscales</code> in <a href="#">splom</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>subscripts</code>         | A logical flag specifying whether or not a vector named <code>subscripts</code> should be passed to the <code>panel</code> function. Defaults to <code>FALSE</code> , unless <code>groups</code> is specified, or if the <code>panel</code> function accepts an argument named <code>subscripts</code> . This argument is useful if one wants the <code>subscripts</code> to be passed on even if these conditions do not hold; a typical example is when one wishes to augment a Lattice plot after it has been drawn, e.g., using <a href="#">panel.identify</a> .                                                                                                                                                                                                                       |
| <code>subset</code>             | An expression that evaluates to a logical or integer indexing vector. Like <code>groups</code> , it is evaluated in <code>data</code> . Only the resulting rows of data are used for the plot. If <code>subscripts</code> is <code>TRUE</code> , the <code>subscripts</code> provided to the <code>panel</code> function will be indices referring to the rows of data prior to the subsetting. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the <code>drop.unused.levels</code> argument.                                                                                                                                                                                                                                  |
| <code>xlim</code>               | Normally a numeric vector (or a <code>DateTime</code> object) of length 2 giving left and right limits for the x-axis, or a character vector, expected to denote the levels of <code>x</code> . The latter form is interpreted as a range containing <code>c(1, length(xlim))</code> , with the character vector determining labels at tick positions <code>1:length(xlim)</code> .<br><br><code>xlim</code> could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaningful only when <code>scales\$x\$relation</code> is <code>"free"</code> , in which case these are treated as if they were the corresponding limit components returned by <code>prepanel</code> calculations.              |
| <code>ylim</code>               | Similar to <code>xlim</code> , applied to the y-axis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>drop.unused.levels</code> | A logical flag indicating whether the unused levels of factors will be dropped, usually relevant when a subsetting operation is performed or an <a href="#">interaction</a> is created. Unused levels are usually dropped, but it is sometimes appropriate to suppress dropping to preserve a useful layout. For finer control, this argument could also be list containing components <code>cond</code> and <code>data</code> , both logical, indicating desired behavior for conditioning variables and primary variables respectively. The default is given by <code>lattice.getOption("drop.unused.levels")</code> , which is initially set to <code>TRUE</code> for both components. Note that this argument does not control dropping of levels of the <code>groups</code> argument. |
| <code>default.scales</code>     | A list giving the default values of scales for a particular high-level function. This is rarely of interest to the end-user, but may be helpful when defining other functions that act as a wrapper to one of the high-level Lattice functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>default.prepanel</code>   | A function or character string giving the name of a function that serves as the (component-wise) fallback <code>prepanel</code> function when the <code>prepanel</code> argument is not specified, or does not return all necessary components. The main purpose of this argument is to enable the defaults to be overridden through the use of <a href="#">lattice.options</a> .                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>lattice.options</code>    | A list that could be supplied to <a href="#">lattice.options</a> . These options are applied temporarily for the duration of the call, after which the settings revert back to what they were before. The options are retained along with the object and reused during plotting. This enables the user to attach options settings to the <code>trellis</code> object itself rather than change the settings globally. See also the <code>par.settings</code> argument described below for a similar treatment of graphical settings.                                                                                                                                                                                                                                                       |
| <code>...</code>                | Further arguments, usually not directly processed by the high-level functions documented here, but instead passed on to other functions. Such arguments can                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

be broadly categorized into two types: those that affect all high-level Lattice functions in a similar manner, and those that are meant for the specific panel function being used.

The first group of arguments are processed by a common, unexported function called `trellis.skeleton`. These arguments affect all high-level functions, but are only documented here (except to override the behaviour described here). All other arguments specified in a high-level call, specifically those neither described here nor in the help page of the relevant high-level function, are passed unchanged to the panel function used. By convention, the default panel function used for any high-level function is named as “`panel.`” followed by the name of the high-level function; for example, the default panel function for `bwplot` is `panel.bwplot`. In practical terms, this means that in addition to the help page of the high-level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high-level call.

The effect of the first group of common arguments are as follows:

**as.table:** A logical flag that controls the order in which panels should be displayed: if `FALSE` (the default), panels are drawn left to right, bottom to top (as in a graph); if `TRUE`, left to right, top to bottom (as in a table).

**between:** A list with components `x` and `y` (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). `x` and `y` are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi page display. In other words, it is not possible to use different between values for different pages.

**key:** A list that defines a legend to be drawn on the plot. This list is used as an argument to the `draw.key` function, which produces a “grob” (grid object) eventually plotted by the print method for “trellis” objects. The structure of the legend is constrained in the ways described below.

Although such a list can be and often is created explicitly, it is also possible to generate such a list using the `simpleKey` function; the latter is more convenient but less flexible. The `auto.key` argument can be even more convenient for the most common situation where legends are used, namely, in conjunction with a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by `key`, use the `legend` argument.

The position of the key can be controlled in either of two possible ways. If a component called `space` is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of `space`, which can be one of “top”, “bottom”, “left” and “right”. Alternatively, the key can be positioned inside the plot region by specifying components `x`, `y` and `corner`. `x` and `y` determine the location of the corner of the key given by `corner`, which is usually one of `c(0,0)`, `c(1,0)`, `c(1,1)` and `c(0,1)`, which denote the corners of the unit square. Fractional values are also allowed, in which case `x` and `y` determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key.

`x` and `y` should be numbers between 0 and 1, giving coordinates with respect to the “display area”. Depending on the value of the “`legend.bbox`” option (see `lattice.getOption`), this can be either the full figure region (“full”), or just the region that bounds the panels and strips (“panel”).

The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are deter-

mined by (possibly repeated) components named "rectangles", "lines", "points" or "text". Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The key list itself can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text"s) is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for `rep` below for details on this). The "text" component must have a character or expression vector as its first component, to be used as labels. The length of this vector determines the number of rows.

The graphical components that can be included in key and also in the components named "text", "lines", "points" and "rectangles" (as appropriate) are:

- `cex=1` (text, lines, points)
- `col="black"` (text, rectangles, lines, points)
- `alpha=1` (text, rectangles, lines, points)
- `fill="transparent"` (lines, points)
- `lty=1` (lines)
- `lwd=1` (lines, points)
- `font=1` (text, points)
- `fontface` (text, points)
- `fontfamily` (text, points)
- `pch=8` (lines, points)
- `adj=0` (text)
- `type="l"` (lines)
- `size=5` (rectangles, lines)
- `height=1` (rectangles)
- `lineheight=1` (text)
- `angle=0` (rectangles, but ignored)
- `density=-1` (rectangles, but ignored)

In addition, the component `border` can be included inside the "rect" component to control the border color of the rectangles; when specified at the top level, `border` controls the border of the entire key (see below).

`angle` and `density` are unimplemented. `size` determines the width of columns of rectangles and lines in character widths. `type` is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together. `height` gives heights of rectangles as a fraction of the default.

Other possible components of key are:

`reverse.rows` Logical flag, defaulting to FALSE. If TRUE, all components are reversed *after* being replicated (the details of which may depend on the value of `rep`). This is useful in certain situations, e.g., with a grouped barchart with `stack = TRUE` with the categorical variable on the vertical axis, where the bars in the plot will usually be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom unless `reverse.rows = TRUE`. Note that in this case, unless all columns have the same number of rows, they will no longer be aligned.

between Numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides).

`title` String or expression giving a title for the key.

`rep` Logical flag, defaults to TRUE. By default, it is assumed that all columns in the key (except the "text"s) will have the same number of rows, and all components are replicated to be as long as the longest. This can be suppressed by specifying `rep=FALSE`, in which case the length of each column will be determined by components of that column alone.

`cex.title` Zoom factor for the title.

`lines.title` The amount of vertical space to be occupied by the title in lines (in multiples of itself). Defaults to 2.

`padding.text` The amount of space (padding) to be used above and below each row containing text, in multiples of the default, which is currently  $0.2 * \text{"lines"}$ . This padding is in addition to the normal height of any row that contains text, which is the minimum amount necessary to contain all the text entries.

`background` Background color for the legend. Defaults to the global background color.

`alpha.background` An alpha transparency value between 0 and 1 for the background.

`border` Either a color for the border, or a logical flag. In the latter case, the border color is black if border is TRUE, and no border is drawn if it is FALSE (the default).

`transparent=FALSE` Logical flag, whether legend should have a transparent background.

`just` A character or numeric vector of length one or two giving horizontal and vertical justification for the placement of the legend. See [grid.layout](#) for more precise details.

`columns` The number of column-blocks (drawn side by side) the legend is to be divided into.

`between.columns` Space between column blocks, in addition to `between`.

`divide` Number of point symbols to divide each line when type is "b" or "o" in lines.

**legend:** The legend argument can be useful if one wants to place more than one key. It also allows the use of arbitrary "grob"s (grid objects) as legends.

If used, legend must be a list, with an arbitrary number of components. Each component must be named one of "left", "right", "top", "bottom", or "inside". The name "inside" can be repeated, but not the others. This name will be used to determine the location for that component, and is similar to the space component of key. If key (or colorkey for [levelplot](#) and [wireframe](#)) is specified, their space component must not conflict with the name of any component of legend.

Each component of legend must have a component called `fun`. This can be a "grob", or a function (or the name of a function) that produces a "grob" when called. If this function expects any arguments, they must be supplied as a list in another component called `args`. For components named "inside", there can be additional components called `x`, `y` and `corner`, which work in the same way as for key.

- page:** A function of one argument (page number) to be called after drawing each page. The function must be 'grid-compliant', and is called with the whole display area as the default viewport.
- xlab.top, ylab.right:** Labels for the x-axis on top, and y-axis on the right. Similar to `xlab` and `ylab`, but less commonly used.
- main:** Typically a character string or expression describing the main title to be placed on top of each page. Defaults to `NULL`.  
**main** (as well as `xlab`, `ylab` and `sub`) is usually a character string or an expression that gets used as the label, but can also be a list that controls further details. Expressions are treated as specification of LaTeX-like markup as described in [plotmath](#). The label can be a vector, in which case the components will be spaced out horizontally (or vertically for `ylab`). This feature can be used to provide column or row labels rather than a single axis label. When `main` (etc.) is a list, the actual label should be specified as the `label` component (which may be unnamed if it is the first component). The label can be missing, in which case the default will be used (`xlab` and `ylab` usually have defaults, but `main` and `sub` do not). Further named arguments are passed on to [textGrob](#); this can include arguments controlling positioning like `just` and `rot` as well as graphical parameters such as `col` and `font` (see [gpar](#) for a full list).  
**main**, **sub**, **xlab**, **ylab**, **xlab.top**, and **ylab.right** can also be arbitrary "grob"s (grid graphical objects).
- sub:** Character string or expression (or a list or "grob") for a subtitle to be placed at the bottom of each page. See entry for `main` for finer control options.
- par.strip.text:** A list of parameters to control the appearance of strip text. Notable components are `col`, `cex`, `font`, and `lines`. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contains "\n"-s) or if the default height seems too small or too large.  
 Additionally, the `lineheight` component can control the space between multiple lines. The labels can be abbreviated when shown by specifying `abbreviate = TRUE`, in which case the components `minlength` and `dot` (passed along to the [abbreviate](#) function) can be specified to control the details of how this is done.
- layout:** In general, a conditioning plot in Lattice consists of several panels arranged in a rectangular array, possibly spanning multiple pages. `layout` determines this arrangement.  
**layout** is a numeric vector of length 2 or 3 giving the number of columns, rows, and pages (optional) in a multipanel display. By default, the number of columns is the number of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is `c(0, n)`, where `n` is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, taking into account the aspect ratio of the panels and the device dimensions (via `par("din")`). If `NA` is specified for the number of rows or columns (but not both), that dimension will be filled out according to the number of panels.  
 The number of pages is by default set to as many as is required to plot all the

panels, and so rarely needs to be specified. However, in certain situations the default calculation may be incorrect, and in that case the number of pages needs to be specified explicitly.

**skip:** A logical vector (default FALSE), replicated to be as long as the number of panels (spanning all pages). For elements that are TRUE, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This may be useful for arranging plots in an informative manner.

**strip.left:** `strip.left` can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time-series (or similar) plots. See the entry for `strip` for detailed usage.

**xlab.default, ylab.default:** Fallback default for `xlab` and `ylab` when they are not specified. If NULL, the defaults are parsed from the Trellis formula. This is rarely useful for the end-user, but can be helpful when developing new Lattice functions.

**xscale.components, yscale.components:** Functions that determine axis annotation for the x and y axes respectively. See documentation for [xscale.components.default](#), the default values of these arguments, to learn more.

**axis:** Function responsible for drawing axis annotation. See documentation for [axis.default](#), the default value of this argument, to learn more.

**perm.cond:** An integer vector, a permutation of 1:n, where n is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. `perm.cond` can modify this order. If the trellis display is thought of as an n-dimensional array, then during printing, its dimensions are permuted using `perm.cond` as the `perm` argument does in [aperm](#).

**index.cond:** Whereas `perm.cond` permutes the dimensions of the multidimensional array of panels, `index.cond` can be used to subset (or reorder) margins of that array. `index.cond` can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. `index.cond` can be used to choose a ‘subset’ (in the R sense) of these levels, which is then used as the display order for that variable. If `index.cond` is a list, it has to be as long as the number of conditioning variables, and the i-th component has to be a valid indexing vector for `levels(g_i)`, where `g_i` is the i-th conditioning variable in the plot (note that these levels may not contain all levels of the original variable, depending on the effects of the `subset` and `drop.unused.levels` arguments). In particular, this indexing may repeat levels, or drop some altogether. The result of this indexing determines the order of panels within that conditioning variable. To keep the order of a particular variable unchanged, the corresponding component must be set to TRUE.

Note that the components of `index.cond` are interpreted in the order of the conditioning variables in the original call, and is not affected by `perm.cond`. Another possibility is to specify `index.cond` as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a `...` argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) If there is only

one conditioning variable, the levels of that variable are then sorted so that these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high-level function calls directly, it is more typical to use `perm.cond` and `index.cond` to update an existing "trellis" object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the `update.trellis` method, both can be set to `NULL`, which reverts these back to their defaults.

`par.settings`: A list that could be supplied to `trellis.par.set`. When the resulting object is plotted, these options are applied temporarily for the duration of the plotting, after which the settings revert back to what they were before. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. See also the `lattice.options` argument described above for a similar treatment of non-graphical options.

`plot.args`: A list containing possible arguments to `plot.trellis`, which will be used by the `plot` or `print` methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.

## Details

The high-level functions documented here, as well as other high-level Lattice functions, are generic, with the formula method usually doing the most substantial work. The structure of the plot that is produced is mostly controlled by the formula (implicitly in the case of the non-formula methods). For each unique combination of the levels of the conditioning variables `g1`, `g2`, ..., a separate "packet" is produced, consisting of the points  $(x, y)$  for the subset of the data defined by that combination. The display can be thought of as a three-dimensional array of panels, consisting of one two-dimensional matrix per page. The dimensions of this array are determined by the `layout` argument. If there are no conditioning variables, the plot produced consists of a single packet. Each packet usually corresponds to one panel, but this is not strictly necessary (see the entry for `index.cond` above).

The coordinate system used by **lattice** by default is like a graph, with the origin at the bottom left, with axes increasing to the right and top. In particular, panels are by default drawn starting from the bottom left corner, going right and then up, unless `as.table = TRUE`, in which case panels are drawn from the top left corner, going right and then down. It is possible to set a global preference for the table-like arrangement by changing the default to `as.table=TRUE`; this can be done by setting `lattice.options(default.args = list(as.table = TRUE))`. Default values can be set in this manner for the following arguments: `as.table`, `aspect`, `between`, `page`, `main`, `sub`, `par.strip.text`, `layout`, `skip` and `strip`. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with `g1` varying fastest, followed by `g2`, and so on. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders can be modified using the `index.cond` and `perm.cond` arguments, possibly using the `update` (and other related) method(s).

**Value**

The high-level functions documented here, as well as other high-level Lattice functions, return an object of class "trellis". The `update` method can be used to subsequently update components of the object, and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Note**

Most of the arguments documented here are also applicable for the other high-level functions in the **lattice** package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high-level plot.

**Examples**

```
require(stats)

Tonga Trench Earthquakes

Depth <- equal.count(quakes$depth, number=8, overlap=.1)
xyplot(lat ~ long | Depth, data = quakes)
update(trellis.last.object(),
 strip = strip.custom(strip.names = TRUE, strip.levels = TRUE),
 par.strip.text = list(cex = 0.75),
 aspect = "iso")

Extended formula interface

xyplot(Sepal.Length + Sepal.Width ~ Petal.Length + Petal.Width | Species,
 data = iris, scales = "free", layout = c(2, 2),
 auto.key = list(x = .75, y = .75, corner = c(0.5, 0.5)))

user defined panel functions

states <- data.frame(state.x77,
```

```

 state.name = dimnames(state.x77)[[1]],
 state.region = state.region)
xyplot(Murder ~ Population | state.region, data = states,
 snames = states$state.name,
 panel = function(x, y, subscripts, snames) {
 panel.text(x = x, y = y, labels = snames[subscripts], cex = 1,
 fontfamily = "HersheySans")
 })

Stacked bar chart

barchart(yield ~ variety | site, data = barley,
 groups = year, layout = c(1,6), stack = TRUE,
 auto.key = list(space = "right"),
 ylab = "Barley Yield (bushels/acre)",
 scales = list(x = list(rot = 45)))

bwplot(voice.part ~ height, data = singer, xlab = "Height (inches)")

dotplot(variety ~ yield | year * site, data=barley)

Grouped dot plot showing anomaly at Morris

dotplot(variety ~ yield | site, data = barley, groups = year,
 key = simpleKey(levels(barley$year), space = "right"),
 xlab = "Barley Yield (bushels/acre) ",
 aspect=0.5, layout = c(1,6), ylab=NULL)

stripplot(voice.part ~ jitter(height), data = singer, aspect = 1,
 jitter.data = TRUE, xlab = "Height (inches)")

Interaction Plot

xyplot(decrease ~ treatment, OrchardSprays, groups = rowpos,
 type = "a",
 auto.key =
 list(space = "right", points = FALSE, lines = TRUE))

longer version with no x-ticks

Not run:
bwplot(decrease ~ treatment, OrchardSprays, groups = rowpos,
 panel = "panel.superpose",
 panel.groups = "panel.linejoin",
 xlab = "treatment",
 key = list(lines = Rows(trellis.par.get("superpose.line"),
 c(1:7, 1)),
 text = list(lab = as.character(unique(OrchardSprays$rowpos))),
 columns = 4, title = "Row position"))

End(Not run)

```

## Description

This function handles time series plotting, including cut-and-stack plots. Examples are given of superposing, juxtaposing and styling different time series.

## Usage

```
S3 method for class 'ts'
xyplot(x, data = NULL,
 screens = if (superpose) 1 else colnames(x),
 ...,
 superpose = FALSE,
 cut = FALSE,
 type = "l",
 col = NULL,
 lty = NULL,
 lwd = NULL,
 pch = NULL,
 cex = NULL,
 fill = NULL,
 auto.key = superpose,
 panel = if (superpose) "panel.superpose"
 else "panel.superpose.plain",
 par.settings = list(),
 layout = NULL, as.table = TRUE,
 xlab = "Time", ylab = NULL,
 default.scales = list(y = list(relation =
 if (missing(cut)) "free" else "same")))
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object of class <code>ts</code> , which may be multi-variate, i.e. have a matrix structure with multiple columns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>data</code>      | not used, and must be left as <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>...</code>       | additional arguments passed to <code>xyplot</code> , which may pass them on to <code>panel.xyplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>screens</code>   | factor (or coerced to factor) whose levels specify which panel each series is to be plotted in. <code>screens = c(1, 2, 1)</code> would plot series 1, 2 and 3 in panels 1, 2 and 1. May also be a named list, see Details below.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>superpose</code> | overlays all series in one panel (via <code>screens = 1</code> ) and uses grouped style settings (from <code>trellis.par.get("superpose.line")</code> , etc). Note that this is just a convenience argument: its only action is to change the default values of other arguments.                                                                                                                                                                                                                                                                                                                                  |
| <code>cut</code>       | defines a cut-and-stack plot. <code>cut</code> can be a list of arguments to the function <code>equal.count</code> , i.e. <code>number</code> (number of intervals to divide into) and <code>overlap</code> (the fraction of overlap between cuts, default 0.5). If <code>cut</code> is numeric this is passed as the <code>number</code> argument.<br><br><code>cut = TRUE</code> tries to choose an appropriate number of cuts (up to a maximum of 6), using <code>banking</code> , and assuming a square plot region. This should have the effect of minimising wasted space when <code>aspect = "xy"</code> . |

|                                                  |                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>type, col, lty, lwd, pch, cex, fill</code> | graphical arguments, which are processed and eventually passed to <code>panel.xyplot</code> . These arguments can also be vectors or (named) lists, see Details for more information.                                                                                                                                               |
| <code>auto.key</code>                            | a logical, or a list describing how to draw a key. See the <code>auto.key</code> entry in <code>xyplot</code> . The default here is to draw lines, not points, and any specified style arguments should show up automatically.                                                                                                      |
| <code>panel</code>                               | the panel function. It is recommended to leave this alone, but one can pass a <code>panel.groups</code> argument which is handled by <code>panel.superpose</code> for each series.                                                                                                                                                  |
| <code>par.settings</code>                        | style settings beyond the standard <code>col, lty, lwd</code> , etc; see <code>trellis.par.set</code> and <code>simpleTheme</code> .                                                                                                                                                                                                |
| <code>layout</code>                              | numeric vector of length 2 specifying number of columns and rows in the plot. The default is to fill columns with up to 6 rows.                                                                                                                                                                                                     |
| <code>as.table</code>                            | to draw panels from top to bottom. The order is determined by the order of columns in <code>x</code> .                                                                                                                                                                                                                              |
| <code>xlab, ylab</code>                          | X axis and Y axis labels; see <code>xyplot</code> . Note in particular that <code>ylab</code> may be a character vector, in which case the labels are spaced out equally, to correspond to the panels; but <i>NOTE</i> in this case the vector should be reversed OR the argument <code>as.table</code> set to <code>FALSE</code> . |
| <code>default.scales</code>                      | scales specification. The default is set to have "free" Y axis scales unless cut is given. Note, users should pass the <code>scales</code> argument rather than <code>default.scales</code> .                                                                                                                                       |

### Details

The handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., `list(A = c(1,2), c(3,4))` in which `c(3, 4)` is the default value and `c(1, 2)` the value only for series A. The `screens` argument can be specified in a similar way.

Some examples are given below.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Author(s)

Gabor Grothendieck, Achim Zeileis, Deepayan Sarkar and Felix Andrews <[felix@nfrac.org](mailto:felix@nfrac.org)>.

The first two authors developed `xyplot.ts` in their **zoo** package, including the `screens` approach. The third author developed a different `xyplot.ts` for cut-and-stack plots in the **latticeExtra** package. The final author fused these together.

### References

Sarkar, Deepayan (2008) *Lattice: Multivariate Data Visualization with R*, Springer. <http://lmdvr.r-forge.r-project.org/> (cut-and-stack plots)

`xyplot`, `panel.xyplot`, `plot.ts`, `ts`, `xyplot.zoo` in the **zoo** package.

## Examples

```
xyplot(ts(c(1:10,10:1)))

Figure 14.1 from Sarkar (2008)
xyplot(sunspot.year, aspect = "xy",
 strip = FALSE, strip.left = TRUE,
 cut = list(number = 4, overlap = 0.05))

A multivariate example; first juxtaposed, then superposed
xyplot(EuStockMarkets, scales = list(y = "same"))
xyplot(EuStockMarkets, superpose = TRUE, aspect = "xy", lwd = 2,
 type = c("l", "g"), ylim = c(0, max(EuStockMarkets)))

Examples using screens (these two are identical)
xyplot(EuStockMarkets, screens = c(rep("Continental", 3), "UK"))
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"))

Automatic group styles
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
 superpose = TRUE)

xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
 superpose = TRUE, xlim = extendrange(1996:1998),
 par.settings = standard.theme(color = FALSE))

Specifying styles for series by name
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
 col = list(DAX = "red", FTSE = "blue", "black"), auto.key = TRUE)

xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
 col = list(DAX = "red"), lty = list(SMI = 2), lwd = 1:2,
 auto.key = TRUE)

Example with simpler data, few data points
set.seed(1)
z <- ts(cbind(a = 1:5, b = 11:15, c = 21:25) + rnorm(5))
xyplot(z, screens = 1)
xyplot(z, screens = list(a = "primary (a)", "other (b & c)"),
 type = list(a = c("p", "h"), b = c("p", "s"), "o"),
 pch = list(a = 2, c = 3), auto.key = list(type = "o"))
```

---

B.02 barchart.table     *table methods for barchart and dotplot*

---

## Description

Contingency tables are often displayed using bar charts and dot plots. These methods operate directly on tables, bypassing the need to convert them to data frames for use with the formula interface. Matrices and arrays are also supported, by coercing them to tables.

## Usage

```
S3 method for class 'table'
barchart(x, data, groups = TRUE,
```

```

 origin = 0, stack = TRUE, ..., horizontal = TRUE)

S3 method for class 'array'
barchart(x, data, ...)

S3 method for class 'matrix'
barchart(x, data, ...)

S3 method for class 'table'
dotplot(x, data, groups = TRUE, ..., horizontal = TRUE)

S3 method for class 'array'
dotplot(x, data, ...)

S3 method for class 'matrix'
dotplot(x, data, ...)

```

### Arguments

|                            |                                                                                                                           |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | A table, array or matrix object.                                                                                          |
| <code>data</code>          | Should not be specified. If specified, will be ignored with a warning.                                                    |
| <code>groups</code>        | A logical flag, indicating whether to use the last dimension as a grouping variable in the display.                       |
| <code>origin, stack</code> | Arguments to <a href="#">panel.barchart</a> . The defaults for the table method are different.                            |
| <code>horizontal</code>    | Logical flag, indicating whether the plot should be horizontal (with the categorical variable on the y-axis) or vertical. |
| <code>...</code>           | Other arguments, passed to the underlying formula method.                                                                 |

### Details

The first dimension is used as the variable on the categorical axis. The last dimension is optionally used as a grouping variable (to produce stacked barcharts by default). All other dimensions are used as conditioning variables. The order of these variables cannot be altered (except by permuting the original argument beforehand using [t](#) or [aperm](#)). For more flexibility, use the formula method after converting the table to a data frame using the relevant [as.data.frame](#) method.

### Value

An object of class "trellis". The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

## Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x       | <p>The object on which method dispatch is carried out.</p> <p>For the formula method, x can be a formula of the form <math>\sim x \mid g1 * g2 * \dots</math>, indicating that histograms or kernel density estimates of the x variable should be produced conditioned on the levels of the (optional) variables g1, g2, .... x should be numeric (or possibly a factor in the case of histogram), and each of g1, g2, ... should be either factors or shingles.</p> <p>As a special case, the right hand side of the formula can contain more than one term separated by '+' signs (e.g., <math>\sim x1 + x2 \mid g1 * g2</math>). What happens in this case is described in the documentation for <a href="#">xyplot</a>. Note that in either form, all the terms in the formula must have the same length after evaluation.</p> <p>For the numeric and factor methods, x is the variable whose histogram or Kernel density estimate is drawn. Conditioning is not allowed in these cases.</p> |
| data    | For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see <a href="#">xyplot</a> for details). data should not be specified for the other methods, and is ignored with a warning if it is.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| formula | The formula to be used for the "data.frame" methods. See documentation for argument x for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| type    | A character string indicating the type of histogram that is to be drawn. "percent" and "count" give relative frequency and frequency histograms re-                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

spectively, and can be misleading when breakpoints are not equally spaced. "density" produces a density histogram.

type defaults to "density" when the breakpoints are unequally spaced, and when breaks is NULL or a function, and to "percent" otherwise.

**nint** An integer specifying the number of histogram bins, applicable only when breaks is unspecified or NULL in the call. Ignored when the variable being plotted is a factor.

**endpoints** A numeric vector of length 2 indicating the range of x-values that is to be covered by the histogram. This applies only when breaks is unspecified and the variable being plotted is not a factor. In `do.breaks`, this specifies the interval that is to be divided up.

**breaks** Usually a numeric vector of length (number of bins + 1) defining the breakpoints of the bins. Note that when breakpoints are not equally spaced, the only value of type that makes sense is density.

When breaks is unspecified, the value of `lattice.getOption("histogram.breaks")` is first checked. If this value is NULL, then the default is to use

```
breaks = seq_len(1 + nlevels(x)) - 0.5
```

when x is a factor, and

```
breaks = do.breaks(endpoints, nint)
```

otherwise. Breakpoints calculated in such a manner are used in all panels. If the retrieved value is not NULL, or if breaks is explicitly specified, it affects the display in each panel independently. Valid values are those accepted as the breaks argument in [hist](#). In particular, this allows specification of breaks as an integer giving the number of bins (similar to nint), as a character string denoting a method, or as a function.

When specified explicitly, a special value of breaks is NULL, in which case the number of bins is determined by nint and then breakpoints are chosen according to the value of `equal.widths`.

**equal.widths** A logical flag, relevant only when breaks=NULL. If TRUE, equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (typically producing unequally spaced breakpoints).

**n** Integer, giving the number of points at which the kernel density is to be evaluated. Passed on as an argument to [density](#).

**panel** A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel functions [panel.histogram](#) and [panel.densityplot](#) are documented separately, and have arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.

**allow.multiple, outer**

See [xyplot](#).

**auto.key** See [xyplot](#).

**aspect** See [xyplot](#).

**prepanel** See [xyplot](#).

**scales** See [xyplot](#).

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <code>subset</code>             | See <a href="#">xyplot</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>default.prepanel</code>   | Fallback prepanel function. See <a href="#">xyplot</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>weights</code>            | numeric vector of weights for the density calculations, evaluated in the non-standard manner used for groups and terms in the formula, if any. If this is specified, it is subsetted using <code>subscripts</code> inside the panel function to match it to the corresponding <code>x</code> values.<br><br>At the time of writing, <code>weights</code> do not work in conjunction with an extended formula specification (this is not too hard to fix, so just bug the maintainer if you need this feature). |
| <code>bw, adjust, width</code>  | Arguments controlling bandwidth. Passed on as arguments to <a href="#">density</a> .                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>kernel, window</code>     | The choice of kernel. Passed on as arguments to <a href="#">density</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>give.Rkern</code>         | Logical flag, passed on as argument to <a href="#">density</a> . This argument is made available only for ease of implementation, and will produce an error if TRUE.                                                                                                                                                                                                                                                                                                                                           |
| <code>from, to, cut</code>      | Controls range over which density is evaluated. Passed on as arguments to <a href="#">density</a> .                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>na.rm</code>              | Logical flag specifying whether NA values should be ignored. Passed on as argument to <a href="#">density</a> , but unlike in <code>density</code> , the default is TRUE.                                                                                                                                                                                                                                                                                                                                      |
| <code>...</code>                | Further arguments. See corresponding entry in <a href="#">xyplot</a> for non-trivial details.                                                                                                                                                                                                                                                                                                                                                                                                                  |

### Details

`histogram` draws Conditional Histograms, and `densityplot` draws Conditional Kernel Density Plots. The default panel function uses the [density](#) function to compute the density estimate, and all arguments accepted by `density` can be specified in the call to `densityplot` to control the output. See documentation of `density` for details.

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

`do.breaks` is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

### Value

An object of class `"trellis"`. The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

**Note**

The form of the arguments accepted by the default panel function `panel.histogram` is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside `histogram` and passes only the breakpoints and the heights to the panel function, **lattice** simply passes along the original variable `x` along with the breakpoints. This approach is more flexible; see the example below with an estimated density superimposed over the histogram.

[xyplot](#), [panel.histogram](#), [density](#), [panel.densityplot](#), [panel.mathdensity](#), [Lattice](#)

**Examples**

```
require(stats)
histogram(~ height | voice.part, data = singer, nint = 17,
 endpoints = c(59.5, 76.5), layout = c(2,4), aspect = 1,
 xlab = "Height (inches)")

histogram(~ height | voice.part, data = singer,
 xlab = "Height (inches)", type = "density",
 panel = function(x, ...) {
 panel.histogram(x, ...)
 panel.mathdensity(dmath = dnorm, col = "black",
 args = list(mean=mean(x),sd=sd(x)))
 })

densityplot(~ height | voice.part, data = singer, layout = c(2, 4),
 xlab = "Height (inches)", bw = 5)
```

**Description**

Draw quantile-Quantile plots of a sample against a theoretical distribution, possibly conditioned on other variables.

**Usage**

```
qqmath(x, data, ...)

S3 method for class 'formula'
qqmath(x,
```

```

data,
allow.multiple = is.null(groups) || outer,
outer = !is.null(groups),
distribution = qnorm,
f.value = NULL,
auto.key = lattice.getOption("default.args")$auto.key,
aspect = "fill",
panel = lattice.getOption("panel.qqmath"),
prepanel = NULL,
scales, strip, groups,
xlab, xlim, ylab, ylim,
drop.unused.levels = lattice.getOption("drop.unused.levels"),
...,
lattice.options = NULL,
default.scales = list(),
default.prepanel = lattice.getOption("prepanel.default.qqmath"),
subscripts,
subset)

S3 method for class 'data.frame'
qqmath(x, data = NULL, formula = data, ...)

S3 method for class 'numeric'
qqmath(x, data = NULL, ylab, ...)

```

### Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x            | <p>The object on which method dispatch is carried out.</p> <p>For the "formula" method, x should be a formula of the form <math>\sim x \mid g1 * g2 * \dots</math>, where x should be a numeric variable. For the "numeric" method, x should be a numeric vector.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| data         | <p>For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see <a href="#">xyplot</a> for details). data should not be specified for the other methods, and is ignored with a warning if it is.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| formula      | <p>The formula to be used for the "data.frame" methods. See documentation for argument x for details.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| distribution | <p>A quantile function that takes a vector of probabilities as argument and produces the corresponding quantiles from a theoretical distribution. Possible values are <a href="#">qnorm</a>, <a href="#">qunif</a>, etc. Distributions with other required arguments need to be provided as user-defined functions (see example with <a href="#">qt</a>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| f.value      | <p>An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function <code>ppoints</code>, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the <a href="#">quantile</a> function for the sample, and the function specified as the distribution argument for the theoretical distribution.</p> <p>f.value defaults to NULL, which has the effect of using <code>ppoints</code> for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for <code>qqnorm</code>, but different from the S-PLUS default of <code>f.value=ppoints</code>.</p> |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    | For large <code>x</code> , this argument can be used to restrict the number of points plotted. See also the <code>tails.n</code> argument in <a href="#">panel.qqmath</a> .                                                                                                                                                                                                        |
| <code>panel</code>                 | A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function <a href="#">panel.qqmath</a> is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function. |
| <code>allow.multiple, outer</code> | See <a href="#">xyplot</a> .                                                                                                                                                                                                                                                                                                                                                       |
| <code>auto.key</code>              | See <a href="#">xyplot</a> .                                                                                                                                                                                                                                                                                                                                                       |

## Details

`qqmath` produces Q-Q plots of the given sample against a theoretical distribution. The default behaviour of `qqmath` is different from the corresponding S-PLUS function, but is similar to `qqnorm`. See the entry for `f.value` for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the `panel` (and `prepanel` function) and not `qqmath` itself. In fact, both the arguments `distribution` and `f.value` are passed unchanged to the `panel` and `prepanel` function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for [panel.qqmath](#) for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for [xyplot](#), which should be consulted to learn more detailed usage.

## Value

An object of class `"trellis"`. The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

**Examples**

```
qqmath(~ rnorm(100), distribution = function(p) qt(p, df = 10))
qqmath(~ height | voice.part, aspect = "xy", data = singer,
 prepanel = prepanel.qqmathline,
 panel = function(x, ...) {
 panel.qqmathline(x, ...)
 panel.qqmath(x, ...)
 })
vp.comb <-
 factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
 "[", 1),
 levels = c("Bass", "Tenor", "Alto", "Soprano"))
vp.group <-
 factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
 "[", 2))
qqmath(~ height | vp.comb, data = singer,
 groups = vp.group, auto.key = list(space = "right"),
 aspect = "xy",
 prepanel = prepanel.qqmathline,
 panel = function(x, ...) {
 panel.qqmathline(x, ...)
 panel.qqmath(x, ...)
 })
```

*Quantile-Quantile Plots of Two Samples*

---

**Description**

Quantile-Quantile plots for comparing two Distributions

**Usage**

```
qq(x, data, ...)

S3 method for class 'formula'
qq(x, data, aspect = "fill",
 panel = lattice.getOption("panel.qq"),
 prepanel, scales, strip,
 groups, xlab, xlim, ylab, ylim, f.value = NULL,
 drop.unused.levels = lattice.getOption("drop.unused.levels"),
 ...,
 lattice.options = NULL,
 qtype = 7,
 default.scales = list(),
```

```

default.prepanel = lattice.getOption("prepanel.default.qq"),
subscripts,
subset)

S3 method for class 'data.frame'
qq(x, data = NULL, formula = data, ...)

```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                  | <p>The object on which method dispatch is carried out.</p> <p>For the "formula" method, x should be a formula of the form <math>y \sim x \mid g1 * g2 * \dots</math>, where x should be a numeric variable, and y a factor, shingle, character, or numeric variable, with the restriction that there must be exactly two levels of y, which divide the values of x into two groups. Quantiles for these groups will be plotted against each other along the two axes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| data               | For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see <a href="#">xyplot</a> for details).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| formula            | The formula to be used for the "data.frame" method. See documentation for argument x for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| f.value            | <p>An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function <code>ppoints</code>, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the quantile function.</p> <p>f.value defaults to NULL, which is equivalent to</p> <pre>f.value = function(n) ppoints(n, a = 1)</pre> <p>This has the effect of including the minimum and maximum data values in the computed quantiles. This is similar to what happens for <code>qqplot</code> but different from the default behaviour of <code>qq</code> in S-PLUS.</p> <p>For large x, this argument can be used to restrict the number of quantiles plotted.</p> |
| panel              | A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function <code>panel.qq</code> is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| qtype              | The type argument for <a href="#">quantile</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

```

lattice.options See xyplot.
default.scales See xyplot.
subscripts See xyplot.
subset See xyplot.
default.prepanel Fallback prepanel function. See xyplot.
... Further arguments. See corresponding entry in xyplot for non-trivial details.

```

### Details

qq produces Q-Q plots of two samples. The default behaviour of qq is different from the corresponding S-PLUS function. See the entry for `f.value` for specifics.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

### Examples

```

qq(voice.part ~ height, aspect = 1, data = singer,
 subset = (voice.part == "Bass 2" | voice.part == "Tenor 1"))

```

### Description

Draws false color level plots and contour plots.

### Usage

```

levelplot(x, data, ...)
contourplot(x, data, ...)

S3 method for class 'formula'
levelplot(x,
 data,
 allow.multiple = is.null(groups) || outer,

```

```

outer = TRUE,
aspect = "fill",
panel = if (useRaster) lattice.getOption("panel.levelplot.raster")
 else lattice.getOption("panel.levelplot"),
prepanel = NULL,
scales = list(),
strip = TRUE,
groups = NULL,
xlab,
xlim,
ylab,

region = TRUE,
drop.unused.levels =
 lattice.getOption("drop.unused.levels"),
...,
useRaster = FALSE,
lattice.options = NULL,
default.scales = list(),
default.prepanel =
 lattice.getOption("prepanel.default.levelplot"),
colorkey = region,
col.regions,
alpha.regions,
subset = TRUE)

S3 method for class 'formula'
contourplot(x,
 data,
 panel = lattice.getOption("panel.contourplot"),
 default.prepanel =
 lattice.getOption("prepanel.default.contourplot"),
 cuts = 7,
 labels = TRUE,
 contour = TRUE,
 pretty = TRUE,
 region = FALSE,
 ...)

S3 method for class 'data.frame'
levelplot(x, data = NULL, formula = data, ...)

S3 method for class 'data.frame'
contourplot(x, data = NULL, formula = data, ...)

S3 method for class 'table'
levelplot(x, data = NULL, aspect = "iso", ..., xlim, ylim)

S3 method for class 'table'

```

```

contourplot(x, data = NULL, aspect = "iso", ..., xlim, ylim)

S3 method for class 'matrix'
levelplot(x, data = NULL, aspect = "iso",
 ..., xlim, ylim,
 row.values = seq_len(nrow(x)),
 column.values = seq_len(ncol(x)))

S3 method for class 'matrix'
contourplot(x, data = NULL, aspect = "iso",
 ..., xlim, ylim,
 row.values = seq_len(nrow(x)),
 column.values = seq_len(ncol(x)))

S3 method for class 'array'
levelplot(x, data = NULL, ...)

S3 method for class 'array'
contourplot(x, data = NULL, ...)

```

## Arguments

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                         | <p>for the formula method, a formula of the form <math>z \sim x * y \mid g1 * g2 * \dots</math>, where <math>z</math> is a numeric response, and <math>x, y</math> are numeric values evaluated on a rectangular grid. <math>g1, g2, \dots</math> are optional conditional variables, and must be either factors or shingles if present.</p> <p>Calculations are based on the assumption that all <math>x</math> and <math>y</math> values are evaluated on a grid (defined by their unique values). The function will not return an error if this is not true, but the display might not be meaningful. However, the <math>x</math> and <math>y</math> values need not be equally spaced.</p> <p>Both <code>levelplot</code> and <code>wireframe</code> have methods for <code>matrix</code>, <code>array</code>, and <code>table</code> objects, in which case <math>x</math> provides the <math>z</math> vector described above, while its rows and columns are interpreted as the <math>x</math> and <math>y</math> vectors respectively. This is similar to the form used in <code>filled.contour</code> and <code>image</code>. For higher-dimensional arrays and tables, further dimensions are used as conditioning variables. Note that the <code>dimnames</code> may be duplicated; this is handled by calling <code>make.unique</code> to make the names unique (although the original labels are used for the <math>x</math>- and <math>y</math>-axes).</p> |
| <code>data</code>                      | For the formula methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. Usually ignored with a warning in other cases.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>formula</code>                   | The formula to be used for the "data.frame" methods. See documentation for argument <code>x</code> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>row.values, column.values</code> | Optional vectors of values that define the grid when $x$ is a matrix. <code>row.values</code> and <code>column.values</code> must have the same lengths as <code>nrow(x)</code> and <code>ncol(x)</code> respectively. By default, row and column numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>panel</code>                     | <code>panel</code> function used to create the display, as described in <a href="#">xyplot</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>aspect</code>                    | For the <code>matrix</code> methods, the default aspect ratio is chosen to make each cell square. The usual default is <code>aspect="fill"</code> , as described in <a href="#">xyplot</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| at            | <p>A numeric vector giving breakpoints along the range of <code>z</code>. Contours (if any) will be drawn at these heights, and the regions in between would be colored using <code>col.regions</code>. In the latter case, values outside the range of <code>at</code> will not be drawn at all. This serves as a way to limit the range of the data shown, similar to what a <code>zlim</code> argument might have been used for. However, this also means that when supplying <code>at</code> explicitly, one has to be careful to include values outside the range of <code>z</code> to ensure that all the data are shown.</p> <p><code>at</code> can have length one only if <code>region=FALSE</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| col.regions   | <p>color vector to be used if <code>regions</code> is <code>TRUE</code>. The general idea is that this should be a color vector of moderately large length (longer than the number of regions. By default this is 100). It is expected that this vector would be gradually varying in color (so that nearby colors would be similar). When the colors are actually chosen, they are chosen to be equally spaced along this vector. When there are more regions than colors in <code>col.regions</code>, the colors are recycled. The actual color assignment is performed by <a href="#">level.colors</a>, which is documented separately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| alpha.regions | <p>Numeric, specifying alpha transparency (works only on some devices)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| colorkey      | <p>A logical flag specifying whether a colorkey is to be drawn alongside the plot, or a list describing the colorkey. The list may contain the following components:</p> <p><b>space:</b> location of the colorkey, can be one of "left", "right", "top" and "bottom". Defaults to "right".</p> <p><b>x, y:</b> location, currently unused</p> <p><b>col:</b> A color ramp specification, as in the <code>col.regions</code> argument in <a href="#">level.colors</a></p> <p><b>at:</b> A numeric vector specifying where the colors change. must be of length 1 more than the <code>col</code> vector.</p> <p><b>tri.lower, tri.upper:</b> Logical or numeric controlling whether the first and last intervals should be triangular instead of rectangular. With the default value (NA), this happens only if the corresponding extreme <code>at</code> values are <code>-Inf</code> or <code>Inf</code> respectively, and the triangles occupy 5% of the total length of the color key. If numeric and between 0 and 0.25, these give the corresponding fraction, which is again 5% when specified as <code>TRUE</code>.</p> <p><b>labels:</b> A character vector for labelling the <code>at</code> values, or more commonly, a list describing characteristics of the labels. This list may include components <code>labels</code>, <code>at</code>, <code>cex</code>, <code>col</code>, <code>rot</code>, <code>font</code>, <code>fontface</code> and <code>fontfamily</code>.</p> <p><b>title:</b> Usually a character vector or expression providing a title for the colorkey, or a list controlling the title in further detail, or an arbitrary "grob". For details of how the list form is interpreted, see the entry for <code>main</code> in <a href="#">xyplot</a>; generally speaking, the actual label should be specified as the <code>label</code> component (which may be unnamed if it is the first component), and the remaining arguments are used as appropriate in a call to <a href="#">textGrob</a>. Further control of the placement of the title is possible through the component <code>title.control</code>. In particular, if a <code>rot</code> component is not specified, its default depends on the value of <code>title.control\$side</code> (0 for top or bottom, and 90 for left or right).</p> <p><code>title</code> defaults to <code>NULL</code>, which means no title is drawn.</p> <p><b>title.control:</b> A list providing control over the placement of a title, if specified. Currently two components are honoured: <code>side</code> can take values "top", "bottom", "left", and "right", and specifies the side of the colorkey on which the title is to be placed. Defaults to the value of the "space" component. <code>padding</code> is a multiplier for the default amount of padding between the title and the colorkey.</p> |

|                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <code>...</code>                                                                                                                                                                                                                                                                                                                               | Further arguments may be supplied. Some are processed by <code>levelplot</code> or <code>contourplot</code> , and those that are unrecognized are passed on to the panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>useRaster</code>                                                                                                                                                                                                                                                                                                                         | <p>A logical flag indicating whether raster representations should be used, both for the false color image and the color key (if present). Effectively, setting this to <code>TRUE</code> changes the default panel function from <a href="#">panel.levelplot</a> to <a href="#">panel.levelplot.raster</a>, and sets the default value of <code>colorkey\$raster</code> to <code>TRUE</code>.</p> <p>Note that <a href="#">panel.levelplot.raster</a> provides only a subset of the features of <a href="#">panel.levelplot</a>, but setting <code>useRaster=TRUE</code> will not check whether any of the additional features have been requested.</p> <p>Not all devices support raster images. For devices that appear to lack support, <code>useRaster=TRUE</code> will be ignored with a warning.</p>                                                                                                                                                                                                                                               |

## Details

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Other useful arguments are mentioned in the help page for the default panel function [panel.levelplot](#) (these are formally arguments to the panel function, but can be specified in the high level calls directly).

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**Examples**

```
x <- seq(pi/4, 5 * pi, length.out = 100)
y <- seq(pi/4, 5 * pi, length.out = 100)
r <- as.vector(sqrt(outer(x^2, y^2, "+")))
grid <- expand.grid(x=x, y=y)
grid$z <- cos(r^2) * exp(-r/(pi^3))
levelplot(z ~ x * y, grid, cuts = 50, scales=list(log="e"), xlab="",
 ylab="", main="Weird Function", sub="with log scales",
 colorkey = FALSE, region = TRUE)
triangular end-points in color key, with a title
levelplot(z ~ x * y, grid, col.regions = hcl.colors(10),
 at = c(-Inf, seq(-0.8, 0.8, by = 0.2), Inf))

#S-PLUS example
require(stats)
attach(environmental)
ozo.m <- loess((ozone^(1/3)) ~ wind * temperature * radiation,
 parametric = c("radiation", "wind"), span = 1, degree = 2)
w.marginal <- seq(min(wind), max(wind), length.out = 50)
t.marginal <- seq(min(temperature), max(temperature), length.out = 50)
r.marginal <- seq(min(radiation), max(radiation), length.out = 4)
wtr.marginal <- list(wind = w.marginal, temperature = t.marginal,
 radiation = r.marginal)
grid <- expand.grid(wtr.marginal)
grid[, "fit"] <- c(predict(ozo.m, grid))
contourplot(fit ~ wind * temperature | radiation, data = grid,
 cuts = 10, region = TRUE,
 xlab = "Wind Speed (mph)",
 ylab = "Temperature (F)",
 main = "Cube Root Ozone (cube root ppb)")
detach()
```

## Description

Generic functions to draw 3d scatter plots and surfaces. The "formula" methods do most of the actual work.

## Usage

```
cloud(x, data, ...)
wireframe(x, data, ...)

S3 method for class 'formula'
cloud(x,
 data,
 allow.multiple = is.null(groups) || outer,
 outer = FALSE,
 auto.key = lattice.getOption("default.args")$auto.key,
 aspect = c(1,1),
 panel.aspect = 1,
 panel = lattice.getOption("panel.cloud"),
 prepanel = NULL,
 scales = list(),
 strip = TRUE,
 groups = NULL,
 xlab,
 ylab,
 zlab,
 xlim = if (is.factor(x)) levels(x) else range(x, finite = TRUE),
 ylim = if (is.factor(y)) levels(y) else range(y, finite = TRUE),
 zlim = if (is.factor(z)) levels(z) else range(z, finite = TRUE),
 at,
 drape = FALSE,
 pretty = FALSE,
 drop.unused.levels,
 ...,
 lattice.options = NULL,
 default.scales =
 list(distance = c(1, 1, 1),
 arrows = TRUE,
 axs = axs.default),
 default.prepanel = lattice.getOption("prepanel.default.cloud"),
 colorkey,
 col.regions,
 alpha.regions,
 cuts = 70,
 subset = TRUE,
 axs.default = "r")

S3 method for class 'data.frame'
```

```

cloud(x, data = NULL, formula = data, ...)

S3 method for class 'formula'
wireframe(x,
 data,
 panel = lattice.getOption("panel.wireframe"),
 default.prepanel = lattice.getOption("prepanel.default.wireframe"),
 ...)

S3 method for class 'data.frame'
wireframe(x, data = NULL, formula = data, ...)

S3 method for class 'matrix'
cloud(x, data = NULL, type = "h",
 zlab = deparse(substitute(x)), aspect, ...,
 xlim, ylim, row.values, column.values)

S3 method for class 'table'
cloud(x, data = NULL, groups = FALSE,
 zlab = deparse(substitute(x)),
 type = "h", ...)

S3 method for class 'matrix'
wireframe(x, data = NULL,
 zlab = deparse(substitute(x)), aspect, ...,
 xlim, ylim, row.values, column.values)

```

## Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x       | <p>The object on which method dispatch is carried out.</p> <p>For the "formula" methods, a formula of the form <math>z \sim x * y \mid g1 * g2 * \dots</math>, where <math>z</math> is a numeric response, and <math>x, y</math> are numeric values. <math>g1, g2, \dots</math>, if present, are conditioning variables used for conditioning, and must be either factors or shingles. In the case of <code>wireframe</code>, calculations are based on the assumption that the <math>x</math> and <math>y</math> values are evaluated on a rectangular grid defined by their unique values. The grid points need not be equally spaced.</p> <p>For <code>wireframe</code>, <math>x, y</math> and <math>z</math> may also be matrices (of the same dimension), in which case they are taken to represent a 3-D surface parametrized on a 2-D grid (e.g., a sphere). Conditioning is not possible with this feature. See details below.</p> <p>Missing values are allowed, either as NA values in the <math>z</math> vector, or missing rows in the data frame (note however that in that case the <math>X</math> and <math>Y</math> grids will be determined only by the available values). For a grouped display (producing multiple surfaces), missing rows are not allowed, but NA-s in <math>z</math> are.</p> <p>Both <code>wireframe</code> and <code>cloud</code> have methods for matrix objects, in which case <math>x</math> provides the <math>z</math> vector described above, while its rows and columns are interpreted as the <math>x</math> and <math>y</math> vectors respectively. This is similar to the form used in <code>persp</code>.</p> |
| data    | <p>For the "formula" methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. <code>data</code> should not be specified except when using the "formula" method.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| formula | <p>The formula to be used for the "data.frame" methods. See documentation for argument <code>x</code> for details.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <code>row.values</code> , <code>column.values</code>                                                                                                                                                                                                                                                                                             | Optional vectors of values that define the grid when <code>x</code> is a matrix. <code>row.values</code> and <code>column.values</code> must have the same lengths as <code>nrow(x)</code> and <code>ncol(x)</code> respectively. By default, row and column numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>allow.multiple</code> , <code>outer</code> , <code>auto.key</code> , <code>prepanel</code> , <code>strip</code> , <code>groups</code> , <code>xlab</code> , <code>xlim</code> , <code>ylab</code> , <code>ylim</code> , <code>drop.unused.levels</code> , <code>lattice.options</code> , <code>default.scales</code> , <code>subset</code> | These arguments are documented in the help page for <a href="#">xyplot</a> . For the <code>cloud.table</code> method, <code>groups</code> must be a logical indicating whether the last dimension should be used as a grouping variable as opposed to a conditioning variable. This is only relevant if the table has more than 2 dimensions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>type</code>                                                                                                                                                                                                                                                                                                                                | type of display in <code>cloud</code> (see <a href="#">panel.3dscatter</a> for details). Defaults to "h" for the <code>matrix</code> method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>aspect</code> , <code>panel.aspect</code>                                                                                                                                                                                                                                                                                                  | <p>Unlike other high level functions, <code>aspect</code> is taken to be a numeric vector of length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the enclosing cube. The usual role of the <code>aspect</code> argument in determining the aspect ratio of the panel (see <a href="#">xyplot</a> for details) is played by <code>panel.aspect</code>, except that it can only be a numeric value.</p> <p>For the <code>matrix</code> methods, the default y/x aspect is <code>ncol(x) / nrow(x)</code> and the z/x aspect is the smaller of the y/x aspect and 1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>panel</code>                                                                                                                                                                                                                                                                                                                               | panel function used to create the display. See <a href="#">panel.cloud</a> for (non-trivial) details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>default.prepanel</code>                                                                                                                                                                                                                                                                                                                    | Fallback <code>prepanel</code> function. See <a href="#">xyplot</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>scales</code>                                                                                                                                                                                                                                                                                                                              | <p>a list describing the scales. As with other high level functions (see <a href="#">xyplot</a> for details), this list can contain parameters in <code>name=value</code> form. It can also contain components with the special names <code>x</code>, <code>y</code> and <code>z</code>, which can be similar lists with axis-specific values overriding the ones specified in <code>scales</code>.</p> <p>The most common use for this argument is to set <code>arrows=FALSE</code>, which causes tick marks and labels to be used instead of arrows being drawn (the default). Both can be suppressed by <code>draw=FALSE</code>. Another special component is <code>distance</code>, which specifies the relative distance of the axis label from the bounding box. If specified as a component of <code>scales</code> (as opposed to one of <code>scales\$z</code> etc), this can be (and is recycled if not) a vector of length 3, specifying distances for the <code>x</code>, <code>y</code> and <code>z</code> labels respectively.</p> <p>Other components that work in the <code>scales</code> argument of <code>xyplot</code> etc. should also work here (as long as they make sense), including explicit specification of tick mark locations and labels. (Not everything is implemented yet, but if you find something that should work but does not, feel free to bug the maintainer.)</p> <p>Note, however, that for these functions <code>scales</code> cannot contain information that is specific to particular panels. If you really need that, consider using the <code>scales.3d</code> argument of <code>panel.cloud</code>.</p> |
| <code>axis.default</code>                                                                                                                                                                                                                                                                                                                        | Unlike 2-D display functions, <code>cloud</code> does not expand the bounding box to slightly beyond the range of the data, even though it should. This is primarily because this is the natural behaviour in <code>wireframe</code> , which uses the same code. <code>axis.default</code> is intended to provide a different default for <code>cloud</code> . However, this feature has not yet been implemented.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>zlab</code>                                                                                                                                                                                                                                                                                                                                | Specifies a label describing the <code>z</code> variable in ways similar to <code>xlab</code> and <code>ylab</code> (i.e. "grob", character string, expression or list) in other high level functions. Additionally, if <code>zlab</code> (and <code>xlab</code> and <code>ylab</code> ) is a list, it can contain a component called <code>rot</code> , controlling the rotation for the label                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>zlim</code>                                                       | limits for the z-axis. Similar to <code>xlim</code> and <code>ylim</code> in other high level functions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>drape</code>                                                      | logical, whether the wireframe is to be draped in color. If TRUE, the height of a facet is used to determine its color in a manner similar to the coloring scheme used in <a href="#">levelplot</a> . Otherwise, the background color is used to color the facets. This argument is ignored if <code>shade = TRUE</code> (see <a href="#">panel.3dwire</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>at</code> , <code>col.regions</code> , <code>alpha.regions</code> | these arguments are analogous to those in <a href="#">levelplot</a> . if <code>drape=TRUE</code> , <code>at</code> gives the vector of cutpoints where the colors change, and <code>col.regions</code> the vector of colors to be used in that case. <code>alpha.regions</code> determines the alpha-transparency on supporting devices. These are passed down to the panel function, and also used in the colorkey if appropriate. The default for <code>col.regions</code> and <code>alpha.regions</code> is derived from the Trellis setting "regions"                                                                                                                                                                                                                                                         |
| <code>cuts</code>                                                       | if <code>at</code> is unspecified, the approximate number of cutpoints if <code>drape=TRUE</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>pretty</code>                                                     | whether automatic choice of cutpoints should be prettfied                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>colorkey</code>                                                   | logical indicating whether a color key should be drawn alongside, or a list describing such a key. See <a href="#">levelplot</a> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>...</code>                                                        | Any number of other arguments can be specified, and are passed to the panel function. In particular, the arguments <code>distance</code> , <code>perspective</code> , <code>screen</code> and <code>R.mat</code> are very important in determining the 3-D display. The argument <code>shade</code> can be useful for wireframe calls, and controls shading of the rendered surface. These arguments are described in detail in the help page for <a href="#">panel.cloud</a> .<br>Additionally, an argument called <code>zoom</code> may be specified, which should be a numeric scalar to be interpreted as a scale factor by which the projection is magnified. This can be useful to get the variable names into the plot. This argument is actually only used by the default <code>prepanel</code> function. |

## Details

These functions produce three dimensional plots in each panel (as long as the default panel functions are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box that is contained in the  $[-0.5, 0.5]$  cube (even smaller for non-default values of aspect). The viewing direction is given by a sequence of rotations specified by the `screen` argument, starting from the positive Z-axis. The viewing point (camera) is located at a distance of  $1/\text{distance}$  from the origin. If `perspective=FALSE`, `distance` is set to 0 (i.e., the viewing point is at an infinite distance).

`cloud` draws a 3-D Scatter Plot, while `wireframe` draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by `wireframe` using the `groups` argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying groups with `cloud` results in a `panel.superpose`-like effect (via [panel.3dscatter](#)).

`wireframe` can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for [panel.3dwire](#). Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to `cloud` and `wireframe` directly.

For single panel plots, `wireframe` can also plot parametrized 3-D surfaces (i.e., functions of the form  $f(u,v) = (x(u,v), y(u,v), z(u,v))$ , where values of  $(u,v)$  lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved by calling `wireframe` with a formula `x` of the form `z~x*y`, where `x`, `y` and `z` are all matrices of the same dimension, representing the values of  $x(u,v)$ ,  $y(u,v)$  and  $z(u,v)$  evaluated on a discrete rectangular grid (the actual values of  $(u,v)$  are irrelevant).

When this feature is used, the heights used to calculate drape colors or shading colors are no longer the `z` values, but the distances of  $(x, y, z)$  from the origin.

Note that this feature does not work with groups, subscripts, subset, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are ‘behind’ the points doesn’t work in some extreme situations. Also, `panel.cloud` tries to figure out the optimal location of the arrows and axis labels automatically, but can fail on occasion (especially when the view is from ‘below’ the data). This can be manually controlled by the `scpos` argument in `panel.cloud`.

These and all other high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Note

There is a known problem with grouped wireframe displays when the (x, y) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the groups argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an NA response (z) in rows that were previously missing.

### Examples

```
volcano ## 87 x 61 matrix
wireframe(volcano, shade = TRUE,
 aspect = c(61/87, 0.4),
 light.source = c(10,0,10))

g <- expand.grid(x = 1:10, y = 5:15, gr = 1:2)
g$z <- log((g$x^g$gr + g$y^2) * g$gr)
wireframe(z ~ x * y, data = g, groups = gr,
 scales = list(arrows = FALSE),
 drape = TRUE, colorkey = TRUE,
 screen = list(z = 30, x = -60))

cloud(Sepal.Length ~ Petal.Length * Petal.Width | Species, data = iris,
 screen = list(x = -90, y = 70), distance = .4, zoom = .6)
```

```

cloud.table

cloud(prop.table(Titanic, margin = 1:3),
 type = c("p", "h"), strip = strip.custom(strip.names = TRUE),
 scales = list(arrows = FALSE, distance = 2), panel.aspect = 0.7,
 zlab = "Proportion")[, 1]

transparent axes

par.set <-
 list(axis.line = list(col = "transparent"),
 clip = list(panel = "off"))
print(cloud(Sepal.Length ~ Petal.Length * Petal.Width,
 data = iris, cex = .8,
 groups = Species,
 main = "Stereo",
 screen = list(z = 20, x = -70, y = 3),
 par.settings = par.set,
 scales = list(col = "black")),
 split = c(1,1,2,1), more = TRUE)
print(cloud(Sepal.Length ~ Petal.Length * Petal.Width,
 data = iris, cex = .8,
 groups = Species,
 main = "Stereo",
 screen = list(z = 20, x = -70, y = 0),
 par.settings = par.set,
 scales = list(col = "black")),
 split = c(2,1,2,1))

```

## Description

Draw Conditional Scatter Plot Matrices and Parallel Coordinate Plots

## Usage

```

splom(x, data, ...)
parallelplot(x, data, ...)

S3 method for class 'formula'
splom(x,
 data,
 auto.key = lattice.getOption("default.args")$auto.key,
 aspect = 1,
 between = list(x = 0.5, y = 0.5),
 panel = lattice.getOption("panel.splom"),

| <code>between</code>                                                                                                                        | to avoid confusion between panels and subpanels, the default is to show the panels of a <i>splo</i> m plot with space between them.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>panel</code>                                                                                                                          | For <i>parallelplot</i> , this has the usual interpretation, i.e., a function that creates the display within each panel.<br>For <i>splo</i> m, the terminology is slightly complicated. The role played by the panel function in most other high-level functions is played here by the <i>superpanel</i> function, which is responsible for the display for each conditional data subset. <code>panel</code> is simply an argument to the default <i>superpanel</i> function <code>panel.pairs</code> , and is passed on to it unchanged. It is used there to create each pairwise display. See <a href="#">panel.pairs</a> for more useful options. |
| <code>superpanel</code>                                                                                                                     | function that sets up the <i>splo</i> m display, by default as a scatterplot matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>pscales</code>                                                                                                                        | a numeric value or a list, meant to be a less functional substitute for the <code>scales</code> argument in <i>xyplot</i> etc. This argument is passed to the <i>superpanel</i> function, and is handled by the default <i>superpanel</i> function <code>panel.pairs</code> . The help page for the latter documents this argument in more detail.                                                                                                                                                                                                                                                                                                    |
| <code>varnames</code>                                                                                                                       | A character or expression vector or giving names to be used for the variables in <code>x</code> . By default, the column names of <code>x</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>horizontal.axis</code>                                                                                                                | logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

See corresponding entry in <a href="#">xyplot</a> for non-trivial details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Details

*splo*m produces Scatter Plot Matrices. The role usually played by `panel` is taken over by *superpanel*, which takes a data frame subset and is responsible for plotting it. It is called with the coordinate system set up to have both `x`- and `y`-limits from `0.5` to `ncol(z) + 0.5`. The only built-in option currently available is [panel.pairs](#), which calls a further panel function for each pair `(i, j)` of variables in `z` inside a rectangle of unit width and height centered at `c(i, j)` (see [panel.pairs](#) for details).

Many of the finer customizations usually done via arguments to high level function like *xyplot* are instead done by `panel.pairs` for *splo*m. These include control of axis limits, tick locations and *prepanel* calculations. If you are trying to fine-tune your *splo*m plot, definitely look at the [panel.pairs](#) help page. The `scales` argument is usually not very useful in *splo*m, and trying to change it may have undesired effects.

[parallelplot](#) draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for *xyplot*, which should be consulted to learn more detailed usage.

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

`xyplot`, `Lattice`, `panel.pairs`, `panel.parallel`.

**Examples**

```
super.sym <- trellis.par.get("superpose.symbol")
splom(~iris[1:4], groups = Species, data = iris,
 panel = panel.superpose,
 key = list(title = "Three Varieties of Iris",
 columns = 3,
 points = list(pch = super.sym$pch[1:3],
 col = super.sym$col[1:3]),
 text = list(c("Setosa", "Versicolor", "Virginica"))))
splom(~iris[1:3]|Species, data = iris,
 layout=c(2,2), pscales = 0,
 varnames = c("Sepal\nLength", "Sepal\nWidth", "Petal\nLength"),
 page = function(...) {
 ltext(x = seq(.6, .8, length.out = 4),
 y = seq(.9, .6, length.out = 4),
 labels = c("Three", "Varieties", "of", "Iris"),
 cex = 2)
 })
parallelplot(~iris[1:4] | Species, iris)
parallelplot(~iris[1:4], iris, groups = Species,
 horizontal.axis = FALSE, scales = list(x = list(rot = 90)))
```

**Description**

`tmd` Creates Tukey Mean-Difference Plots from a trellis object returned by `xyplot`, `qq` or `qqmath`. The `prepanel` and `panel` functions are used as appropriate. The `formula` and `data.frame` methods for `tmd` are provided for convenience, and simply call `tmd` on the object created by the corresponding `xyplot` methods.

**Usage**

```
tmd(object, ...)

S3 method for class 'trellis'
tmd(object,
 xlab = "mean",
 ylab = "difference",
```

```

 panel,
 prepanel,
 ...)

prepanel.tmd.qqmath(x,
 f.value = NULL,
 distribution = qnorm,
 qtype = 7,
 groups = NULL,
 subscripts, ...)
panel.tmd.qqmath(x,
 f.value = NULL,
 distribution = qnorm,
 qtype = 7,
 groups = NULL,
 subscripts, ...,
 identifier = "tmd")
panel.tmd.default(x, y, groups = NULL, ...,
 identifier = "tmd")
prepanel.tmd.default(x, y, ...)

```

### Arguments

|                              |                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| object                       | An object of class "trellis" returned by xyplot, qq or qqmath.                                      |
| xlab                         | x label                                                                                             |
| ylab                         | y label                                                                                             |
| panel                        | panel function to be used. See details below.                                                       |
| prepanel                     | prepanel function. See details below.                                                               |
| f.value, distribution, qtype | see <a href="#">panel.qqmath</a> .                                                                  |
| groups, subscripts           | see <a href="#">xyplot</a> .                                                                        |
| x, y                         | data as passed to panel functions in original call.                                                 |
| ...                          | other arguments                                                                                     |
| identifier                   | A character string that is prepended to the names of grobs that are created by this panel function. |

### Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows: the new coordinates are given by  $x=(x+y)/2$  and  $y=y-x$ , which are then plotted. The default panel function(s) add a reference line at  $y=0$  as well.

tmd acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. tmd uses these panel arguments to set up its own scales (using its prepanel argument) and display (using panel). It is thus important to provide suitable prepanel and panel functions to tmd depending on the original call.

Such functions currently exist for xyplot, qq (the ones with default in their name) and qqmath, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the prepanel and panel arguments default to suitable choices.

tmd uses the update method for "trellis" objects, which processes all extra arguments supplied to tmd.

### Value

An object of class "trellis". The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

tmd(qqmath(~height | voice.part, data = singer))
```

---

B.10 rfs

*Residual and Fit Spread Plots*

---

### Description

Plots fitted values and residuals (via qqmath) on a common scale for any object that has methods for fitted values and residuals.

### Usage

```
rfs(model, layout=c(2, 1), xlab="f-value", ylab=NULL,
 distribution = qunif,
 panel, prepanel, strip, ...)
```

### Arguments

|                              |                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| model                        | a fitted model object with methods fitted.values and residuals. Can be the value returned by oneway |
| layout                       | default layout is c(2,1)                                                                            |
| xlab                         | defaults to "f.value"                                                                               |
| distribution                 | the distribution function to be used for qqmath                                                     |
| ylab, panel, prepanel, strip | See <a href="#">xyplot</a>                                                                          |
| ...                          | other arguments, passed on to <a href="#">qqmath</a> .                                              |

### Value

An object of class "trellis". The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

B.11 oneway

*Fit One-way Model*

---

**Description**

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using `rfs`

**Usage**

```
oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))
```

**Arguments**

|                       |                                                                                                                                                 |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>  | formula of the form $y \sim x$ where $y$ is the numeric response and $x$ is the grouping factor                                                 |
| <code>data</code>     | data frame in which the model is to be evaluated                                                                                                |
| <code>location</code> | function or numeric giving the location statistic to be used for centering the observations, e.g. <code>median</code> , 0 (to avoid centering). |
| <code>spread</code>   | function or numeric giving the spread statistic to be used for scaling the observations, e.g. <code>sd</code> , 1 (to avoid scaling).           |

**Value**

A list with components

`location` vector of locations for each group.

`spread` vector of spreads for each group.

`fitted.values` vector of locations for each observation.

`residuals` residuals ( $y - \text{fitted.values}$ ).

`scaled.residuals` residuals scaled by `spread` for their group

|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| device | function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how R was compiled (see <a href="#">Devices</a> ), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| color  | logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using theme or subsequent calls to <a href="#">trellis.par.set</a> (and by arguments supplied directly in high level calls for some settings).                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| theme  | list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters. A possible use of this argument is to change the default settings by specifying <code>lattice.options(default.theme = "col.whitebg")</code> . For back-compatibility, this is initially (when lattice is loaded) set to <code>getOption(lattice.theme)</code> .<br>If theme is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use <code>.Device</code> inside the function to ascertain what device has been opened. |
| new    | logical flag indicating whether a new device should be started. If FALSE, the options for the current device are changed to the defaults determined by the other arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| retain | logical. If TRUE and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| name   | name of the device for which the setting is required, as returned by <code>.Device</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ...    | additional parameters to be passed to the device function, most commonly file for non-screen devices, as well as height, width, etc. See the help file for individual devices for admissible arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Details**

The `trellis.device` function sets up an R graphics device for use with lattice graphics, by opening the device if necessary, and defining a set of associated graphical parameters (colors, line types, fonts, etc.).

Even if a device is opened without calling `trellis.device`, for example, by calling a device function directly, `trellis.device` is still called automatically when a "trellis" object is plotted. The default graphical settings used in this case can be customized using [lattice.options](#). It is therefore rarely necessary for the user to call `trellis.device` explicitly.

**Value**

None; `trellis.device` is called for the side effect of opening a device and / or setting associated graphical parameters.

**Note**

Earlier versions of `trellis.device` had a `bg` argument to set the background color, but this is no longer supported. If supplied, the `bg` argument will be passed on to the device function; however, this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the `theme` argument instead.

---

C.02a `standard.theme`    *Built-in Graphical Themes*

---

**Description**

Built-in graphical parameter settings. These mainly differ in their choice of colors.

**Usage**

```

standard.theme(name, color = TRUE,
 symbol = palette.colors(palette = "Okabe-Ito")[c(6, 2, 4, 7, 3, 5, 8)],
 fill = NULL,
 region = hcl.colors(14, palette = "YlGnBu", rev = TRUE),
 reference = "gray90",
 bg = "transparent",
 fg = "black",
 ...)
canonical.theme(...)
custom_theme(symbol, fill, region,
 reference = "gray90", bg = "transparent", fg = "black",
 strip.bg = rep("gray95", 7), strip.fg = rep("gray70", 7),
 ...)
classic.theme(name, color)
col.whitebg()

```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name      | character string giving the name of the device for which the setting is required, as returned by <code>.Device</code> . This is only used by <code>classic.theme</code> to allow device-specific setting. It is retained in <code>standard.theme</code> for back-compatibility, but its use is not recommended.              |
| color     | logical, whether the initial settings should be color or black and white.                                                                                                                                                                                                                                                    |
| symbol    | vector of colors to be used for symbols and lines.                                                                                                                                                                                                                                                                           |
| fill      | vector of colors to be used as fill colors, e.g., in bar charts and histograms. The default of <code>NULL</code> in <code>standard.theme</code> results in lightened versions of the symbol colors to be used.                                                                                                               |
| region    | vector of colors to be used to create a color ramp, typically used by <a href="#">levelplot</a>                                                                                                                                                                                                                              |
| reference | color, to be used for reference lines.                                                                                                                                                                                                                                                                                       |
| fg        | color, to be used for foreground elements such as axes and labels.                                                                                                                                                                                                                                                           |
| bg        | color, to be used as background.                                                                                                                                                                                                                                                                                             |
| strip.bg  | color, to be used as strip background.                                                                                                                                                                                                                                                                                       |
| strip.fg  | color, to be used as strip foreground.                                                                                                                                                                                                                                                                                       |
| ...       | additional arguments, passed on to other functions as appropriate. In particular, additional arguments provided to <code>standard.theme</code> will be passed on to <code>custom_theme</code> , and these may include non-color parameters that will be used to modify the resulting theme via <a href="#">simpleTheme</a> . |

**Details**

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable “settings” list (see [trellis.par.set](#) for details). This functionality is analogous to [par](#) for standard R graphics and, together with [lattice.options](#), mostly supplants it ([par](#) settings are mostly ignored by Lattice). Unlike [par](#), Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device).

The functions documented in this page produce such graphical settings (a.k.a. themes), usually to be used with `trellis.device` or `trellis.par.set`.

`classic.theme` and `col.whitebg` produce predefined themes that are not recommended for routine use but are retained for compatibility.

The `classic.theme` function was intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) and was used to obtain defaults prior to R 2.3.0. However, these settings are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, common device-agnostic defaults were used for all devices from R 2.3.0 onwards.

Since R 4.3.0, a new set of defaults given by `standard.theme` is used. The defaults are based on HCL palettes, but customization of the palettes is allowed. Earlier behaviour can be reinstated by setting `classic.theme` as the default theme argument, e.g., by putting `lattice.options(default.theme = classic.theme("pdf"))` in a startup script (see the entry for theme in `trellis.device` for details).

`custom_theme` is the workhorse function called by `standard.theme`. `canonical.theme` is an alias for `standard.theme`.

## Value

A list of components defining graphical parameter settings for Lattice displays. It is used internally in `trellis.device`, and can also be used as the theme argument to `trellis.par.set`

`col.whitebg` returns a similar (but smaller) list that is suitable as the theme argument to `trellis.device` and `trellis.par.set`. It contains settings values which provide colors suitable for plotting on a white background. Note that the name `col.whitebg` is somewhat of a misnomer, since it actually sets the background to transparent rather than white.

`trellis.par.get` and `trellis.par.set` can be used to query and modify the settings *after* a device has been initialized. The `par.settings` argument to high level functions, described in [xyplot](#), can be used to attach transient settings to a "trellis" object.

## Description

Functions used to query, display and modify graphical parameters for fine control of Trellis displays. Modifications are made to the settings for the currently active device only.

## Usage

```
trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
show.settings(x = NULL)
```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name   | A character string giving the name of a component. If unspecified in <code>trellis.par.get()</code> , the return value is a named list containing all the current settings (this can be used to get the valid values for name).                                                                                                                                                                                                                                                                                                                                                       |
| value  | a list giving the desired value of the component. Components that are already defined as part of the current settings but are not mentioned in value will remain unchanged.                                                                                                                                                                                                                                                                                                                                                                                                           |
| theme  | a list describing how to change the settings, similar to what is returned by <code>trellis.par.get()</code> . This is purely for convenience, allowing multiple calls to <code>trellis.par.set</code> to be condensed into one. The name of each component must be a valid name as described above, with the corresponding value a valid value as described above.<br><br>As in <code>trellis.device</code> , theme can also be a function that produces such a list when called. The function name can be supplied as a quoted string.                                               |
| ...    | Multiple settings can be specified in name = value form. Equivalent to calling with <code>theme = list(...)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| warn   | A logical flag, indicating whether a warning should be issued when <code>trellis.par.get</code> is called when no graphics device is open.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| strict | Usually a logical flag, indicating whether the value should be interpreted strictly. Usually, assignment of value to the corresponding named component is fuzzy in the sense that sub-components that are absent from value but not currently NULL are retained. By specifying <code>strict = TRUE</code> , such values will be removed.<br><br>An even stricter interpretation is allowed by specifying <code>strict</code> as a numeric value larger than 1. In that case, top-level components not specified in the call will also be removed. This is primarily for internal use. |
| x      | optional list of components that change the settings (any valid value of theme). These are used to modify the current settings (obtained by <code>trellis.par.get</code> ) before they are displayed.                                                                                                                                                                                                                                                                                                                                                                                 |

## Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and windows, one for black and white plots (mostly useful for postscript) and one for color printers (color postscript, pdf).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a postscript device will not alter the `x11` settings, which will remain in effect whenever an `x11` device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently ACTIVE device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the `name` component of the current active device settings to `value`.

`trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```
add.line <- trellis.par.get("add.line")
```

```
add.line$col <- "red"
```

```
trellis.par.set("add.line", add.line)
```

More convenient (but not S compatible) ways to do this are

```
trellis.par.set(list(add.line = list(col = "red")))
```

and

```
trellis.par.set(add.line = list(col = "red"))
```

The actual list of the components in `trellis.settings` has not been finalized, so I'm not attempting to list them here. The current value can be obtained by `print(trellis.par.get())`. Most names should be self-explanatory.

`show.settings` provides a graphical display summarizing some of the values in the current settings.

## Value

`trellis.par.get` returns a list giving parameters for that component. If `name` is missing, it returns the full list.

Most of the settings are graphical parameters that control various elements of a lattice plot. For details, see the examples below. The more unusual settings are described here.

**grid.pars** Grid graphical parameters that are in effect globally unless overridden by specific settings.

**fontsize** A list of two components (each a numeric scalar), `text` and `points`, for text and symbols respectively.

`clip` A list of two components (each a character string, either "on" or "off"), `panel` and `strip`.  
`axis.components` A list with four components (left, top, right, bottom), each a list giving numeric multipliers named `tck`, `pad1`, and `pad2` for corresponding grid layout units.  
`layout.heights` A list with numeric multipliers for grid layout heights.  
`layout.widths` A list with numeric multipliers for grid layout widths.

### Note

In some ways, `trellis.par.get` and `trellis.par.set` together are a replacement for the `par` function used in traditional R graphics. In particular, changing `par` settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter system *does* have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the `grid.pars` component (see `gpar` for a list of valid parameter names).

### Examples

```
show.settings()

tp <- trellis.par.get()

unusual <- c("grid.pars", "fontsize", "clip", "axis.components",
 "layout.heights", "layout.widths")

for (u in unusual) tp[[u]] <- NULL
names.tp <- lapply(tp, names)
unames <- sort(unique(unlist(names.tp)))
ans <- matrix(0, nrow = length(names.tp), ncol = length(unames))
rownames(ans) <- names(names.tp)
colnames(ans) <- unames
for (i in seq_along(names.tp))
 ans[i,] <- as.numeric(unames %in% names.tp[[i]])
ans <- ans[, order(-colSums(ans))]
ans <- ans[order(rowSums(ans)),]
ans[ans == 0] <- NA

levelplot(t(ans), colorkey = FALSE,
 scales = list(x = list(rot = 90)),
 panel = function(x, y, z, ...) {
 panel.abline(v = unique(as.numeric(x)),
 h = unique(as.numeric(y)),
 col = "darkgrey")
 panel.xyplot(x, y, pch = 16 * z, ...)
 },
 xlab = "Graphical parameters",
 ylab = "Setting names")
```

## C.03 simpleTheme

*Function to generate a simple theme***Description**

Simple interface to generate a list appropriate as a theme, typically used as the `par.settings` argument in a high level call

**Usage**

```
simpleTheme(col, alpha,
 cex, pch, lty, lwd, font, fill, border,
 col.points, col.line,
 alpha.points, alpha.line)
```

**Arguments**

`col, col.points, col.line`

A color specification. `col` is used for components `"plot.symbol"`, `"plot.line"`, `"plot.polygon"`, `"superpose.symbol"`, `"superpose.line"`, and `"superpose.polygon"`. `col.points` overrides `col`, but is used only for `"plot.symbol"` and `"superpose.symbol"`. Similarly, `col.line` overrides `col` for `"plot.line"` and `"superpose.line"`. The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without "superpose" in their name).

`alpha, alpha.points, alpha.line`

A numeric alpha transparency specification. The same rules as `col`, etc., apply.

`cex, pch, font`

Parameters for points. Applicable for components `plot.symbol` (for which only the first component is used) and `superpose.symbol` (for which the arguments can be vectors).

`lty, lwd`

Parameters for lines. Applicable for components `plot.line` (for which only the first component is used) and `superpose.line` (for which the arguments can be vectors).

`fill`

fill color, applicable for components `plot.symbol`, `plot.polygon`, `superpose.symbol`, and `superpose.polygon`.

`border`

border color, applicable for components `plot.polygon` and `superpose.polygon`.

**Details**

The appearance of a lattice display depends partly on the "theme" active when the display is plotted (see [trellis.device](#) for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the `auto.key` argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the `par.settings` argument, which is usually tedious to construct as it is a nested list. The `simpleTheme` function can be used in such situations as a wrapper that generates a suitable list given parameters in simple `name=value` form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

**Value**

A list that would work as the theme argument to `trellis.device` and `trellis.par.set`, or as the `par.settings` argument to any high level lattice function such as `xyplot`.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>, based on a suggestion from John Maindonald.

**See Also**

`trellis.device`, `xyplot`, `Lattice`

**Examples**

```
str(simpleTheme(pch = 16))

dotplot(variety ~ yield | site, data = barley, groups = year,
 auto.key = list(space = "right"),
 par.settings = simpleTheme(pch = 16),
 xlab = "Barley Yield (bushels/acre) ",
 aspect=0.5, layout = c(1,6))
```

---

C.04 lattice.options    *Low-level Options Controlling Behaviour of Lattice*

---

**Description**

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level maybe useful in certain cases.

**Usage**

```
lattice.options(...)
lattice.getOption(name)
```

**Arguments**

|                   |                                                                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code> | character giving the name of a setting                                                                                                                                                                                                                                                      |
| <code>...</code>  | new options can be defined, or existing ones modified, using one or more arguments of the form <code>name = value</code> or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments. |

## Details

These functions are modeled on options and `getOption`, and behave similarly for the most part. Some of the available components are documented here, but not all. The purpose of the ones not documented are either fairly obvious, or not of interest to the end-user.

`panel.error` A function, or NULL. If the former, every call to the panel function will be wrapped inside `tryCatch` with the specified function as an error handler. The default is to use the `panel.error` function. This prevents the plot from failing due to errors in a single panel, and leaving the grid operations in an unmanageable state. If set to NULL, errors in panel functions will not be caught using `tryCatch`.

`save.object` Logical flag indicating whether a "trellis" object should be saved when plotted for subsequent retrieval and further manipulation. Defaults to TRUE.

`layout.widths`, `layout.heights` Controls details of the default space allocation in the grid layout created in the course of plotting a "trellis" object. Each named component is a list of arguments to the `grid` function `unit` (x, units, and optionally data).

Usually not of interest to the end-user, who should instead use the similarly named component in the graphical settings, modifiable using `trellis.par.set`.

`drop.unused.levels` A list of two components named `cond` and `data`, both logical flags. The flags indicate whether the unused levels of factors (conditioning variables and primary variables respectively) will be dropped, which is usually relevant when a subsetting operation is performed or an 'interaction' is created. See `xyplot` for more details. Note that this does not control dropping of levels of the 'groups' argument.

`legend.bbox` A character string, either "full" or "panel". This determines the interpretation of x and y when `space="inside"` in key (determining the legend; see `xyplot`): either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

`default.args` A list giving default values for various standard arguments: `as.table`, `auto.key`, `aspect`, `between`, `grid`, `skip`, `strip`, `xscale.components`, `yscale.components`, and `axis`.

`highlight.gpar` A list giving arguments to `gpar` used to highlight a viewport chosen using `trellis.focus`.

`banking` The banking function. See `banking`.

`axis.padding` List with components named "numeric" and "factor", both scalar numbers. Panel limits are extended by this amount, to provide padding for numeric and factor scales respectively. The value for numeric is multiplicative, whereas factor is additive.

`skip.boundary.labels` Numeric scalar between 0 and 1. Tick marks that are too close to the limits are not drawn unless explicitly requested. The limits are contracted by this proportion, and anything outside is skipped.

`interaction.sep` The separator for creating interactions with the extended formula interface (see `xyplot`).

`optimize.grid` Logical flag, FALSE by default. Complicated grid unit calculations can be slow. Sometimes these can be optimized at the cost of potential loss of accuracy. This option controls whether such optimization should be applied.

`axis.units` List determining default units for axis components. Should not be of interest to the end-user.

In addition, there is an option for the default `prepanel` and `panel` function for each high-level function; e.g., `panel.xyplot` and `prepanel.default.xyplot` for `xyplot`. The options for the others have similarly patterned names.

**Value**

`lattice.getOption` returns the value of a single component, whereas `lattice.options` always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by `lattice.options`. If called without any arguments, the full list is returned.

**Examples**

```
names(lattice.options())
str(lattice.getOption("layout.widths"), max.level = 2)

Not run:
change default settings for subsequent plots
lattice.options(default.args = list(as.table = TRUE,
 grid = TRUE,
 auto.key = TRUE))

End(Not run)
```

---

C.05 print.trellis      *Plot and Summarize Trellis Objects*

---

**Description**

The `print` and `plot` methods produce a graph from a "trellis" object. The `print` method is necessary for automatic plotting. `plot` method is essentially an alias, provided for convenience. The `summary` method gives a textual summary of the object. `dim` and `dimnames` describe the cross-tabulation induced by conditioning. `panel.error` is the default handler used when an error occurs while executing the panel function.

**Usage**

```
S3 method for class 'trellis'
plot(x, position, split,
 more = FALSE, newpage = TRUE,
 packet.panel = packet.panel.default,
 draw.in = NULL,
 panel.height = lattice.getOption("layout.heights")$panel,
 panel.width = lattice.getOption("layout.widths")$panel,
 save.object = lattice.getOption("save.object"),
 panel.error = lattice.getOption("panel.error"),
 prefix,
 ...)
```

```
S3 method for class 'trellis'
print(x, ...)

S3 method for class 'trellis'
summary(object, ...)

S3 method for class 'trellis'
dim(x)
S3 method for class 'trellis'
dimnames(x)

panel.error(e)
```

### Arguments

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, object</code>                 | an object of class "trellis"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>position</code>                  | a vector of 4 numbers, typically <code>c(xmin, ymin, xmax, ymax)</code> that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of <code>x</code> is to be positioned. The coordinate system for this rectangle is [0-1] in both the <code>x</code> and <code>y</code> directions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>split</code>                     | a vector of 4 integers, <code>c(x,y,nx,ny)</code> , that says to position the current plot at the <code>x,y</code> position in a regular array of <code>nx</code> by <code>ny</code> plots. (Note: this has origin at top left)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>more</code>                      | A logical specifying whether more plots will follow on this page.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>newpage</code>                   | A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>packet.panel</code>              | a function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the default, namely the function <code>packet.panel.default</code> , whose help page details the arguments supplied to whichever function is specified as the <code>packet.panel</code> argument.                    |
| <code>draw.in</code>                   | An optional (grid) viewport (used as the <code>name</code> argument in <code>downViewport</code> ) in which the plot is to be drawn. If specified, the <code>newpage</code> argument is ignored. This feature is not well-tested.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>panel.width, panel.height</code> | lists with 2 components, that should be valid <code>x</code> and <code>units</code> arguments to <code>unit()</code> (the <code>data</code> argument cannot be specified currently, but can be considered for addition if needed). The resulting unit object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.<br><br>Note that this option should not be used in conjunction with non-default values of the <code>aspect</code> argument in the original high level call (no error will be produced, but the resulting behaviour is undefined). |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>save.object</code> | logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel's data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the update method on the current plot, even if it was not assigned to a variable explicitly. For more details, see <a href="#">trellis.focus</a> .                                                                                                                                                                                                                     |
| <code>panel.error</code> | a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using <a href="#">tryCatch</a> ) and supplied as the only argument to <code>panel.error</code> . The default behaviour (implemented as the <code>panel.error</code> function) is to print the corresponding error message in the panel and continue. To stop execution on error, use <code>panel.error = stop</code> .<br>Normal error recovery and debugging tools are unhelpful when <code>tryCatch</code> is used. <code>tryCatch</code> can be completely bypassed by setting <code>panel.error</code> to <code>NULL</code> . |
| <code>prefix</code>      | A character string acting as a prefix identifying the plot of a "trellis" object, primarily used in constructing viewport and grob names, to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (specifically, "plot_01", "plot_02", etc.). If supplied explicitly, this must be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently ":").                                                                                                                                                        |
| <code>e</code>           | an error condition caught by <a href="#">tryCatch</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>...</code>         | extra arguments, ignored by the print method. All arguments to the plot method are passed on to the print method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### Details

This is the default print method for objects of class "trellis", produced by calls to functions like `xyplot`, `bwplot` etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments `split` and `position`.

When `newpage = FALSE`, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The `draw.in` argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in `x` (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.

Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see [trellis.focus](#).

### Note

Unlike S-PLUS, trying to position a multipage display (using `position` and/or `split`) will mess things up.

**Examples**

```

p11 <- histogram(~ height | voice.part, data = singer, xlab="Height")
p12 <- densityplot(~ height | voice.part, data = singer, xlab = "Height")
p2 <- histogram(~ height, data = singer, xlab = "Height")

simple positioning by split
print(p11, split=c(1,1,1,2), more=TRUE)
print(p2, split=c(1,2,1,2))

Combining split and position:
print(p11, position = c(0,0,.75,.75), split=c(1,1,1,2), more=TRUE)
print(p12, position = c(0,0,.75,.75), split=c(1,2,1,2), more=TRUE)
print(p2, position = c(.5,.75,1,1), more=FALSE)

Using seekViewport

repeat same plot, with different polynomial fits in each panel
xyplot(Armed.Forces ~ Year, longley, index.cond = list(rep(1, 6)),
 layout = c(3, 2),
 panel = function(x, y, ...)
 {
 panel.xyplot(x, y, ...)
 fm <- lm(y ~ poly(x, panel.number()))
 llines(x, predict(fm))
 })

Not run:
grid::seekViewport(trellis.vpname("panel", 1, 1))
cat("Click somewhere inside the first panel:\n")
ltext(grid::grid.locator(), lab = "linear")

End(Not run)

grid::seekViewport(trellis.vpname("panel", 1, 1))
grid::grid.text("linear")

grid::seekViewport(trellis.vpname("panel", 2, 1))
grid::grid.text("quadratic")

grid::seekViewport(trellis.vpname("panel", 3, 1))
grid::grid.text("cubic")

grid::seekViewport(trellis.vpname("panel", 1, 2))
grid::grid.text("degree 4")

grid::seekViewport(trellis.vpname("panel", 2, 2))
grid::grid.text("degree 5")

grid::seekViewport(trellis.vpname("panel", 3, 2))
grid::grid.text("degree 6")

```

**Description**

Update method for objects of class "trellis", and a way to retrieve the last printed trellis object (that was saved).

**Usage**

```
S3 method for class 'trellis'
update(object,
 panel,
 aspect,
 as.table,
 between,
 key,
 auto.key,
 legend,
 layout,
 main,
 page,
 par.strip.text,
 prepanel,
 scales,
 skip,
 strip,
 strip.left,
 sub,
 xlab,
 ylab,
 xlab.top,
 ylab.right,
 xlim,
 ylim,
 xscale.components,
 yscale.components,
 axis,
 par.settings,
 plot.args,
 lattice.options,
 index.cond,
 perm.cond,
 ...)

S3 method for class 'trellis'
t(x)

S3 method for class 'trellis'
x[i, j, ..., drop = FALSE]

trellis.last.object(..., prefix)
```

**Arguments**

|                                                                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                        |

Names are not currently allowed.                                                                                                                                                                                                                   |
| <code>drop</code>                                                                                                                                                                                                                                                                                                        | logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were FALSE.                                                                                                                                                     |
| <code>panel, aspect, as.table, between, key, auto.key, legend, layout, main, page, par.strip.text, prepanel, scales, skip, strip, strip.left, sub, xlab, ylab, xlab.top, ylab.right, xlim, ylim, xscale.components, yscale.components, axis, par.settings, plot.args, lattice.options, index.cond, perm.cond, ...</code> | arguments that will be used to update object. See details below.                                                                                                                                                                                                       |
| <code>prefix</code>                                                                                                                                                                                                                                                                                                      | A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See <a href="#">trellis.focus</a> . |

**Details**

All high level lattice functions such as `xyplot` produce an object of (S3) class "trellis", which is usually displayed by its `print` method. However, the object itself can be manipulated and modified to a large extent using the `update` method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the `update` method as well, with some exceptions. Generally speaking, anything that would need to change the data within each panel is a no-no (this includes the formula, data, groups, subscripts and subset). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by `update`, but the ones listed above should work. The purpose of these arguments are described in the help page for [xyplot](#). Any other argument is added to the list of arguments to be passed to the `panel` function. Because of their somewhat special nature, updates to objects produced by `cloud` and `wireframe` do not work very well yet.

The `"["` method is a convenient shortcut for updating `index.cond`. The `t` method is a convenient shortcut for updating `perm.cond` in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching ('transposing') their order.

The `print` method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, `trellis.last.object` can retrieve it. By default, the last object plotted is retrieved, but if multiple objects are plotted on the current page, then others can be retrieved using the appropriate `prefix` argument. If [trellis.last.object](#) is called with arguments, these are used to update the retrieved object before returning it.

**Value**

An object of class `trellis`, by default plotted by `print.trellis`. `trellis.last.object` returns NULL if no saved object is available.

C.07 shingles

*shingles*

---

**Description**

Functions to handle shingles

**Usage**

```
shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)

S3 method for class 'shingle'
plot(x, panel, xlab, ylab, ...)

S3 method for class 'shingle'
print(x, showValues = TRUE, ...)

S3 method for class 'shingleLevel'
as.character(x, ...)

S3 method for class 'shingleLevel'
print(x, ...)

S3 method for class 'shingle'
summary(object, showValues = FALSE, ...)

S3 method for class 'shingle'
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)
```

**Arguments**

|                                |                                                                                                                                                                                                                        |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                 | numeric variable or R object, shingle in <code>plot.shingle</code> and <code>x[]</code> . An object (list of intervals) of class "shingleLevel" in <code>print.shingleLevel</code>                                     |
| <code>object</code>            | shingle object to be summarized                                                                                                                                                                                        |
| <code>showValues</code>        | logical, whether to print the numeric part. If FALSE, only the intervals are printed                                                                                                                                   |
| <code>intervals</code>         | numeric vector or matrix with 2 columns                                                                                                                                                                                |
| <code>subset</code>            | logical vector                                                                                                                                                                                                         |
| <code>drop</code>              | whether redundant shingle levels are to be dropped                                                                                                                                                                     |
| <code>panel, xlab, ylab</code> | standard Trellis arguments (see <a href="#">xyplot</a> )                                                                                                                                                               |
| <code>...</code>               | other arguments, passed down as appropriate. For example, extra arguments to <code>equal.count</code> are passed on to <code>co.intervals</code> . graphical parameters can be passed as arguments to the plot method. |

**Details**

A shingle is a data structure used in Trellis, and is a generalization of factors to ‘continuous’ variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the ‘levels’ of the shingle. The `levels` and `nlevels` functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of `levels()` applied to a shingle. For use in labelling, the `as.character` method can be used to convert levels of a shingle to character strings.

`equal.count` converts `x` to a shingle using the equal count algorithm. This is essentially a wrapper around `co.intervals`. All arguments are passed to `co.intervals`.

`shingle` creates a shingle using the given intervals. If `intervals` is a vector, these are used to form 0 length intervals.

`as.shingle` returns `shingle(x)` if `x` is not a shingle.

`is.shingle` tests whether `x` is a shingle.

`plot.shingle` displays the ranges of shingles via rectangles. `print.shingle` and `summary.shingle` describe the shingle object.

**Value**

`x$intervals` for `levels.shingle(x)`, logical for `is.shingle`, an object of class "trellis" for plot (printed by default by `print.trellis`), and an object of class "shingle" for the others.

|                              |                                                                |
|------------------------------|----------------------------------------------------------------|
| D <code>draw.colorkey</code> | <i>Produce a colorkey typically for <code>levelplot</code></i> |
|------------------------------|----------------------------------------------------------------|

---

**Description**

Creates (and optionally draws) a grid frame grob representing a color key that can be placed in other grid-based plots. Primarily used by `levelplot` when a color key is requested.

**Usage**

```
draw.colorkey(key, draw = FALSE, vp = NULL)
```

**Arguments**

|                   |                                                                                                                                                                     |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>key</code>  | A list determining the key. See documentation for <a href="#">levelplot</a> , in particular the section describing the <code>colorkey</code> argument, for details. |
| <code>draw</code> | A scalar logical, indicating whether the grob is to be drawn.                                                                                                       |
| <code>vp</code>   | The viewport in which to draw the grob, if applicable.                                                                                                              |

**Value**

A grid frame object (that inherits from "grob")

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

|------------|--------------------------------|
| D draw.key | <i>Produce a Legend or Key</i> |
|------------|--------------------------------|

---

### Description

Produces (and possibly draws) a Grid frame grob which is a legend (aka key) that can be placed in other Grid plots.

### Usage

```
draw.key(key, draw=FALSE, vp=NULL, ...)
```

### Arguments

|      |                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------|
| key  | A list determining the key. See documentation for <code>xyplot</code> , in particular the section describing the key argument, for details. |
| draw | logical, whether the grob is to be drawn.                                                                                                   |
| vp   | viewport                                                                                                                                    |
| ...  | ignored                                                                                                                                     |

### Value

A Grid frame object (that inherits from 'grob').

|----------------|------------------------------------------------------------------------------------------|
| D level.colors | <i>A function to compute false colors representing a numeric or categorical variable</i> |
|----------------|------------------------------------------------------------------------------------------|

---

### Description

Calculates false colors from a numeric variable (including factors, using their numeric codes) given a color scheme and breakpoints.

### Usage

```
level.colors(x, at, col.regions, colors = TRUE, ...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | A numeric or <a href="#">factor</a> variable.                                                                                                                                                                                                                         |
| <code>at</code>          | A numeric variable of breakpoints defining intervals along the range of <code>x</code> .                                                                                                                                                                              |
| <code>col.regions</code> | A specification of the colors to be assigned to each interval defined by <code>at</code> . This could be either a vector of colors, or a function that produces a vector of colors when called with a single argument giving the number of colors. See details below. |
| <code>colors</code>      | logical indicating whether colors should be computed and returned. If FALSE, only the indices representing which interval (among those defined by <code>at</code> ) each value in <code>x</code> falls into is returned.                                              |
| <code>...</code>         | Extra arguments, ignored.                                                                                                                                                                                                                                             |

**Details**

If `at` has length `n`, then it defines `n-1` intervals. Values of `x` outside the range of `at` are not assigned to an interval, and the return value is NA for such values.

Colors are chosen by assigning a color to each of the `n-1` intervals. If `col.regions` is a palette function (such as [topo.colors](#), or the result of calling [colorRampPalette](#)), it is called with `n-1` as an argument to obtain the colors. Otherwise, if there are exactly `n-1` colors in `col.regions`, these get assigned to the intervals. If there are fewer than `n-1` colors, `col.regions` gets recycled. If there are more, a more or less equally spaced (along the length of `col.regions`) subset is chosen.

**Value**

A vector of the same length as `x`. Depending on the `colors` argument, this could be either a vector of colors (in a form usable by R), or a vector of integer indices representing which interval the values of `x` fall in.

**Examples**

```
depth.col <-
 with(quakes,
 level.colors(depth, at = do.breaks(range(depth), 30),
 col.regions = hcl.colors))

xyplot(lat ~ long | equal.count(stations), quakes,
 strip = strip.custom(var.name = "Stations"),
 colours = depth.col,
 panel = function(x, y, colours, subscripts, ...) {
 panel.xyplot(x, y, pch = 21, col = "transparent",
 fill = colours[subscripts], ...)
 })
```

---

`D make.groups`*Grouped data from multiple vectors*

---

**Description**

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

**Usage**

```
make.groups(...)
```

**Arguments**

... one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

**Value**

When all the input arguments are vectors, a data frame with two columns

data all the vectors supplied, concatenated

which factor indicating which vector the corresponding data value came from

When all the input arguments are data frames, the result of `rbind` applied to them, along with an additional which column as described above.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**Examples**

```
sim.dat <-
 make.groups(uniform = runif(200),
 exponential = rexp(175),
 lognormal = rlnorm(150),
 normal = rnorm(125))
qqmath(~ data | which, sim.dat, scales = list(y = "free"))
```

D *simpleKey**Function to generate a simple key***Description**

Simple interface to generate a list appropriate for `draw.key`

**Usage**

```
simpleKey(text, points = TRUE,
 rectangles = FALSE,
 lines = FALSE,
 col, cex, alpha, font,
 fontface, fontfamily,
 lineheight, ...)
```

**Arguments**

|                                                                      |                                                                                                                                                       |
|----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>text</code>                                                    | character or expression vector, to be used as labels for levels of the grouping variable                                                              |
| <code>points</code>                                                  | logical                                                                                                                                               |
| <code>rectangles</code>                                              | logical                                                                                                                                               |
| <code>lines</code>                                                   | logical                                                                                                                                               |
| <code>col, cex, alpha, font, fontface, fontfamily, lineheight</code> | Used as top-level components of the list produced, to be used for the text labels. Defaults to the values in <code>trellis.par.get("add.text")</code> |
| <code>...</code>                                                     | further arguments added to the list, eventually passed to <code>draw.key</code>                                                                       |

**Details**

A lattice plot can include a legend (key) if an appropriate list is specified as the key argument to a high level Lattice function such as `xyplot`. This key can be very flexible, but that flexibility comes at a cost: this list needs to be fairly complicated even in simple situations. `simpleKey` is designed as a useful shortcut in the common case of a key drawn in conjunction with a grouping variable, using the default graphical settings.

The `simpleKey` function produces a suitable key argument using a simpler interface. The resulting list will use the `text` argument as a text component, along with at most one set each of `points`, `rectangles`, and `lines`. The number of entries (rows) in the key will be the length of the `text` component. The graphical parameters for the additional components will be derived from the default graphical settings (wherein lies the simplification, as otherwise these would have to be provided explicitly).

Calling `simpleKey` directly is usually unnecessary. It is most commonly invoked (during the plotting of the "trellis" object) when the `auto.key` argument is supplied in a high-level plot with a `groups` argument. In that case, the `text` argument of `simpleKey` defaults to `levels(groups)`, and the defaults for the other arguments depend on the relevant high-level function. Note that these defaults can be overridden by supplying `auto.key` as a list containing the replacement values.

**Value**

A list that would work as the key argument to `xyplot`, etc.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

---

D strip.default

*Default Trellis Strip Function*

---

**Description**

`strip.default` is the function that draws the strips by default in Trellis plots. Users can write their own strip functions, but most commonly this involves calling `strip.default` with a slightly different arguments. `strip.custom` provides a convenient way to obtain new strip functions that differ from `strip.default` only in the default values of certain arguments.

**Usage**

```
strip.default(which.given,
 which.panel,
 var.name,
 factor.levels,
 shingle.intervals,
 strip.names = c(FALSE, TRUE),
 strip.levels = c(TRUE, FALSE),
 sep = " : ",
 style = 1,
 horizontal = TRUE,
 bg = trellis.par.get("strip.background")$col[which.given],
 fg = trellis.par.get("strip.shingle")$col[which.given],
 par.strip.text = trellis.par.get("add.text"))
strip.custom(...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>which.given</code> | integer index specifying which of the conditioning variables this strip corresponds to.                                                                                                                                                                                                                                                                        |
| <code>which.panel</code> | vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of <a href="#">which.packet</a> , which is a more accurate name.                                 |
| <code>var.name</code>    | vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of <code>strip.names</code> and <code>style</code> (see below). By default, the names are shown for shingles, but not for factors. |

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>factor.levels</code>     | vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with <code>which.given</code> . Whether these levels are shown on the strip depends on the values of <code>strip.levels</code> and <code>style</code> (see below). <code>factor.levels</code> may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in <code>par.strip.text</code> (see <a href="#">xyplot</a> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>shingle.intervals</code> | if the current strip corresponds to a shingle, this should be a 2-column matrix giving the levels of the shingle. (of the form that would be produced by <code>printing.levels(shingle)</code> ). Otherwise, it should be <code>NULL</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>strip.names</code>       | a logical vector of length 2, indicating whether or not the name of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively. This argument is ignored for a factor when <code>style</code> is not one of 1 and 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>strip.levels</code>      | a logical vector of length 2, indicating whether or not the level of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>sep</code>               | character or expression, serving as a separator if the name and level are both to be shown.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>style</code>             | integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the current level of a factor is encoded. Ignored for shingles (actually, when <code>shingle.intervals</code> is non-null.<br><br>The best way to find out what effect the value of <code>style</code> has is to try them out. Here is a short description: for a style value of 1, the strip is colored in the background color with the strip text (as determined by other arguments) centered on it. A value of 3 is the same, except that a part of the strip is colored in the foreground color, indicating the current level of the factor. For styles 2 and 4, the part corresponding to the current level remains colored in the foreground color, however, for <code>style = 2</code> , the remaining part is not colored at all, whereas for 4, it is colored with the background color. For both these, the names of all the levels of the factor are placed on the strip from left to right. Styles 5 and 6 produce the same effect (they are subtly different in S, this implementation corresponds to 5), they are similar to style 1, except that the strip text is not centered, it is instead positioned according to the current level.<br><br>Note that unlike S-PLUS, the default value of <code>style</code> is 1. <code>strip.names</code> and <code>strip.levels</code> have no effect if <code>style</code> is not 1 or 3. |
| <code>horizontal</code>        | logical, specifying whether the labels etc should be horizontal. <code>horizontal=FALSE</code> is useful for strips on the left of panels using <code>strip.left=TRUE</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>par.strip.text</code>    | list with parameters controlling the text on each strip, with components <code>col</code> , <code>cex</code> , <code>font</code> , etc.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>bg</code>                | strip background color.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <code>...</code>               | arguments to be passed on to <code>strip.default</code> , overriding whatever value it would have normally assumed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

default strip function for trellis functions. Useful mostly because of the `style` argument — non-default styles are often more informative, especially when the names of the levels of the factor `x` are

small. Traditional use is as `strip = function(...) strip.default(style=2,...)`, though this can be simplified by the use of `strip.custom`.

### Value

`strip.default` is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. `strip.custom` returns a function that is similar to `strip.default`, but with different defaults for the arguments specified in the call.

### Examples

```
Traditional use
xyplot(Petal.Length ~ Petal.Width | Species, iris,
 strip = function(..., style) strip.default(..., style = 4))

equivalent call using strip.custom
xyplot(Petal.Length ~ Petal.Width | Species, iris,
 strip = strip.custom(style = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris,
 strip = FALSE,
 strip.left = strip.custom(style = 4, horizontal = FALSE))
```

D trellis.object

*A Trellis Plot Object*

---

### Description

This class of objects is returned by high level lattice functions, and is usually plotted by default by its [print](#) method.

### Details

A trellis object, as returned by high level lattice functions like [xyplot](#), is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: `as.table`, `layout`, `page`, `panel`, `prepanel`, `main`, `sub`, `par.strip.text`, `strip`, `skip`, `xlab` `ylib`, `par.settings`, `lattice.options` and `plot.args`. Some other typical components are:

`formula` the Trellis formula used in the call  
`index.cond` list with index for each of the conditioning variables  
`perm.cond` permutation of the order of the conditioning variables  
`aspect.fill` logical, whether aspect is "fill"  
`aspect.ratio` numeric, aspect ratio to be used if `aspect.fill` is FALSE

`call` call that generated the object.  
`condlevels` list with levels of the conditioning variables  
`legend` list describing the legend(s) to be drawn  
`panel.args` a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.  
`panel.args.common` a list containing the arguments common to all the panel functions in name=value form  
`x.scales` list describing x-scale, can consist of several other lists, paralleling `panel.args`, if x-relation is not "same"  
`y.scales` list describing y-scale, similar to `x.scales`  
`x.between` numeric vector of interpanel x-space  
`y.between` numeric vector of interpanel y-space  
`x.limits` numeric vector of length 2 or list, giving x-axis limits  
`y.limits` similar to `x.limits`  
`packet.sizes` array recording the number of observations in each packet

E interaction

---

*Functions to Interact with Lattice Plots*

---

**Description**

The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

**Usage**

```

panel.identify(x, y = NULL,
 subscripts = seq_along(x),
 labels = subscripts,
 n = length(x), offset = 0.5,
 threshold = 18, ## in points, roughly 0.25 inches
 panel.args = trellis.panelArgs(),
 ...)
panel.identify.qqmath(x, distribution, groups, subscripts, labels,
 panel.args = trellis.panelArgs(),
 ...)
panel.identify.cloud(x, y, z, subscripts,

```

```

 perspective, distance,
 xlim, ylim, zlim,
 screen, R.mat, aspect, scales.3d,
 ...,
 panel.3d.identify,
 n = length(subscripts),
 offset = 0.5,
 threshold = 18,
 labels = subscripts,
 panel.args = trellis.panelArgs())
panel.link.splom(threshold = 18, verbose = getOption("verbose"), ...)
panel.brush.splom(threshold = 18, verbose = getOption("verbose"), ...)

trellis.panelArgs(x, packet.number)

```

### Arguments

|                                   |                                                                                                                    |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>x, y, z</code>              | variables defining the contents of the panel. In the case of <code>trellis.panelArgs</code> , a "trellis" object.  |
| <code>n</code>                    | the number of points to identify by default (overridden by a right click)                                          |
| <code>subscripts</code>           | an optional vector of integer indices associated with each point. See details below.                               |
| <code>labels</code>               | an optional vector of labels associated with each point. Defaults to <code>subscripts</code>                       |
| <code>distribution, groups</code> | typical panel arguments of <code>panel.qqmath</code> . These will usually be obtained from <code>panel.args</code> |

|                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| offset                                                                    | the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The offset specifies (in "char" units) how far from the identified point the labels should be printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| threshold                                                                 | threshold in grid's "points" units. Points further than these from the mouse click position are not considered                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| panel.args                                                                | list that contains components names x (and usually y), to be used if x is missing. Typically, when called after <code>trellis.focus</code> , this would appropriately be the arguments passed to that panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, scales.3d | arguments as passed to <code>panel.cloud</code> . These are required to recompute the relevant three-dimensional projections in <code>panel.identify.cloud</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| panel.3d.identify                                                         | the function that is responsible for the actual interaction once the data rescaling and rotation computations have been done. By default, an internal function similar to <code>panel.identify</code> is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| name                                                                      | <p>A character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most of the ones that end-users may find interesting. <code>trellis.vpname</code> and <code>trellis.focus</code> deal with viewport names only, and only accept the values explicitly listed above. <code>trellis.grobname</code> is meant to create names for grobs, and can currently accept any value.</p> <p>If name, as well as column and row is missing in a call to <code>trellis.focus</code>, the user can click inside a panel (or an associated strip) to focus on that panel. Note however that this assumes equal width and height for each panel, and may not work when this is not true.</p> <p>When name is "panel", "strip", or "strip.left", column and row must also be specified. When name is "legend", side must also be specified.</p> |
| column, row                                                               | integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with <code>as.table=TRUE</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| guess                                                                     | logical. If TRUE, and the display has only one panel, that panel will be automatically selected by a call to <code>trellis.focus</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| side                                                                      | character string, relevant only for legends (i.e., when name="legend"), indicating their position. Partial specification is allowed, as long as it is unambiguous.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| clip.off                                                                  | logical, whether clipping should be off, relevant when name is "panel" or "strip". This is necessary if axes are to be drawn outside the panel or strip. Note that setting <code>clip.off=FALSE</code> does not necessarily mean that clipping is on; that is determined by conditions in effect during printing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| type                                                                      | <p>A character string specifying whether the grob is specific to a particular panel or strip.</p> <p>When type is "panel", "strip", or "strip.left", information about the panel is added to the grob name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| group                                                                     | <p>An integer specifying whether the grob is specific to a particular group within the plot.</p> <p>When group is greater than zero, information about the group is added to the grob name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>which.given</code> , <code>which.panel</code> | <p>integers, indicating which conditional variable is being represented (within a strip) and the current levels of the conditional variables.</p> <p>When <code>which.panel</code> has length greater than 1, and the type is "strip" or "strip.left", information about the conditional variable is added to the grob name.</p>                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>prefix</code>                                 | <p>A character string acting as a prefix identifying the plot of a "trellis" object, primarily used to distinguish otherwise equivalent viewports in different plots. This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the <code>prefix</code> argument in <code>print.trellis</code>.</p> <p>Users should not usually need to supply a value for this argument except to interact with an existing plot other than the one plotted last.</p> <p>For <code>switchFocus</code>, ignored except when it does not match the prefix of the currently active plot, in which case an error occurs.</p> |
| <code>highlight</code>                              | <p>logical, whether the viewport being assigned focus should be highlighted. For <code>trellis.focus</code>, the default is TRUE in interactive mode, and <code>trellis.switchFocus</code> by default preserves the setting currently active.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>packet.number</code>                          | <p>integer, which panel to get data from. See <code>packet.number</code> for details on how this is calculated</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>verbose</code>                                | <p>whether details will be printed</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>                                    | <p>For <code>panel.identify.qqmath</code>, extra parameters are passed on to <code>panel.identify</code>. For <code>panel.identify</code>, extra arguments are treated as graphical parameters and are used for labelling. For <code>trellis.focus</code> and <code>trellis.switchFocus</code>, these are used (in combination with <code>lattice.options</code>) for highlighting the chosen viewport if so requested. Graphical parameters can be supplied for <code>panel.link.splom</code>.</p>                                                                                                                                                                                                                            |

## Details

`panel.identify` is similar to `identify`. When called, it waits for the user to identify points (in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure. Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to `trellis.focus` first is necessary.

`panel.link.splom` is meant for use with `spлом`, and requires a panel to be chosen using `trellis.focus` before it is called. Clicking on a point causes that and the corresponding projections in other pairwise scatter plots to be highlighted. `panel.brush.splom` is a (misnamed) alias for `panel.link.splom`, retained for back-compatibility.

`panel.identify.qqmath` is a specialized wrapper meant for use with the display produced by `qqmath`. `panel.identify.cloud` is a specialized wrapper meant for use with the display produced by `cloud`. It would be unusual to call them except in a context where default panel function arguments are available through `trellis.panelArgs` (see below).

One way in which `panel.identify` etc. are different from `identify` is in how it uses the `subscripts` argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel. This information is available to the panel function, but only in certain situations. One way to ensure that `subscripts` is available is to specify `subscripts = TRUE` in the high level call such as `xyplot`. If `subscripts` is not explicitly specified in the call to `panel.identify`, but is available in `panel.args`, then those values will be used. Otherwise, they default to `seq_along(x)`. In either case, the final return value will be the `subscripts` that were marked.

The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

`trellis.focus` can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the name along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, `trellis.focus` will always go to the plot that was created last. For more flexibility, use grid functions directly (see note below).

After a successful call to `trellis.focus`, the desired viewport (typically panel or strip area) will be made the 'current' viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a "trellis" object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last "trellis" object plotted, and is available through `trellis.currentLayout`.

`trellis.unfocus` unsets the focus, and makes the top level viewport the current viewport.

`trellis.switchFocus` is a convenience function to switch from one viewport to another, while preserving the current row and column. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, `trellis.panelArgs` can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

```
trellis.panelArgs()
```

This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the prepanel function). `trellis.panelArgs` can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the `packet.number` (as described under the panel entry in [xyplot](#)) and not the position in the layout, because a layout determines the panel only **after** the object has been printed.

It is usually not necessary to call `trellis.vpname` and `trellis.grobname` directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

## Value

`panel.identify` returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of `identify` with `pos=TRUE` is not yet implemented, but can be considered for addition if requested.

`trellis.panelArgs` returns a named list of arguments that were available to the panel function for the chosen panel.

`trellis.vpname` and `trellis.grobname` return character strings.

`trellis.focus` has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components `col` and `row` giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is `NULL`. If click was outside a panel, both `col` and `row` are set to 0.

**Note**

The viewports created by lattice are accessible to the user through `trellis.focus` as described above. Functions from the `grid` package can also be used directly. For example, `current.vpTree` can be used to inspect the current viewport tree and `seekViewport` or `downViewport` can be used to navigate to these viewports. For such usage, `trellis.vpname` and `trellis.grobname` provides a portable way to access the appropriate viewports and grobs by name.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>. Felix Andrews provided initial implementations of `panel.identify`, `qqmath` and support for focusing on panels interactively.

**Examples**

```
Not run:
xyplot(1:10 ~ 1:10)
trellis.focus("panel", 1, 1)
panel.identify()

End(Not run)

xyplot(Petal.Length ~ Sepal.Length | Species, iris, layout = c(2, 2))
Sys.sleep(1)

trellis.focus("panel", 1, 1)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

trellis.focus("panel", 2, 1)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

trellis.focus("panel", 1, 2)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

choosing loess smoothing parameter

p <- xyplot(dist ~ speed, cars)

panel.loessresid <-
 function(x = panel.args$x,
 y = panel.args$y,
 span,
 panel.args = trellis.panelArgs())
{
 fm <- loess(y ~ x, span = span)
 xgrid <- do.breaks(current.panel.limits()$xlim, 50)
```

```

ygrid <- predict(fm, newdata = data.frame(x = xgrid))
panel.lines(xgrid, ygrid)
pred <- predict(fm)
center residuals so that they fall inside panel
resids <- y - pred + mean(y)
fm.resid <- loess.smooth(x, resids, span = span)
##panel.points(x, resids, col = 1, pch = 4)
panel.lines(fm.resid, col = 1)
}

spans <- c(0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8)
update(p, index.cond = list(rep(1, length(spans))))
panel.locs <- trellis.currentLayout()

i <- 1

for (row in 1:nrow(panel.locs))
 for (column in 1:ncol(panel.locs))
 if (panel.locs[row, column] > 0)
 {
 trellis.focus("panel", row = row, column = column,
 highlight = FALSE)
 panel.loessresid(span = spans[i])
 grid::grid.text(paste("span = ", spans[i]),
 x = 0.25,
 y = 0.75,
 default.units = "npc")

|---------------------------|--------------------------------------------|
| F.1 <i>panel.barchart</i> | <i>Default Panel Function for barchart</i> |
|---------------------------|--------------------------------------------|

---

**Description**

Default panel function for barchart.

**Usage**

```

panel.barchart(x, y, box.ratio = 1, box.width,
 horizontal = TRUE,
 origin = NULL, reference = TRUE,
 stack = FALSE,
 groups = NULL,
 col = if (is.null(groups)) plot.polygon$col
 else superpose.polygon$col,
 border = if (is.null(groups)) plot.polygon$border
 else superpose.polygon$border,
 lty = if (is.null(groups)) plot.polygon$lty
 else superpose.polygon$lty,

```

```
lwd = if (is.null(groups)) plot.polygon$lwd
 else superpose.polygon$lwd,
..., identifier = "barchart")
```

### Arguments

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                     | Extent of Bars. By default, bars start at left of panel, unless origin is specified, in which case they start there.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>y</code>                     | Horizontal location of bars. Possibly a factor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>box.ratio</code>             | Ratio of bar width to inter-bar space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>box.width</code>             | Thickness of bars in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.                                                                                                                                                                                                                                                                                                                    |
| <code>horizontal</code>            | Logical flag. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation.                                                                                                                                                                                                                                          |
| <code>origin</code>                | The origin for the bars. For grouped displays with <code>stack = TRUE</code> , this argument is ignored and the origin set to 0. Otherwise, defaults to <code>NULL</code> , in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, <code>origin = 0</code> is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative). |
| <code>reference</code>             | Logical, whether a reference line is to be drawn at the origin.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>stack</code>                 | logical, relevant when <code>groups</code> is non-null. If <code>FALSE</code> (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.                                                                                                                                                                                                                                                                                                                                                         |
| <code>groups</code>                | Optional grouping variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>col, border, lty, lwd</code> | Graphical parameters for the bars. By default, the trellis parameter <code>plot.polygon</code> is used if there is no grouping variable, otherwise <code>superpose.polygon</code> is used. <code>col</code> gives the fill color, <code>border</code> the border color, and <code>lty</code> and <code>lwd</code> the line type and width of the borders.                                                                                                                                                                                                   |
| <code>...</code>                   | Extra arguments will be accepted but ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>identifier</code>            | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level `barchart` call directly.

F.1 *panel.bwplot**Default Panel Function for bwplot*

---

**Description**

This is the default panel function for *bwplot*.

**Usage**

```
panel.bwplot(x, y, box.ratio = 1,
 box.width = box.ratio / (1 + box.ratio),
 horizontal = TRUE,
 pch, col, alpha, cex,
 font, fontfamily, fontface,
 fill, varwidth = FALSE,
 notch = FALSE, notch.frac = 0.5,
 ...,
 levels.fos,
 stats = boxplot.stats,
 coef = 1.5,
 do.out = TRUE,
 identifier = "bwplot")
```

**Arguments**

|                                                               |                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                                             | numeric vector or factor. Boxplots drawn for each unique value of <code>y</code> ( <code>x</code> ) if <code>horizontal</code> is <code>TRUE</code> ( <code>FALSE</code> )                                                                                                                                    |
| <code>box.ratio</code>                                        | ratio of box thickness to inter box space                                                                                                                                                                                                                                                                     |
| <code>box.width</code>                                        | thickness of box in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.                                                                       |
| <code>horizontal</code>                                       | logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation. |
| <code>pch, col, alpha, cex, font, fontfamily, fontface</code> | graphical parameters controlling the dot. <code>pch=" "</code> is treated specially, by replacing the dot with a line (similar to <a href="#">boxplot</a> )                                                                                                                                                   |
| <code>fill</code>                                             | color to fill the boxplot                                                                                                                                                                                                                                                                                     |
| <code>varwidth</code>                                         | logical. If <code>TRUE</code> , widths of boxplots are proportional to the number of points used in creating it.                                                                                                                                                                                              |

|                           |                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>notch</code>        | if <code>notch</code> is <code>TRUE</code> , a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is ‘strong evidence’ that the two medians differ (Chambers et al., 1983, p. 62). See <a href="#">boxplot.stats</a> for the calculations used.                                                                                                      |
| <code>notch.frac</code>   | numeric in (0,1). When <code>notch=TRUE</code> , the fraction of the box width that the notches should use.                                                                                                                                                                                                                                                                                 |
| <code>stats</code>        | a function, defaulting to <a href="#">boxplot.stats</a> , that accepts a numeric vector and returns a list similar to the return value of <code>boxplot.stats</code> . The function must accept arguments <code>coef</code> and <code>do.out</code> even if they do not use them (a <code>...</code> argument is good enough). This function is used to determine the box and whisker plot. |
| <code>coef, do.out</code> | passed to <code>stats</code>                                                                                                                                                                                                                                                                                                                                                                |
| <code>levels.fos</code>   | numeric values corresponding to positions of the factor or shingle variable. For internal use.                                                                                                                                                                                                                                                                                              |
| <code>...</code>          | further arguments, ignored.                                                                                                                                                                                                                                                                                                                                                                 |
| <code>identifier</code>   | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                         |

### Details

Creates Box and Whisker plot of `x` for every level of `y` (or the other way round if `horizontal=FALSE`). By default, the actual boxplot statistics are calculated using `boxplot.stats`. Note that most arguments controlling the display can be supplied to the high-level `bwplot` call directly.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters ("`box.rectangle`" for the box, "`box.umbrella`" for the whiskers and "`plot.symbol`" for the outliers).

### Examples

```
bwplot(voice.part ~ height, data = singer,
 xlab = "Height (inches)",
 panel = function(...) {
 panel.grid(v = -1, h = 0)
 panel.bwplot(...)
 },
 par.settings = list(plot.symbol = list(pch = 4)))

bwplot(voice.part ~ height, data = singer,
 xlab = "Height (inches)",
 notch = TRUE, pch = "|")
```

**Description**

Default panel functions controlling cloud and wireframe displays.

**Usage**

```

panel.cloud(x, y, subscripts, z,
 groups = NULL,
 perspective = TRUE,
 distance = if (perspective) 0.2 else 0,
 xlim, ylim, zlim,
 panel.3d.cloud = "panel.3dscatter",
 panel.3d.wireframe = "panel.3dwire",
 screen = list(z = 40, x = -60),
 R.mat = diag(4), aspect = c(1, 1),
 par.box = NULL,
 xlab, ylab, zlab,
 xlab.default, ylab.default, zlab.default,
 scales.3d,
 proportion = 0.6,
 wireframe = FALSE,
 scpos,
 ...,
 at,
 identifier = "cloud")
panel.wireframe(...)
panel.3dscatter(x, y, z, rot.mat, distance,
 groups, type = "p",
 xlim, ylim, zlim,
 xlim.scaled, ylim.scaled, zlim.scaled,
 zero.scaled,
 col, col.point, col.line,
 lty, lwd, cex, pch, fill,
 cross, ..., .scale = FALSE, subscripts,
 identifier = "3dscatter")
panel.3dwire(x, y, z, rot.mat = diag(4), distance,
 shade = FALSE,
 shade.colors.palette = trellis.par.get("shade.colors")$palette,
 light.source = c(0, 0, 1000),
 xlim, ylim, zlim,
 xlim.scaled,
 ylim.scaled,
 zlim.scaled,
 col = if (shade) "transparent" else "black",
 lty = 1, lwd = 1,
 alpha,
 col.groups = superpose.polygon$col,
 polynum = 100,

```

```

...,

.drape = FALSE,
.at,
.col.regions = regions$col,
.alpha.regions = regions$alpha,
.identifier = "3dwire")
makeShadePalette(col.regions, ..., min = 0.05, pref = 0.75)

```

## Arguments

|                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y, z</code>                            | <p>numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For <code>panel.cloud</code> these are essentially the same as the data passed to the high level plot (except if formula was a matrix, the appropriate x and y vectors are generated). By the time they are passed to <code>panel.3dscatter</code> and <code>panel.3dwire</code>, they have been appropriately subsetting (using subscripts) and scaled (to lie inside a bounding box, usually the [-0.5, 0.5] cube).</p> <p>Further, for <code>panel.3dwire</code>, x and y are shorter than z and represent the sorted locations defining a rectangular grid. Also in this case, z may be a matrix if the display is grouped, with each column representing one surface.</p> <p>In <code>panel.cloud</code> (called from <code>wireframe</code>) and <code>panel.3dwire</code>, x, y and z could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.</p> |
| <code>subscripts</code>                         | index specifying which points to draw. The same x, y and z values (representing the whole data) are passed to <code>panel.cloud</code> for each panel. <code>subscripts</code> specifies the subset of rows to be used for the particular panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>groups</code>                             | specification of a grouping variable, passed down from the high level functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>perspective</code>                        | logical, whether to plot a perspective view. Setting this to FALSE is equivalent to setting distance to 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>distance</code>                           | numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is 1 / distance. This is described in a little more detail in the documentation for <a href="#">cloud</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>screen</code>                             | A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive z-axis, and the x and y axes in the usual position. Each component of the list should be named one of "x", "y" or "z" (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>R.mat</code>                              | initial rotation matrix in homogeneous coordinates, to be applied to the data before screen rotates the view further.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>par.box</code>                            | graphical parameters for box, namely, col, lty and lwd. By default obtained from the parameter <code>box.3d</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>xlim, ylim, zlim</code>                   | limits for the respective axes. As with other lattice functions, these could each be a numeric 2-vector or a character vector indicating levels of a factor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>panel.3d.cloud, panel.3d.wireframe</code> | functions that draw the data-driven part of the plot (as opposed to the bounding box and scales) in <code>cloud</code> and <code>wireframe</code> . This function is called after the 'back' of the bounding box is drawn, but before the 'front' is drawn.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Any user-defined custom display would probably want to change these functions. The intention is to pass as much information to this function as might be useful (not all of which are used by the defaults). In particular, these functions can expect arguments called `xlim`, `ylim`, `zlim` which give the bounding box ranges in the original data scale and `xlim.scaled`, `ylim.scaled`, `zlim.scaled` which give the bounding box ranges in the transformed scale. More arguments can be considered on request.

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <code>scales.3d</code>                             | list defining the scales                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>proportion</code>                            | numeric scalar, gives the length of arrows as a proportion of the sides                                                                                                                                                                                                                                                                                                                                                          |
| <code>scpos</code>                                 | A list with three components <code>x</code> , <code>y</code> and <code>z</code> (each a scalar integer), describing which of the 12 sides of the cube the scales should be drawn. The defaults should be OK. Valid values are <code>x</code> : 1, 3, 9, 11; <code>y</code> : 8, 5, 7, 6 and <code>z</code> : 4, 2, 10, 12. (See comments in the source code of <code>panel.cloud</code> to see the details of this enumeration.) |
| <code>wireframe</code>                             | logical, indicating whether this is a wireframe plot                                                                                                                                                                                                                                                                                                                                                                             |
| <code>drape</code>                                 | logical, whether the facets will be colored by height, in a manner similar to <code>levelplot</code> . This is ignored if <code>shade=TRUE</code> .                                                                                                                                                                                                                                                                              |
| <code>at</code>                                    | When <code>drape = TRUE</code> in <code>wireframe</code> , the facets defining the surface are colored as a function of (average) height, similar to <code>levelplot</code> . <code>at</code> is a numeric vector giving the breakpoints along the <code>z</code> -axis where colors change.                                                                                                                                     |
| <code>col.regions</code>                           | vector of colors to be used in conjunction with <code>at</code> when <code>drape = TRUE</code> .<br>In <code>makeShadePalette</code> , which can be used to define a shading palette (see below), <code>col.regions</code> is an initial vector defining the base color (as a function of height) that is then adjusted according to irradiance and reflectance.                                                                 |
| <code>alpha.regions</code>                         | numeric scalar controlling transparency when <code>drape = TRUE</code> .                                                                                                                                                                                                                                                                                                                                                         |
| <code>rot.mat</code>                               | 4x4 transformation matrix in homogeneous coordinates. This gives the rotation matrix combining the screen and <code>R.mat</code> arguments to <code>panel.cloud</code>                                                                                                                                                                                                                                                           |
| <code>type</code>                                  | Character vector, specifying type of cloud plot. Can include one or more of "p", "l", "h" or "b". "p" and "l" mean 'points' and 'lines' respectively, and "b" means 'both'. "h" stands for 'histogram', and causes a line to be drawn from each point to the X-Y plane (i.e., the plane representing <code>z = 0</code> ), or the lower (or upper) bounding box face, whichever is closer.                                       |
| <code>xlim.scaled, ylim.scaled, zlim.scaled</code> | axis limits (after being scaled to the bounding box)                                                                                                                                                                                                                                                                                                                                                                             |
| <code>zero.scaled</code>                           | <code>z</code> -axis location (after being scaled to the bounding box) of the X-Y plane in the original data scale, to which lines will be dropped (if within range) from each point when <code>type = "h"</code>                                                                                                                                                                                                                |
| <code>cross</code>                                 | logical, defaults to <code>TRUE</code> if <code>pch = "+"</code> . <code>panel.3dscatter</code> can represent each point by a 3d 'cross' of sorts (it's much easier to understand looking at an example than from a description). This is different from the usual <code>pch</code> argument, and reflects the depth of the points and the orientation of the axes. This argument indicates whether this feature will be used.   |

|                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                        | This is useful for two reasons. It can be set to FALSE to use "+" as the plotting character in the regular sense. It can also be used to force this feature in grouped displays.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>shade</code>                                                     | logical, indicating whether the surface is to be colored using an illumination model with a single light source                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>shade.colors.palette</code>                                      | a function (or the name of one) that is supposed to calculate the color of a facet when shading is being used. Three pieces of information are available to the function: first, the cosine of the angle between the incident light ray and the normal to the surface (representing foreshortening); second, the cosine of half the angle between the reflected ray and the viewing direction (useful for non-Lambertian surfaces); and third, the scaled (average) height of that particular facet with respect to the total plot z-axis limits.<br><br>All three numbers should be between 0 and 1. The <code>shade.colors.palette</code> function should return a valid color. The default function is obtained from the trellis settings using <code>makeShadePalette</code> . |
| <code>min</code>                                                       | numeric, between 0 and 1, giving a minimum saturation in <code>makeShadePalette</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>pref</code>                                                      | numeric, giving a power that is applied to reflectance value before it is used to 'darken' the colors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>light.source</code>                                              | a 3-vector representing (in cartesian coordinates) the light source. This is relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis), keeping in mind that all observations are bounded within the [-0.5, 0.5] cube                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>polynum</code>                                                   | quadrilateral faces are drawn in batches of <code>polynum</code> at a time. Drawing too few at a time increases the total number of calls to the underlying <code>grid.polygon</code> function, which affects speed. Trying to draw too many at once may be unnecessarily memory intensive. This argument controls the trade-off.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>col.groups</code>                                                | colors for different groups                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>col, col.point, col.line, lty, lwd, cex, pch, fill, alpha</code> | Graphical parameters. | <code>...</code>                                                       | other parameters, passed down when appropriate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>.scale</code>                                                    | Logical flag, indicating whether x, y, and z should be assumed to be in the original data scale and hence scaled before being plotted. x, y, and z are usually already scaled. However, setting <code>.scale=TRUE</code> may be helpful for calls to <code>panel.3dscatter</code> and <code>panel.3dwire</code> in user-supplied panel functions.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>identifier</code>                                                | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Details

These functions together are responsible for the content drawn inside each panel in `cloud` and `wireframe`. `panel.wireframe` is a wrapper to `panel.cloud`, which does the actual work.

`panel.cloud` is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether `wireframe` is TRUE, it calls either `panel.3d.wireframe` or `panel.3d.cloud`, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For `cloud`, the data is unstructured, and x, y and z are all passed to the `panel.3d.cloud` function. For `wireframe`, on the other hand, x and y are increasing vectors with unique values,

defining a rectangular grid. `z` must be a matrix with `length(x) * length(y)` rows, and as many columns as the number of groups.

`panel.3dscatter` is the default `panel.3d.cloud` function. It has a `type` argument similar to [panel.xyplot](#), and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)

`panel.3dwire` is the default `panel.3d.wireframe` function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about polygon facets, and draws them all at once. This avoids the overhead of drawing `grid.polygon` repeatedly, speeding up the rendering considerably. If `shade = TRUE`, these attempt to color the surface as being illuminated from a light source at `light.source`. `palette.shade` is a simple function that provides the default shading colors

Multiple surfaces are drawn if `groups` is non-null in the call to `wireframe`, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

F.1 *panel.densityplot*    *Default Panel Function for densityplot*

---

### Description

This is the default panel function for [densityplot](#).

### Usage

```
panel.densityplot(x, darg, plot.points = "jitter",
 ref = FALSE,
 groups = NULL,
 weights = NULL,
 jitter.amount,
 type, ...,
 grid = lattice.getOption("default.args")$grid,
 identifier = "density")
```

**Arguments**

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | data points for which density is to be estimated                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>darg</code>          | list of arguments to be passed to the <a href="#">density</a> function. Typically, this should be a list with zero or more of the following components : <code>bw</code> , <code>adjust</code> , <code>kernel</code> , <code>window</code> , <code>width</code> , <code>give.Rkern</code> , <code>n</code> , <code>from</code> , <code>to</code> , <code>cut</code> , <code>na.rm</code> (see <a href="#">density</a> for details)                                                                                                                                                                      |
| <code>plot.points</code>   | logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are <code>"rug"</code> , in which case <a href="#">panel.rug</a> is used to plot a ‘rug’, and <code>"jitter"</code> , in which case the points are jittered vertically to better distinguish overlapping points.                                                                                                                                                                                 |
| <code>ref</code>           | logical, whether to draw x-axis                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>groups</code>        | an optional grouping variable. If present, <a href="#">panel.superpose</a> will be used instead to display each subgroup                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>weights</code>       | numeric vector of weights for the density calculations. If this is specified, the ... part must also include a <code>subscripts</code> argument that matches the weights to <code>x</code> .                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>jitter.amount</code> | when <code>plot.points="jitter"</code> , the value to use as the <code>amount</code> argument to <a href="#">jitter</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>type</code>          | type argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a <code>type</code> argument, if specified, from affecting the density curve.                                                                                                                                                                                                                                                                                                                                                                                                     |
| ...                        | extra graphical parameters. Note that additional arguments to <a href="#">panel.rug</a> cannot be passed on through <code>panel.densityplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>grid</code>          | <p>A logical flag, character string, or list specifying whether and how a background grid should be drawn. In its general form, <code>grid</code> can be a list of arguments to be supplied to <a href="#">panel.grid</a>, which is called with those arguments. Three shortcuts are available:</p> <p><code>TRUE</code>: roughly equivalent to <code>list(h = -1, v = -1)</code><br/> <code>"h"</code>: roughly equivalent to <code>list(h = -1, v = 0)</code><br/> <code>"v"</code>: roughly equivalent to <code>list(h = 0, v = -1)</code></p> <p>No grid is drawn if <code>grid = FALSE</code>.</p> |
| <code>identifier</code>    | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

F.1 *panel.dotplot*      *Default Panel Function for dotplot*

---

**Description**

Default panel function for dotplot.

**Usage**

```
panel.dotplot(x, y, horizontal = TRUE,
 pch, col, lty, lwd, col.line,
 levels.fos,
 groups = NULL,
 ...,
 grid = lattice.getOption("default.args")$grid,
 identifier = "dotplot")
```

**Arguments**

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                         | variables to be plotted in the panel. Typically <code>y</code> is the ‘factor’                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>horizontal</code>                   | logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation.                                                                                                                                                                                                                                                                                                                                                    |
| <code>pch, col, lty, lwd, col.line</code> | graphical parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>levels.fos</code>                   | locations where reference lines will be drawn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>groups</code>                       | grouping variable (affects graphical parameters)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>...</code>                          | extra parameters, passed to <code>panel.xyplot</code> which is responsible for drawing the foreground points ( <code>panel.dotplot</code> only draws the background reference lines).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>grid</code>                         | A logical flag, or list specifying whether and how a background grid should be drawn. In its general form <code>grid</code> can be a list of arguments to be supplied to <a href="#">panel.grid</a> , which is called with those arguments. If <code>FALSE</code> , no grid lines are drawn. <code>grid = TRUE</code> is roughly equivalent to <code>list(h = 0, v = -1)</code> if <code>horizontal = TRUE</code> and <code>list(h = -1, v = 0)</code> if <code>horizontal = FALSE</code> . In other words, grid lines are drawn only for the numeric axis, as reference lines for the categorical axis are drawn regardless of the value of <code>grid</code> . |
| <code>identifier</code>                   | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Details**

Creates (possibly grouped) Dotplot of `x` against `y` or vice versa

---

F.1 *panel.histogram*      *Default Panel Function for histogram*

---

**Description**

This is the default panel function for histogram.

**Usage**

```
panel.histogram(x,
 breaks,
 equal.widths = TRUE,
 type = "density",
 nint = round(log2(length(x)) + 1),
 alpha, col, border, lty, lwd,
 ...,
 identifier = "histogram")
```

**Arguments**

|                                           |                                                                                                     |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>x</code>                            | The data points for which the histogram is to be drawn                                              |
| <code>breaks</code>                       | The breakpoints for the histogram                                                                   |
| <code>equal.widths</code>                 | logical used when <code>breaks==NULL</code>                                                         |
| <code>type</code>                         | Type of histogram, possible values being "percent", "density" and "count"                           |
| <code>nint</code>                         | Number of bins for the histogram                                                                    |
| <code>alpha, col, border, lty, lwd</code> | graphical parameters for bars; defaults are obtained from the <code>plot.polygon</code> settings.   |
| <code>...</code>                          | other arguments, passed to <a href="#">hist</a> when deemed appropriate                             |
| <code>identifier</code>                   | A character string that is prepended to the names of grobs that are created by this panel function. |

---

**Description**

These are the default panel functions for [levelplot](#) and [contourplot](#). Also documented is an alternative raster-based panel function for use with [levelplot](#).

**Usage**

```
panel.levelplot(x, y, z,
 subscripts,
 at = pretty(z),
 shrink,
 labels,
 label.style = c("mixed", "flat", "align"),
 contour = FALSE,
 region = TRUE,
 col = add.line$col,
 lty = add.line$lty,
 lwd = add.line$lwd,
 border = "transparent",
 border.lty = 1,
 border.lwd = 0.1,
 ...,
 region.type = c("grid", "contour"),
 col.regions = regions$col,
 alpha.regions = regions$alpha,
 identifier = "levelplot")
panel.contourplot(...)

panel.levelplot.raster(x, y, z,
 subscripts,
 at = pretty(z),
 ...,
 col.regions = regions$col,
 alpha.regions = regions$alpha,
 interpolate = FALSE,
 identifier = "levelplot")
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y, z</code>    | Variables defining the plot.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>subscripts</code> | Integer vector indicating what subset of <code>x</code> , <code>y</code> and <code>z</code> to draw.                                                                                                                                                                                                                                                                                                                              |
| <code>at</code>         | Numeric vector giving breakpoints along the range of <code>z</code> . See <a href="#">levelplot</a> for details.                                                                                                                                                                                                                                                                                                                  |
| <code>shrink</code>     | Either a numeric vector of length 2 (meant to work as both <code>x</code> and <code>y</code> components), or a list with components <code>x</code> and <code>y</code> which are numeric vectors of length 2. This allows the rectangles to be scaled proportional to the <code>z</code> -value. The specification can be made separately for widths ( <code>x</code> ) and heights ( <code>y</code> ). The elements of the length |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of z).                                                                                                                                                                                                                                                                                                                                                                                                                  |
| labels                 | <p>Either a logical scalar indicating whether the labels are to be drawn, or a character or expression vector giving the labels associated with the at values. Alternatively, labels can be a list with the following components:</p> <p>labels: a character or expression vector giving the labels. This can be omitted, in which case the defaults will be used.</p> <p>col, cex, alpha: graphical parameters for label texts</p> <p>fontfamily, fontface, font: font used for the labels</p>                              |
| label.style            | Controls how label positions and rotation are determined. A value of "flat" causes the label to be positioned where the contour is flattest, and the label is not rotated. A value of "align" causes the label to be drawn as far from the boundaries as possible, and the label is rotated to align with the contour at that point. The default is to mix these approaches, preferring the flattest location unless it is too close to the boundaries.                                                                      |
| contour                | A logical flag, specifying whether contour lines should be drawn.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| region                 | A logical flag, specifying whether inter-contour regions should be filled with appropriately colored rectangles.                                                                                                                                                                                                                                                                                                                                                                                                             |
| col, lty, lwd          | Graphical parameters for contour lines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| border                 | Border color for rectangles used when region=TRUE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| border.lty, border.lwd | Graphical parameters for the border                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ...                    | Extra parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| region.type            | <p>A character string, one of "grid" and "contour". The former (the default) uses a grid of rectangles to display the colors for the level plot; the latter uses a grid of polygons, mimicking the behavior of <a href="#">filled.contour</a>, which gives a smoother appearance at the cost of increased processing time.</p> <p>The "contour" option requires x and y to be complete, in the sense that it must include all possible combinations in the underlying grid. However, z values are allowed to be missing.</p> |
| col.regions            | A vector of colors, or a function to produce a vector of colors, to be used if region=TRUE. Each interval defined by at is assigned a color, so the number of colors actually used is one less than the length of at. See <a href="#">level.colors</a> for details on how the color assignment is done.                                                                                                                                                                                                                      |
| alpha.regions          | numeric scalar controlling transparency of facets                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| interpolate            | logical, passed to <a href="#">grid.raster</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| identifier             | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

The same panel function is used for both `levelplot` and `contourplot` (which differ only in default values of some arguments). `panel.contourplot` is a simple wrapper to `panel.levelplot`.

When `contour=TRUE`, the `contourLines` function is used to calculate the contour lines.

`panel.levelplot.raster` is an alternative panel function that uses the raster drawing abilities in R 2.11.0 and higher (through [grid.raster](#)). It has fewer options (e.g., can only render data on an equispaced grid), but can be more efficient. When using `panel.levelplot.raster`, it may be desirable to render the color key in the same way. This is possible, but must be done separately; see [levelplot](#) for details.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>.

The functionality of `region.type = "contour"` is based on code borrowed from the **gridGraphics** package, written by Zhijian (Jason) Wen and Paul Murrell and ported to lattice by Johan Larsson.

**Examples**

```
require(grid)

levelplot(rnorm(10) ~ 1:10 + sort(runif(10)), panel = panel.levelplot)

suppressWarnings(plot(levelplot(rnorm(10) ~ 1:10 + sort(runif(10))),
 panel = panel.levelplot.raster,
 interpolate = TRUE)))

levelplot(volcano, panel = panel.levelplot.raster)

levelplot(volcano, panel = panel.levelplot.raster,
 col.regions = hcl.colors, cuts = 30, interpolate = TRUE)
```

---

*Default Superpanel Function for splom*

---

**Description**

This is the default superpanel function for *splom*.

**Usage**

```
panel.pairs(z,
 panel = lattice.getOption("panel.splom"),
 lower.panel = panel,
 upper.panel = panel,
 diag.panel = "diag.panel.splom",
 as.matrix = FALSE,
 groups = NULL,
 panel.subscripts,
 subscripts,
 pscales = 5,
 prepanel.limits = scale_limits,
 varnames = colnames(z),
 varname.col, varname.cex, varname.font,
 varname.fontfamily, varname.fontface,
 axis.text.col, axis.text.cex, axis.text.font,
 axis.text.fontfamily, axis.text.fontface,
 axis.text.lineheight,
 axis.line.col, axis.line.lty, axis.line.lwd,
```

```

axis.line.alpha, axis.line.tck,
...)
diag.panel.splom(x = NULL,
 varname = NULL, limits, at = NULL, labels = NULL,
 draw = TRUE, tick.number = 5,
 varname.col, varname.cex,
 varname.lineheight, varname.font,
 varname.fontfamily, varname.fontface,
 axis.text.col, axis.text.alpha,
 axis.text.cex, axis.text.font,
 axis.text.fontfamily, axis.text.fontface,
 axis.text.lineheight,
 axis.line.col, axis.line.alpha,
 axis.line.lty, axis.line.lwd,
 axis.line.tck,
 ...)

```

### Arguments

|                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>z</code>                               | The data frame used for the plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>panel, lower.panel, upper.panel</code> | The panel function used to display each pair of variables. If specified, <code>lower.panel</code> and <code>upper.panel</code> are used for panels below and above the diagonal respectively.<br><br>In addition to extra arguments not recognized by <code>panel.pairs</code> , the list of arguments passed to the panel function also includes arguments named <code>i</code> and <code>j</code> , with values indicating the row and column of the scatterplot matrix being plotted.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>diag.panel</code>                      | The panel function used for the diagonals. See arguments to <code>diag.panel.splom</code> to know what arguments this function is passed when called. Use <code>diag.panel=NULL</code> to suppress plotting on the diagonal panels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>as.matrix</code>                       | logical. If TRUE, the layout of the panels will have origin on the top left instead of bottom left (similar to <code>pairs</code> ). This is in essence the same functionality as provided by <code>as.table</code> for the panel layout                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>groups</code>                          | Grouping variable, if any                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>panel.subscripts</code>                | logical specifying whether the panel function accepts an argument named <code>subscripts</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>subscripts</code>                      | The indices of the rows of <code>z</code> that are to be displayed in this (super)panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>pscales</code>                         | Controls axis labels, passed down from <code>splom</code> . If <code>pscales</code> is a single number, it indicates the approximate number of equally-spaced ticks that should appear on each axis. If <code>pscales</code> is a list, it should have one component for each column in <code>z</code> , each of which itself a list with the following valid components:<br><code>at</code> : a numeric vector specifying tick locations<br><code>labels</code> : character vector labels to go with <code>at</code><br><code>limits</code> : numeric 2-vector specifying axis limits (should be made more flexible at some point to handle factors)<br>These are specifications on a per-variable basis, and used on all four sides in the diagonal cells used for labelling. Factor variables are labelled with the factor names. Use <code>pscales=0</code> to suppress the axes entirely. |

**prepanel.limits**

A function to calculate suitable axis limits given a single argument `x` containing a data vector. The return value of the function should be similar to the `xlim` or `ylim` argument documented in [xyplot](#); that is, it should be a numeric or `DateTime` vector of length 2 defining a range, or a character vector representing levels of a factor.

Most high-level lattice plots (such as `xyplot`) use the `prepanel` function for deciding on axis limits from data. This function serves a similar function by calculating the per-variable limits. These limits can be overridden by the corresponding `limits` component in the `pscales` list.

|                                                                                                   |                                                                                                                                                                                                                             |
|---------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                                                                                    | data vector corresponding to that row / column (which will be the same for diagonal ‘panels’).                                                                                                                              |
| <code>varname</code>                                                                              | (scalar) character string or expression that is to be written centred within the panel                                                                                                                                      |
| <code>limits</code>                                                                               | numeric of length 2, or, vector of characters, specifying the scale for that panel (used to calculate tick locations when missing)                                                                                          |
| <code>at</code>                                                                                   | locations of tick marks                                                                                                                                                                                                     |
| <code>labels</code>                                                                               | optional labels for tick marks                                                                                                                                                                                              |
| <code>draw</code>                                                                                 | A logical flag specifying whether to draw the tick marks and labels. If <code>FALSE</code> , variable names are shown but axis annotation is omitted.                                                                       |

| <code>axis.line.col</code>                                                                        | Color for the axes.                                                                                                                                                                                                         |
| <code>axis.line.lty</code>                                                                        | Line type for the axes.                                                                                                                                                                                                     |
| <code>axis.line.lwd</code>                                                                        | Line width for the axes.                                                                                                                                                                                                    |
| <code>axis.line.alpha</code>                                                                      | Alpha-transparency for the axes.                                                                                                                                                                                            |
| <code>axis.line.tck</code>                                                                        | A numeric multiplier for the length of tick marks in diagonal panels.                                                                                                                                                       |
| <code>...</code>                                                                                  | Further arguments, passed on to <code>panel</code> , <code>lower.panel</code> , <code>upper.panel</code> , and <code>diag.panel</code> from <code>panel.pairs</code> . Currently ignored by <code>diag.panel.splom</code> . |

**Details**

`panel.pairs` is the function that is actually used as the panel function in a "trellis" object produced by `splom`.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

[splom](#)

**Examples**

```
Cmat <- outer(1:6,1:6,
 function(i,j) hcl.colors(11)[i+j-1]) ## rainbow(11, start=.12, end=.5)[i+j-1])

splom(~diag(6), as.matrix = TRUE,
 panel = function(x, y, i, j, ...) {
 panel.fill(Cmat[i,j])
 panel.text(.5,.5, paste("(",i,"",j,")",sep=""))
 })
```

---

F.1 `panel.parallel`      *Default Panel Function for parallel*

---

**Description**

This is the default panel function for `parallel`.

**Usage**

```
panel.parallel(x, y, z, subscripts,
 groups = NULL,
 col, lwd, lty, alpha,
 common.scale = FALSE,
 lower,
 upper,
 ...,
 horizontal.axis = TRUE,
 identifier = "parallel")
```

**Arguments**

|                         |                                                                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | dummy variables, ignored.                                                                                                                                                                   |
| <code>z</code>          | The data frame used for the plot. Each column will be coerced to numeric before being plotted, and an error will be issued if this fails.                                                   |
| <code>subscripts</code> | The indices of the rows of <code>z</code> that are to be displayed in this panel.                                                                                                           |
| <code>groups</code>     | An optional grouping variable. If specified, different groups are distinguished by use of different graphical parameters (i.e., rows of <code>z</code> in the same group share parameters). |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>col, lwd, lty, alpha</code> | graphical parameters (defaults to the settings for <code>superpose.line</code> ). If <code>groups</code> is non-null, these parameters used one for each group. Otherwise, they are recycled and used to distinguish between rows of the data frame <code>z</code> .                                                                                                            |
| <code>common.scale</code>         | logical, whether a common scale should be used columns of <code>z</code> . Defaults to <code>FALSE</code> , in which case the horizontal range for each column is different (as determined by <code>lower</code> and <code>upper</code> ).                                                                                                                                      |
| <code>lower, upper</code>         | numeric vectors replicated to be as long as the number of columns in <code>z</code> . Determines the lower and upper bounds to be used for scaling the corresponding columns of <code>z</code> after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar. |
| <code>...</code>                  | other arguments (ignored)                                                                                                                                                                                                                                                                                                                                                       |
| <code>horizontal.axis</code>      | logical indicating whether the parallel axes should be laid out horizontally ( <code>TRUE</code> ) or vertically ( <code>FALSE</code> ).                                                                                                                                                                                                                                        |
| <code>identifier</code>           | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                             |

### Details

Produces parallel coordinate plots, which are easier to understand from an example than through a verbal description. See example for [parallel](#)

F.1 `panel.qqmath`

*Default Panel Function for qqmath*

---

### Description

This is the default panel function for `qqmath`.

### Usage

```
panel.qqmath(x, f.value = NULL,
 distribution = qnorm,
 qtype = 7,
 groups = NULL, ...,
 tails.n = 0,
 identifier = "qqmath")
```

**Arguments**

|                                    |                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                     | vector (typically numeric, coerced if not) of data values to be used in the panel.                                                                                                                                                                                                                                                    |
| <code>f.value, distribution</code> | Defines how quantiles are calculated. See <a href="#">qqmath</a> for details.                                                                                                                                                                                                                                                         |
| <code>qtype</code>                 | The type argument to be used in <a href="#">quantile</a>                                                                                                                                                                                                                                                                              |
| <code>groups</code>                | An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters.                                                                                                                                                               |
| <code>...</code>                   | Further arguments, often graphical parameters, eventually passed on to <a href="#">panel.xyplot</a> . Arguments <code>grid</code> and <code>abline</code> of <code>panel.xyplot</code> may be particularly useful.                                                                                                                    |
| <code>tails.n</code>               | number of data points to represent exactly on each tail of the distribution. This reproduces the effect of <code>f.value = NULL</code> for the extreme data values, while approximating the remaining data. It has no effect if <code>f.value = NULL</code> . If <code>tails.n</code> is given, <code>qtype</code> is forced to be 1. |
| <code>identifier</code>            | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                   |

**Details**

Creates a Q-Q plot of the data and the theoretical distribution given by `distribution`. Note that most of the arguments controlling the display can be supplied directly to the high-level `qqmath` call.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

```
set.seed(0)
xx <- rt(10000, df = 10)
qqmath(~ xx, pch = "+", distribution = qnorm,
 grid = TRUE, abline = c(0, 1),
 xlab.top = c("raw", "ppoints(100)", "tails.n = 50"),
 panel = function(..., f.value) {
 switch(panel.number(),
 panel.qqmath(..., f.value = NULL),
 panel.qqmath(..., f.value = ppoints(100)),
 panel.qqmath(..., f.value = ppoints(100), tails.n = 50))
 }, layout = c(3, 1))[c(1,1,1)]
```

---

F.1 *panel.stripplot*      *Default Panel Function for stripplot*

---

**Description**

This is the default panel function for `stripplot`. Also see `panel.superpose`

**Usage**

```
panel.stripplot(x, y, jitter.data = FALSE,
 factor = 0.5, amount = NULL,
 horizontal = TRUE, groups = NULL,
 ...,
 grid = lattice.getOption("default.args")$grid,
 identifier = "stripplot")
```

**Arguments**

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>           | coordinates of points to be plotted                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>jitter.data</code>    | whether points should be jittered to avoid overplotting. The actual jittering is performed inside <code>panel.xyplot</code> , using its <code>jitter.x</code> or <code>jitter.y</code> argument (depending on the value of <code>horizontal</code> ).                                                                                                                                                                                                                                                                                                                                          |
| <code>factor, amount</code> | amount of jittering, see <code>jitter</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>horizontal</code>     | logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation.                                                                                                                                                                                                                                                                                     |
| <code>groups</code>         | optional grouping variable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>...</code>            | additional arguments, passed on to <code>panel.xyplot</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>grid</code>           | A logical flag, character string, or list specifying whether and how a background grid should be drawn. In its general form, <code>grid</code> can be a list of arguments to be supplied to <code>panel.grid</code> , which is called with those arguments. Three shortcuts are available:<br><br><code>TRUE</code> : roughly equivalent to <code>list(h = -1, v = -1)</code><br><code>"h"</code> : roughly equivalent to <code>list(h = -1, v = 0)</code><br><code>"v"</code> : roughly equivalent to <code>list(h = 0, v = -1)</code><br><br>No grid is drawn if <code>grid = FALSE</code> . |
| <code>identifier</code>     | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Details**

Creates `stripplot` (one dimensional scatterplot) of `x` for each level of `y` (or vice versa, depending on the value of `horizontal`)

F.1 *panel.xyplot**Default Panel Function for xyplot***Description**

This is the default panel function for `xyplot`. Also see `panel.superpose`. The default panel functions for `splom` and `qq` are essentially the same function.

**Usage**

```
panel.xyplot(x, y, type = "p",
 groups = NULL,
 pch, col, col.line, col.symbol,
 font, fontfamily, fontface,
 lty, cex, fill, lwd,
 horizontal = FALSE, ...,
 smooth = NULL,
 grid = lattice.getOption("default.args")$grid,
 abline = NULL,
 jitter.x = FALSE, jitter.y = FALSE,
 factor = 0.5, amount = NULL,
 identifier = "xyplot")
panel.splom(..., identifier = "splom")
panel.qq(..., identifier = "qq")
```

**Arguments**

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <code>x, y</code> | variables to be plotted in the scatterplot                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>type</code> | <p>character vector controlling how <code>x</code> and <code>y</code> are to be plotted. Can consist of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "g", "r", "a", "smooth", and "spline". If <code>type</code> has more than one element, an attempt is made to combine the effect of each of the components.</p> <p>The behaviour if any of the first five are included in <code>type</code> is similar to the effect of the corresponding type in <code>plot</code>: "p" and "l" stand for points and lines respectively; "b" and "o" (for 'overlay') plot both; "h" draws vertical (or horizontal if <code>horizontal = TRUE</code>) line segments from the points to the origin. Types "s" and "S" are like "l" in the sense that they join consecutive points, but instead of being joined by a straight line, points are connected by a vertical and a horizontal segment forming a 'step', with the vertical segment coming first for "s", and the horizontal segment coming first for "S". Types "s" and "S" sort the values along one of the axes (depending on <code>horizontal</code>); this is unlike the behavior in <code>plot</code>. For the latter behavior, use <code>type = "s"</code> with <code>panel = panel.points</code>.</p> <p>Type "g" adds a reference grid using <code>panel.grid</code> in the background, but using the <code>grid</code> argument is now the preferred way to do so.</p> |

The remaining values of `type` lead to various types of smoothing. This can also be achieved using the `smooth` argument, or by calling the relevant panel functions directly. The panel functions provide finer control over graphical and other parameters, but using `smooth` or `type` is convenient for simple usage. Using `smooth` is recommended, but `type` is also supported for backwards compatibility.

Type `"r"` adds a linear regression line, `"smooth"` adds a loess fit, `"spline"` adds a cubic smoothing spline fit, and `"a"` draws line segments joining the average `y` value for each distinct `x` value. See `smooth` for details.

See `example(xyplot)` and `demo(lattice)` for examples.

| <code>horizontal</code>                                                                       | A logical flag controlling the orientation for certain type's, e.g., <code>"h"</code> , <code>"s"</code> , and <code>"S"</code> and the result of smoothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>...</code>                                                                              | Extra arguments, if any, for <code>panel.xyplot</code> . Usually passed on as graphical parameters to low level plotting functions, or to the panel functions performing smoothing, if applicable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>smooth</code>                                                                           | <p>If specified, indicates the type of smooth to be added. Can be a character vector containing one or more values from <code>"lm"</code>, <code>"loess"</code>, <code>"spline"</code>, and <code>"average"</code>. Can also be a logical flag; TRUE is interpreted as <code>"loess"</code>. Each of these result in calling a corresponding panel function as described below; the <code>smooth</code> argument simply provides a convenient shortcut.</p> <p><code>"lm"</code> adds a linear regression line (same as <code>panel.lmline</code>, except for default graphical parameters). <code>"loess"</code> adds a loess fit (same as <code>panel.loess</code>). <code>"spline"</code> adds a cubic smoothing spline fit (same as <code>panel.spline</code>). <code>"average"</code> has the effect of calling <code>panel.average</code>, which in conjunction with a <code>groups</code> argument can be useful for creating interaction plots.</p> <p>Normally, smoothing is performed with the <code>y</code> variable as the response and the <code>x</code> variable as the predictor. However, the roles of <code>x</code> and <code>y</code> are reversed if <code>horizontal = TRUE</code>.</p> |
| <code>grid</code>                                                                             | <p>A logical flag, character string, or list specifying whether and how a background grid should be drawn. This provides the same functionality as <code>type="g"</code>, but is the preferred alternative as the effect <code>type="g"</code> is conceptually different from that of other type values (which are all data-dependent). Using the <code>grid</code> argument also allows more flexibility.</p> <p>Most generally, <code>grid</code> can be a list of arguments to be supplied to <code>panel.grid</code>, which is called with those arguments. Three shortcuts are available:</p> <p><code>TRUE</code>: roughly equivalent to <code>list(h = -1, v = -1)</code></p> <p><code>"h"</code>: roughly equivalent to <code>list(h = -1, v = 0)</code></p> <p><code>"v"</code>: roughly equivalent to <code>list(h = 0, v = -1)</code></p> <p>No grid is drawn if <code>grid = FALSE</code>.</p>                                                                                                                                                                                                                                                                                                     |

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>abline</code>             | A numeric vector or more generally a list containing arguments that are used to call <code>panel.abline</code> . If specified as a numeric vector, <code>abline</code> is used as the first unnamed argument to <code>panel.abline</code> . This allows arguments of the form <code>abline = c(0, 1)</code> , which adds the diagonal line, or <code>abline = coef(fm)</code> to fit the regression line from a fitted mode. Use the list form for finer control; e.g., <code>abline = list(h = 0, v = 0, col = "grey")</code> .<br>For more flexibility, use <code>panel.abline</code> directly. |
| <code>jitter.x, jitter.y</code> | logical, whether the data should be jittered before being plotted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>factor, amount</code>     | controls amount of jittering.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>identifier</code>         | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### Details

Creates scatterplot of `x` and `y`, with various modifications possible via the `type` argument. `panel.qq` draws a 45 degree line before calling `panel.xyplot`.

Note that most of the arguments controlling the display can be supplied directly to the high-level (e.g. `xyplot`) call.

F.2 llines

---

*Replacements of traditional graphics functions*

---

### Description

These functions are intended to replace common low level traditional graphics functions, primarily for use in panel functions. The originals can not be used (at least not easily) because lattice panel functions need to use grid graphics. Low level drawing functions in grid can be used directly as well, and is often more flexible. These functions are provided for convenience and portability.

### Usage

```

lplot.xy(xy, type, pch, lty, col, cex, lwd,
 font, fontfamily, fontface,
 col.line, col.symbol, alpha, fill,
 origin = 0, ..., identifier, name.type)

larrows(...)
llines(x, ...)
lpoints(x, ...)
lpolygon(x, ...)
lpolypath(x, ...)
lrect(...)
lsegments(...)
ltext(x, ...)

Default S3 method:
larrows(x0 = NULL, y0 = NULL, x1, y1, x2 = NULL, y2 = NULL,
 angle = 30, code = 2, length = 0.25, unit = "inches",
 ends = switch(code, "first", "last", "both"),
 type = "open",
 col = add.line$col,
 alpha = add.line$alpha,
 lty = add.line$lty,
 lwd = add.line$lwd,
 fill = NULL,
 font, fontface,
 ..., identifier, name.type)

Default S3 method:
llines(x, y = NULL, type = "l",
 col, alpha, lty, lwd, ..., identifier, name.type)

Default S3 method:
lpoints(x, y = NULL, type = "p", col, pch, alpha, fill,

```

```

 font, fontfamily, fontface, cex, ..., identifier, name.type)
Default S3 method:
lpolygon(x, y = NULL,
 border = "black", col = "transparent", fill = NULL,
 font, fontface,
 ...,
 rule = c("none", "winding", "evenodd"),
 identifier, name.type)
Default S3 method:
lpolypath(x, y = NULL,
 border = "black", col = "transparent", fill = NULL,
 font, fontface,
 ...,
 rule = c("winding", "evenodd"),
 identifier, name.type)
Default S3 method:
ltext(x, y = NULL, labels = seq_along(x),
 col, alpha, cex, srt = 0,
 lineheight, font, fontfamily, fontface,
 adj = c(0.5, 0.5), pos = NULL, offset = 0.5, ..., identifier, name.type)
Default S3 method:
lrect(xleft, ybottom, xright, ytop,
 x = (xleft + xright) / 2,
 y = (ybottom + ytop) / 2,
 width = xright - xleft,
 height = ytop - ybottom,
 col = "transparent",
 border = "black",
 lty = 1, lwd = 1, alpha = 1,
 just = "center",
 hjust = NULL, vjust = NULL,
 font, fontface,
 ..., identifier, name.type)
Default S3 method:
lsegments(x0, y0, x1, y1, x2, y2,
 col, alpha, lty, lwd,
 font, fontface, ..., identifier, name.type)

panel.arrows(...)
panel.lines(...)
panel.points(...)
panel.polygon(...)
panel.rect(...)
panel.segments(...)
panel.text(...)

```

### Arguments

`x, y, x0, y0, x1, y1, x2, y2, xy` locations. `x2` and `y2` are available for for S compatibility.

`length, unit` determines extent of arrow head. `length` specifies the length in terms of `unit`, which can be any valid grid unit as long as it doesn't need a data argument. `unit`

|                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| rule                                                                                                       | character string specifying how NA values are interpreted for polygons and paths. This is mainly intended for paths (via <a href="#">grid.path</a> ), but can also be specified for polygons for convenience.<br>For polygons, the default rule is "none", which treats NA-separated segments as separate polygons. This value is only valid for polygons. For the other rules ("winding" or "evenodd") these segments are interpreted as subpaths, possibly representing holes, of a single path, and are rendered using <a href="#">grid.path</a> . Support and rendering speed may depend on the device being used.                                                                        |
| identifier                                                                                                 | A character string that is prepended to the name of the grob that is created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| name.type                                                                                                  | A character value indicating whether the name of the grob should have panel or strip information added to it. Typically either "panel", "strip", "strip.left", or "" (for no extra information).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### Details

These functions are meant to be grid replacements of the corresponding base R graphics functions, to allow existing Trellis code to be used with minimal modification. The functions `panel.*` are essentially identical to the `l*` versions, are recommended for use in new code (as opposed to ported code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All these correspond to the default methods only.

### Note

There is a new `type="H"` option wherever appropriate, which is similar to `type="h"`, but with horizontal lines.

**Examples**

```
SD <- 0.1
t <- seq(0, 2*pi, length.out = 50) + rnorm(50, sd = SD)
d <- list(x = c(cos(t), NA, rev(0.5 * cos(t))) + rnorm(101, sd = SD),
 y = c(sin(t), NA, rev(0.5 * sin(t))) + rnorm(101, sd = SD))

rectangles
xyplot(y ~ x, d, panel = panel.rect, col = 4, alpha = 0.5, width = 0.1, height = 0.1)

points and lines
xyplot(y ~ x, d, panel = panel.lines, col = 4, alpha = 0.5,
 type = "o", pch = 16)

polygons and paths (with holes)
xyplot(y ~ x, d, panel = panel.polygon, col = 4, alpha = 0.5, rule = "evenodd")

Example adapted from https://journal.r-project.org/articles/RJ-2012-017/
x <- c(.1, .5, .9, NA, .4, .5, .6, NA, .4, .6, .5)
y <- c(.1, .8, .1, NA, .5, .4, .5, NA, .3, .3, .2)
d <- data.frame(x = x, y = y)
xyplot(y ~ x, data = d, panel = panel.polygon, rule = "none", col = "grey")
xyplot(y ~ x, data = d, panel = panel.polypath, rule = "winding", col = "grey")
xyplot(y ~ x, data = d, panel = panel.polypath, rule = "evenodd", col = "grey")
```

F.2 *panel.functions*      *Useful Panel Function Components*

---

**Description**

These are predefined panel functions available in lattice for use in constructing new panel functions (often on-the-fly).

**Usage**

```
panel.abline(a = NULL, b = 0,
 h = NULL, v = NULL,
 reg = NULL, coef = NULL,
 col, col.line, lty, lwd, alpha, type,
 ...,
 reference = FALSE,
 identifier = "abline")
panel.refline(...)
```

```

panel.curve(expr, from, to, n = 101,
 curve.type = "l",
 col, lty, lwd, type,
 ...,
 identifier = "curve")
panel.rug(x = NULL, y = NULL,
 regular = TRUE,
 start = if (regular) 0 else 0.97,
 end = if (regular) 0.03 else 1,
 x.units = rep("npc", 2),
 y.units = rep("npc", 2),
 col, col.line, lty, lwd, alpha,
 ...,
 identifier = "rug")
panel.average(x, y, fun = mean, horizontal = TRUE,
 lwd, lty, col, col.line, type,
 ...,
 identifier = "linejoin")
panel.linejoin(x, y, fun = mean, horizontal = TRUE,
 lwd, lty, col, col.line, type,
 ...,
 identifier = "linejoin")

panel.fill(col, border, ..., identifier = "fill")
panel.grid(h=3, v=3, col, col.line, lty, lwd, x, y, ..., identifier = "grid")
panel.lmline(x, y, ..., identifier = "lmline")
panel.mathdensity(dmath = dnorm, args = list(mean=0, sd=1),
 n = 50, col, col.line, lwd, lty, type,
 ..., identifier = "mathdensity")

```

### Arguments

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code> | Variables defining the contents of the panel. In <code>panel.grid</code> these are optional and are used only to choose an appropriate method of <a href="#">pretty</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>a, b</code> | Coefficients of the line to be added by <code>panel.abline</code> . <code>a</code> can be a vector of length 2, representing the coefficients of the line to be added, in which case <code>b</code> should be missing. <code>a</code> can also be an appropriate 'regression' object, i.e., an object which has a <a href="#">coef</a> method that returns a length 2 numeric vector. The corresponding line will be plotted. The <code>reg</code> argument overrides <code>a</code> if specified.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>coef</code> | Coefficients of the line to be added as a vector of length 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>reg</code>  | A (linear) regression object, with a <a href="#">coef</a> method that gives the coefficients of the corresponding regression line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>h, v</code> | For <code>panel.abline</code> , these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates.<br>For <code>panel.grid</code> , these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative numbers. <code>h=-1</code> and <code>v=-1</code> are intended to make the grids aligned with the axis labels. This doesn't always work; all that actually happens is that the locations are chosen using <a href="#">pretty</a> , which is also how the label positions are chosen in the most common cases (but not for factor variables, for instance). <code>h</code> and <code>v</code> can be negative numbers other than -1, in which case <code>-h</code> and <code>-v</code> (as appropriate) is supplied as the <code>n</code> argument to <a href="#">pretty</a> . |

|                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                     | If <code>x</code> and/or <code>y</code> are specified in <code>panel.grid</code> , they will be used to select an appropriate method for <a href="#">pretty</a> . This is particularly useful while plotting date-time objects.                                                                                                                                                                                          |
| <code>reference</code>                              | A logical flag determining whether the default graphical parameters for <code>panel.abline</code> should be taken from the “reference.line” parameter settings. The default is to take them from the “add.line” settings. The <code>panel.refline</code> function is a wrapper around <code>panel.abline</code> that calls it with <code>reference = TRUE</code> .                                                       |
| <code>expr</code>                                   | An expression considered as a function of <code>x</code> , or a function, to be plotted as a curve.                                                                                                                                                                                                                                                                                                                      |
| <code>n</code>                                      | The number of points to use for drawing the curve.                                                                                                                                                                                                                                                                                                                                                                       |
| <code>from, to</code>                               | optional lower and upper <code>x</code> -limits of curve. If missing, limits of current panel are used                                                                                                                                                                                                                                                                                                                   |
| <code>curve.type</code>                             | Type of curve (“p” for points, etc), passed to <a href="#">llines</a>                                                                                                                                                                                                                                                                                                                                                    |
| <code>regular</code>                                | A logical flag indicating whether the ‘rug’ is to be drawn on the ‘regular’ side (left / bottom) or not (right / top).                                                                                                                                                                                                                                                                                                   |
| <code>start, end</code>                             | endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of <code>regular</code> , and cover 3% of the panel width and height.                                                                                                                                                                                                                                            |
| <code>x.units, y.units</code>                       | Character vectors, replicated to be of length two. Specifies the (grid) units associated with <code>start</code> and <code>end</code> above. <code>x.units</code> and <code>y.units</code> are for the rug on the <code>x</code> -axis and <code>y</code> -axis respectively (and thus are associated with <code>start</code> and <code>end</code> values on the <code>y</code> and <code>x</code> scales respectively). |
| <code>col, col.line, lty, lwd, alpha, border</code> | Graphical parameters.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>type</code>                                   | Usually ignored by the panel functions documented here; the argument is present only to make sure an explicitly specified type argument (perhaps meant for another function) does not affect the display.                                                                                                                                                                                                                |
| <code>fun</code>                                    | The function that will be applied to the subset of <code>x</code> values (or <code>y</code> if <code>horizontal</code> is <code>FALSE</code> ) determined by the unique values of <code>y</code> ( <code>x</code> ).                                                                                                                                                                                                     |
| <code>horizontal</code>                             | A logical flag. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the roles of <code>x</code> and <code>y</code> are switched; <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation.                                                                                                          |
| <code>dmath</code>                                  | A vectorized function that produces density values given a numeric vector named <code>x</code> , e.g., <a href="#">dnorm</a> .                                                                                                                                                                                                                                                                                           |
| <code>args</code>                                   | A list giving additional arguments to be passed to <code>dmath</code> .                                                                                                                                                                                                                                                                                                                                                  |
| <code>...</code>                                    | Further arguments, typically graphical parameters, passed on to other low-level functions as appropriate. Color can usually be specified by <code>col</code> , <code>col.line</code> , and <code>col.symbol</code> , the last two overriding the first for lines and points respectively.                                                                                                                                |
| <code>identifier</code>                             | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                      |

## Details

`panel.abline` adds a line of the form  $y = a + b * x$ , or vertical and/or horizontal lines. Graphical parameters are obtained from the “add.line” settings by default. `panel.refline` is similar, but uses the “reference.line” settings for the defaults.

`panel.grid` draws a reference grid.

`panel.curve` adds a curve, similar to what [curve](#) does with `add = TRUE`. Graphical parameters for the curve are obtained from the “`add.line`” setting.

`panel.average` treats one of `x` and `y` as a factor (according to the value of `horizontal`), calculates `fun` applied to the subsets of the other variable determined by each unique value of the factor, and joins them by a line. Can be used in conjunction with `panel.xyplot`, and more commonly with [panel.superpose](#) to produce interaction plots.

`panel.linejoin` is an alias for `panel.average`. It is retained for back-compatibility, and may go away in future.

`panel.mathdensity` plots a (usually theoretical) probability density function. This can be useful in conjunction with `histogram` and `densityplot` to visually assess goodness of fit (note, however, that `qqmath` is more suitable for this).

`panel.rug` adds a *rug* representation of the (marginal) data to the panel, much like [rug](#).

`panel.lmline(x, y)` is equivalent to `panel.abline(lm(y ~ x))`.

### Examples

```
Interaction Plot

bwplot(yield ~ site, barley, groups = year,
 panel = function(x, y, groups, subscripts, ...) {
 panel.grid(h = -1, v = 0)
 panel.stripplot(x, y, ..., jitter.data = TRUE, grid = FALSE,
 groups = groups, subscripts = subscripts)
 panel.superpose(x, y, ..., panel.groups = panel.average, grid = FALSE,
 groups = groups, subscripts = subscripts)
 },
 auto.key = list(points = FALSE, lines = TRUE, columns = 2))

Superposing a fitted normal density on a Histogram

histogram(~ height | voice.part, data = singer, layout = c(2, 4),
 type = "density", border = "transparent", col.line = "grey60",
 xlab = "Height (inches)",
 ylab = "Density Histogram\n with Normal Fit",
 panel = function(x, ...) {
 panel.histogram(x, ...)
 panel.mathdensity(dmath = dnorm,
 args = list(mean = mean(x), sd = sd(x)), ...)
 })
```

**Description**

A predefined panel function that can be used to add a LOESS smooth based on the provided data.

**Usage**

```
panel.loess(x, y, span = 2/3, degree = 1,
 family = c("symmetric", "gaussian"),
 evaluation = 50,
 lwd, lty, col, col.line, type,
 horizontal = FALSE,
 ..., identifier = "loess")
```

**Arguments**

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                             | Variables defining the data to be used.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>lwd, lty, col, col.line</code>          | Graphical parameters for the added line. <code>col.line</code> overrides <code>col</code> .                                                                                                                                                                                                                                                                                                                                              |
| <code>type</code>                             | Ignored. The argument is present only to make sure that an explicitly specified type argument (perhaps meant for another function) does not affect the display.                                                                                                                                                                                                                                                                          |
| <code>span, degree, family, evaluation</code> | Arguments to <a href="#">loess.smooth</a> , for which <code>panel.loess</code> is essentially a wrapper.                                                                                                                                                                                                                                                                                                                                 |
| <code>horizontal</code>                       | A logical flag controlling which variable is to be treated as the predictor (by default <code>x</code> ) and which as the response (by default <code>y</code> ). If <code>TRUE</code> , the plot is ‘transposed’ in the sense that <code>y</code> becomes the predictor and <code>x</code> the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in <a href="#">bwplot</a> ). |
| <code>...</code>                              | Extra arguments, passed on to <a href="#">panel.lines</a> .                                                                                                                                                                                                                                                                                                                                                                              |
| <code>identifier</code>                       | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                      |

**Value**

The object returned by [loess.smooth](#).

---

**F.2 `panel.qqmathline`**    *Useful panel function with `qqmath`*

---

**Description**

Useful panel function with `qqmath`. Draws a line passing through the points (usually) determined by the .25 and .75 quantiles of the sample and the theoretical distribution.

**Usage**

```
panel.qqmathline(x, y = x,
 distribution = qnorm,
 probs = c(0.25, 0.75),
 qtype = 7,
 groups = NULL,
 ...,
 identifier = "qqmathline")
```

**Arguments**

|                           |                                                                                                                                                 |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | The original sample, possibly reduced to a fewer number of quantiles, as determined by the <code>f.value</code> argument to <code>qqmath</code> |
| <code>y</code>            | an alias for <code>x</code> for backwards compatibility                                                                                         |
| <code>distribution</code> | quantile function for reference theoretical distribution.                                                                                       |
| <code>probs</code>        | numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.                                   |
| <code>qtype</code>        | the type of quantile computation used in <a href="#">quantile</a>                                                                               |
| <code>groups</code>       | optional grouping variable. If non-null, a line will be drawn for each group.                                                                   |
| <code>...</code>          | other arguments.                                                                                                                                |
| <code>identifier</code>   | A character string that is prepended to the names of grobs that are created by this panel function.                                             |

F.2 *panel.smoothScatter**Lattice panel function analogous to smoothScatter***Description**

This function allows the user to place `smoothScatter` plots in lattice graphics.

**Usage**

```
panel.smoothScatter(x, y = NULL,
 nbin = 64, cuts = 255,
 bandwidth,
 col.regions,
 colramp,
 nrpoints = 100,
 transformation = function(x) x^0.25,
 pch = ".",
 cex = 1, col="black",
 range.x,
 ...,
 raster = FALSE,
 subscripts,
 identifier = "smoothScatter")
```

**Arguments**

|                             |                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>              | Numeric vector containing x-values or n by 2 matrix containing x and y values.                                                                                                                                                                                                                                                               |
| <code>y</code>              | Numeric vector containing y-values (optional). The length of x must be the same as that of y.                                                                                                                                                                                                                                                |
| <code>nbin</code>           | Numeric vector of length 1 (for both directions) or 2 (for x and y separately) containing the number of equally spaced grid points for the density estimation.                                                                                                                                                                               |
| <code>cuts</code>           | number of cuts defining the color gradient                                                                                                                                                                                                                                                                                                   |
| <code>bandwidth</code>      | Numeric vector: the smoothing bandwidth. If missing, these functions come up with a more or less useful guess. This parameter then gets passed on to the function <a href="#">bkde2D</a> .                                                                                                                                                   |
| <code>col.regions</code>    | character vector of colors, or a function producing such a vector. Defaults to the <code>col</code> component of the <code>regions</code> setting of the current theme.                                                                                                                                                                      |
| <code>colramp</code>        | Function accepting an integer n as an argument and returning n colors. If missing, the default is derived from <code>col.regions</code> with the following modification: if <code>col.regions</code> is a vector of colors, it is prepended by "white" before being converted into a function using <a href="#">colorRampPalette</a> .       |
| <code>nrpoints</code>       | Numeric vector of length 1 giving number of points to be superimposed on the density image. The first <code>nrpoints</code> points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose <code>nrpoints = Inf</code> . |
| <code>transformation</code> | Function that maps the density scale to the color scale.                                                                                                                                                                                                                                                                                     |
| <code>pch, cex</code>       | graphical parameters for the <code>nrpoints</code> "outlying" points shown in the display                                                                                                                                                                                                                                                    |

|                         |                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------|
| <code>range.x</code>    | see <a href="#">bkde2D</a> for details.                                                                    |
| <code>col</code>        | <a href="#">points</a> color parameter                                                                     |
| <code>...</code>        | Further arguments that are passed on to <a href="#">panel.levelplot</a> .                                  |
| <code>raster</code>     | logical; if TRUE, <a href="#">panel.levelplot.raster</a> is used, making potentially smaller output files. |
| <code>subscripts</code> | ignored, but necessary for handling of ... in certain situations. Likely to be removed in future.          |
| <code>identifier</code> | A character string that is prepended to the names of grobs that are created by this panel function.        |

### Details

This replicates the display part of the `smoothScatter` function by replacing standard graphics calls by grid-compatible ones.

### Value

The function is called for its side effects, namely the production of the appropriate plots on a graphics device.

### Author(s)

Deepayan Sarkar <[deepayan.sarkar@r-project.org](mailto:deepayan.sarkar@r-project.org)>

### Examples

```
ddf <- as.data.frame(matrix(rnorm(40000), ncol = 4) + 1.5 * rnorm(10000))
ddf[, c(2,4)] <- (-ddf[, c(2,4)])
xyplot(V1 ~ V2 + V3, ddf, outer = TRUE,
 panel = panel.smoothScatter, aspect = "iso")
argument to panel.levelplot
xyplot(V1 ~ V2, ddf, panel = panel.smoothScatter, cuts = 10,
 region.type = "contour")
splom(ddf, panel = panel.smoothScatter, nbin = 64, raster = TRUE)
```

### Description

A predefined panel function that can be used to add a spline smooth based on the provided data.

### Usage

```
panel.spline(x, y, npoints = 101,
 lwd = plot.line$lwd,
 lty = plot.line$lty,
 col, col.line = plot.line$col,
 type,
 horizontal = FALSE, ...,
 keep.data = FALSE,
 identifier = "spline")
```

**Arguments**

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                    | Variables defining the data to be used.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>npoints</code>                 | The number of equally spaced points within the range of the predictor at which the fitted model is evaluated for plotting.                                                                                                                                                                                                                                                                                                               |
| <code>lwd, lty, col, col.line</code> | Graphical parameters for the added line. <code>col.line</code> overrides <code>col</code> .                                                                                                                                                                                                                                                                                                                                              |
| <code>type</code>                    | Ignored. The argument is present only to make sure that an explicitly specified type argument (perhaps meant for another function) does not affect the display.                                                                                                                                                                                                                                                                          |
| <code>horizontal</code>              | A logical flag controlling which variable is to be treated as the predictor (by default <code>x</code> ) and which as the response (by default <code>y</code> ). If <code>TRUE</code> , the plot is ‘transposed’ in the sense that <code>y</code> becomes the predictor and <code>x</code> the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in <a href="#">bwplot</a> ). |
| <code>keep.data</code>               | Passed on to <a href="#">smooth.spline</a> . The default here ( <code>FALSE</code> ) is different, and results in the original data not being retained in the fitted spline model. It may be useful to set this to <code>TRUE</code> if the return value of <code>panel.spline</code> , which is the fitted model as returned by <a href="#">smooth.spline</a> , is to be used for subsequent computations.                              |
| <code>...</code>                     | Extra arguments, passed on to <a href="#">smooth.spline</a> and <a href="#">panel.lines</a> as appropriate.                                                                                                                                                                                                                                                                                                                              |
| <code>identifier</code>              | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                      |

**Value**

The fitted model as returned by [smooth.spline](#).

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

[Lattice](#), [smooth.spline](#), [prepanel.spline](#)

**Description**

These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The `x` (and `y` where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

**Usage**

```

panel.superpose(x, y = NULL, subscripts, groups,
 panel.groups = "panel.xyplot",
 ...,
 col, col.line, col.symbol,
 pch, cex, fill, font,
 fontface, fontfamily,
 lty, lwd, alpha,
 type = "p",
 grid = lattice.getOption("default.args")$grid,
 distribute.type = FALSE)
panel.superpose.2(..., distribute.type = TRUE)

panel.superpose.plain(...,
 col, col.line, col.symbol,
 pch, cex, fill, font,
 fontface, fontfamily,
 lty, lwd, alpha)

```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>         | Coordinates of the points to be displayed. Usually numeric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>panel.groups</code> | <p>The panel function to be used for each subgroup of points. Defaults to <code>panel.xyplot</code>.</p> <p>To be able to distinguish between different levels of the originating group inside <code>panel.groups</code>, it will be supplied two special arguments called <code>group.number</code> and <code>group.value</code> which will hold the numeric code and factor level corresponding to the current level of groups. No special care needs to be taken when writing a <code>panel.groups</code> function if this feature is not used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>subscripts</code>   | An integer vector of subscripts giving indices of the x and y values in the original data source. See the corresponding entry in <a href="#">xyplot</a> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>groups</code>       | A grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of groups. The default graphical parameters are obtained from the "superpose.symbol" and "superpose.line" settings using <code>trellis.par.get</code> wherever appropriate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>type</code>         | <p>Usually a character vector specifying how each group should be drawn. Formally, it is passed on to the <code>panel.groups</code> function, which must know what to do with it. By default, <code>panel.groups</code> is <a href="#">panel.xyplot</a>, whose help page describes the admissible values.</p> <p>The functions <code>panel.superpose</code> and <code>panel.superpose.2</code> differ only in the default value of <code>distribute.type</code>, which controls the way the <code>type</code> argument is interpreted. If <code>distribute.type = FALSE</code>, then the interpretation is the same as for <code>panel.xyplot</code> for each of the unique groups. In other words, if <code>type</code> is a vector, all the individual components are honoured concurrently. If <code>distribute.type = TRUE</code>, <code>type</code> is replicated to be as long as the number of unique values in groups, and one component used for the points corresponding to the each different group. Even in this case, it is possible to request multiple types per group, specifying <code>type</code> as a list, each component being the desired type vector for the corresponding group.</p> |

|                                         |                                                                                                                                                                                                                           |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                         | If <code>distribute.type = FALSE</code> , any occurrence of "g" in <code>type</code> causes a grid to be drawn, and all such occurrences are removed before <code>type</code> is passed on to <code>panel.groups</code> . |
| <code>grid</code>                       | Logical flag specifying whether a background reference grid should be drawn. See <a href="#">panel.xyplot</a> for details.                                                                                                |
| <code>col</code>                        | A vector color specification. See Details.                                                                                                                                                                                |
| <code>col.line</code>                   | A vector color specification. See Details.                                                                                                                                                                                |
| <code>col.symbol</code>                 | A vector color specification. See Details.                                                                                                                                                                                |
| <code>pch</code>                        | A vector plotting character specification. See Details.                                                                                                                                                                   |
| <code>cex</code>                        | A vector size factor specification. See Details.                                                                                                                                                                          |
| <code>fill</code>                       | A vector fill color specification. See Details.                                                                                                                                                                           |
| <code>font, fontface, fontfamily</code> | A vector color specification. See Details.                                                                                                                                                                                |
| <code>lty</code>                        | A vector color specification. See Details.                                                                                                                                                                                |
| <code>lwd</code>                        | A vector color specification. See Details.                                                                                                                                                                                |
| <code>alpha</code>                      | A vector alpha-transparency specification. See Details.                                                                                                                                                                   |
| <code>...</code>                        | Extra arguments. Passed down to <code>panel.superpose</code> from <code>panel.superpose.2</code> , and to <code>panel.groups</code> from <code>panel.superpose</code> .                                                   |
| <code>distribute.type</code>            | logical controlling interpretation of the <code>type</code> argument.                                                                                                                                                     |

### Details

`panel.superpose` divides up the `x` (and optionally `y`) variable(s) by the unique values of `groups[subscripts]`, and plots each subset with different graphical parameters. The graphical parameters (`col.symbol`, `pch`, etc.) are usually supplied as suitable atomic vectors, but can also be lists. When `panel.groups` is called for the *i*-th level of groups, the corresponding element of each graphical parameter is passed to it. In the list form, the individual components can themselves be vectors.

The actual plot for each subgroup is created by the `panel.groups` function. With the default `panel.groups`, the `col` argument is overridden by `col.line` and `col.symbol` for lines and points respectively, which default to the "superpose.line" and "superpose.symbol" settings. However, `col` will still be supplied as an argument to `panel.groups` functions that make use of it, with a default of "black". The defaults of other graphical parameters are also taken from the "superpose.line" and "superpose.symbol" settings as appropriate. The `alpha` parameter takes its default from the "superpose.line" setting.

`panel.superpose` and `panel.superpose.2` differ essentially in how `type` is interpreted by default. The default behaviour in `panel.superpose` is the opposite of that in `S`, which is the same as that of `panel.superpose.2`.

`panel.superpose.plain` is the same as `panel.superpose`, except that the default settings for the style arguments are the same for all groups and are taken from the default plot style. It is used in [xyplot.ts](#).

**See Also**

Different functions when used as `panel.groups` gives different types of plots, for example [panel.xyplot](#), [panel.dotplot](#) and [panel.average](#) (This can be used to produce interaction plots).

See [Lattice](#) for an overview of the package, and [xyplot](#) for common arguments (in particular, the discussion of the extended formula interface and the `groups` argument).

F.2 *panel.violin**Panel Function to create Violin Plots***Description**

This is a panel function that can create a violin plot. It is typically used in a high-level call to `bwplot`.

**Usage**

```
panel.violin(x, y, box.ratio = 1, box.width,
 horizontal = TRUE,
 alpha, border, lty, lwd, col,
 varwidth = FALSE,
 bw, adjust, kernel, window,
 width, n = 50, from, to, cut,
 na.rm, ...,
 identifier = "violin")
```

**Arguments**

|                                                                         |                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                                                       | numeric vector or factor. Violin plots are drawn for each unique value of <code>y</code> ( <code>x</code> ) if <code>horizontal</code> is <code>TRUE</code> ( <code>FALSE</code> )                                                                                                                             |
| <code>box.ratio</code>                                                  | ratio of the thickness of each violin and inter violin space                                                                                                                                                                                                                                                   |
| <code>box.width</code>                                                  | thickness of the violins in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.                                                                |
| <code>horizontal</code>                                                 | logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. See documentation of <a href="#">bwplot</a> for a fuller explanation.                                                        |
| <code>alpha, border, lty, lwd, col</code>                               | graphical parameters controlling the violin. Defaults are taken from the “ <code>plot.polygon</code> ” settings.                                                                                                                                                                                               |
| <code>varwidth</code>                                                   | logical. If <code>FALSE</code> , the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by <code>box.ratio</code> ). If <code>TRUE</code> , densities across violins will have comparable scale. |
| <code>bw, adjust, kernel, window, width, n, from, to, cut, na.rm</code> | arguments to <a href="#">density</a> , passed on as appropriate                                                                                                                                                                                                                                                |
| <code>...</code>                                                        | arguments passed on to <code>density</code> .                                                                                                                                                                                                                                                                  |
| <code>identifier</code>                                                 | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                            |

**Details**

Creates Violin plot of *x* for every level of *y*. Note that most arguments controlling the display can be supplied to the high-level (typically `bwplot`) call directly.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

[bwplot](#), [density](#)

**Examples**

```
bwplot(voice.part ~ height, singer,
 panel = function(..., box.ratio) {
 panel.violin(..., col = "transparent",
 varwidth = FALSE, box.ratio = box.ratio)
 panel.bwplot(..., fill = NULL, box.ratio = .1)
 })
```

---

F.3 *prepanel.default*     *Default Prepanel Functions*

---

**Description**

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.

**Usage**

```
prepanel.default.bwplot(x, y, horizontal, nlevels, origin, stack, ...)
prepanel.default.histogram(x, breaks, equal.widths, type, nint, ...)
prepanel.default.qq(x, y, ...)
prepanel.default.xyplot(x, y, type, subscripts, groups, ...)
prepanel.default.cloud(perspective, distance,
 xlim, ylim, zlim,
 screen = list(z = 40, x = -60),
 R.mat = diag(4),
 aspect = c(1, 1), panel.aspect = 1,
 ..., zoom = 0.8)
prepanel.default.levelplot(x, y, subscripts, ...)
prepanel.default.qqmath(x, f.value, distribution, qtype,
 groups, subscripts, ..., tails.n = 0)
prepanel.default.densityplot(x, darg, groups, weights, subscripts, ...)
prepanel.default.parallel(x, y, z, ..., horizontal.axis)
prepanel.default.splom(z, ...)
```

**Arguments**

|                                                                                                 |                                                                                                                                                          |
|-------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                                                                               | x and y values, numeric or factor                                                                                                                        |
| <code>horizontal</code>                                                                         | logical, applicable when one of the variables is to be treated as categorical (factor or shingle).                                                       |
| <code>horizontal.axis</code>                                                                    | logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).                                               |
| <code>nlevels</code>                                                                            | number of levels of such a categorical variable.                                                                                                         |
| <code>origin, stack</code>                                                                      | for barcharts or the <code>type="h"</code> plot type                                                                                                     |
| <code>breaks, equal.widths, type, nint</code>                                                   | details of histogram calculations. <code>type</code> has a different meaning in <code>prepanel.default.xyplot</code> (see <a href="#">panel.xyplot</a> ) |
| <code>groups, subscripts</code>                                                                 | See <a href="#">xyplot</a> . Whenever appropriate, calculations are done separately for each group and then combined.                                    |
| <code>weights</code>                                                                            | numeric vector of weights for the density calculations. If this is specified, it is subsetting by subscripts to match it to x.                           |
| <code>perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, panel.aspect, zoom</code> | see <a href="#">panel.cloud</a>                                                                                                                          |
| <code>f.value, distribution, tails.n</code>                                                     | see <code>panel.qqmath</code>                                                                                                                            |
| <code>darg</code>                                                                               | list of arguments passed to <a href="#">density</a>                                                                                                      |
| <code>z</code>                                                                                  | see <a href="#">panel.parallel</a> and <a href="#">panel.pairs</a>                                                                                       |
| <code>qtype</code>                                                                              | type of <a href="#">quantile</a>                                                                                                                         |
| <code>...</code>                                                                                | other arguments, usually ignored                                                                                                                         |

**Value**

A list with components `xlim`, `ylim`, `dx` and `dy`, and possibly `xat` and `yat`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described in the help page for [xyplot](#).

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

---

F.3 *prepanel.functions*
*Useful Prepanel Function for Lattice*

---

**Description**

These are predefined prepanel functions available in Lattice.

**Usage**

```
prepanel.lmline(x, y, ...)
prepanel.qqmathline(x, y = x, distribution = qnorm,
 probs = c(0.25, 0.75), qtype = 7,
 groups, subscripts,
 ...)
prepanel.loess(x, y, span, degree, family, evaluation,
 horizontal = FALSE, ...)
prepanel.spline(x, y, npoints = 101,
 horizontal = FALSE, ...,
 keep.data = FALSE)
```

**Arguments**

|                                  |                                                                                                                                                                                                                           |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, y                             | x and y values, numeric or factor                                                                                                                                                                                         |
| distribution                     | quantile function for theoretical distribution. This is automatically passed in when this is used as a prepanel function in qqmath.                                                                                       |
| qtype                            | type of <a href="#">quantile</a>                                                                                                                                                                                          |
| probs                            | numeric vector of length two, representing probabilities. If used with aspect="xy", the aspect ratio will be chosen to make the line passing through the corresponding quantile pairs as close to 45 degrees as possible. |
| span, degree, family, evaluation | Arguments controlling the underlying <a href="#">loess</a> smooth.                                                                                                                                                        |
| horizontal, npoints              | See documentation for corresponding panel function.                                                                                                                                                                       |
| keep.data                        | Ignored. Present to capture argument of the same name in <a href="#">smooth.spline</a> .                                                                                                                                  |
| groups, subscripts               | See <a href="#">xyplot</a> . Whenever appropriate, calculations are done separately for each group and then combined.                                                                                                     |
| ...                              | Other arguments. These are passed on to other functions if appropriate (in particular, <a href="#">smooth.spline</a> ), and ignored otherwise.                                                                            |

**Details**

All these prepanel functions compute the limits to be large enough to contain all points as well as the relevant smooth.

In addition, `prepanel.lmline` computes the dx and dy such that it reflects the slope of the linear regression line; for `prepanel.qqmathline`, this is the slope of the line passing through the quantile pairs specified by `probs`. For `prepanel.loess` and `prepanel.spline`, dx and dy reflect the piecewise slopes of the nonlinear smooth.

**Value**

usually a list with components `xlim`, `ylim`, `dx` and `dy`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described under [xyplot](#). There are also several `prepanel` functions that serve as the default for high level functions, see [prepanel.default.xyplot](#)

---

G axis.default

*Default axis annotation utilities*

---

**Description**

Lattice functions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The `xscale.components` and `yscale.components` arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the `axis` argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additionally be used as components of user written replacements.

**Usage**

```
xscale.components.default(lim,
 packet.number = 0,
 packet.list = NULL,
 top = TRUE,
 ...)
yscale.components.default(lim,
 packet.number = 0,
 packet.list = NULL,
 right = TRUE,
 ...)
axis.default(side = c("top", "bottom", "left", "right"),
 scales, components, as.table,
 labels = c("default", "yes", "no"),
 ticks = c("default", "yes", "no"),
 ..., prefix)
```

**Arguments**

`lim` the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the various date-time representations, they could be vectors of length 2 with the corresponding class.

|                            |                                                                                                                                                                                                                                                                                                |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>packet.number</code> | which packet (counted according to the packet order, described in <a href="#">print.trellis</a> ) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0. |
| <code>packet.list</code>   | list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)                                                     |
| <code>top, right</code>    | the value of the top and right components of the result, as appropriate. See below for interpretation.                                                                                                                                                                                         |
| <code>side</code>          | on which side the axis is to be drawn. The usual partial matching rules apply.                                                                                                                                                                                                                 |
| <code>scales</code>        | the appropriate component of the <code>scales</code> argument supplied to the high level function, suitably standardized.                                                                                                                                                                      |
| <code>components</code>    | list, similar to those produced by <code>xscale.components.default</code> and <code>yscale.components.default</code> .                                                                                                                                                                         |
| <code>as.table</code>      | the <code>as.table</code> argument in the high level function.                                                                                                                                                                                                                                 |
| <code>labels</code>        | whether labels are to be drawn. By default, the rules determined by <code>scales</code> are used.                                                                                                                                                                                              |
| <code>ticks</code>         | whether labels are to be drawn. By default, the rules determined by <code>scales</code> are used.                                                                                                                                                                                              |
| <code>...</code>           | many other arguments may be supplied, and are passed on to other internal functions.                                                                                                                                                                                                           |
| <code>prefix</code>        | A character string identifying the plot being drawn (see <a href="#">print.trellis</a> ). Used to retrieve location of current panel in the overall layout, so that axes can be drawn appropriately.                                                                                           |

## Details

These functions are part of a new API introduced in `lattice 0.14` to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather than test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

## Value

`xscale.components.default` and `yscale.components.default` return a list of the form suitable as the `components` argument of `axis.default`. Valid components in the return value of `xscale.components.default` are:

`num.limit` A numeric limit for the box.

`bottom` A list with two elements, `ticks` and `labels`. `ticks` must be a list with components `at` and `tck` which give the location and lengths of tick marks. `tck` can be a vector, and will be recycled to be as long as `at`. `labels` must be a list with components `at`, `labels`, and `check.overlap`. `at` and `labels` give the location and labels of the tick labels; this is usually the same as the location of the ticks, but is not required to be so. `check.overlap` is a logical flag indicating whether overlapping of labels should be avoided by omitting some of the labels while rendering.

`top` This can be a logical flag; if `TRUE`, `top` is treated as being the same as `bottom`; if `FALSE`, axis annotation for the top axis is omitted. Alternatively, `top` can be a list like `bottom`.

Valid components in the return value of `yscale.components.default` are `left` and `right`. Their interpretations are analogous to (respectively) the `bottom` and `top` components described above.

 main = "Yearly temperature in New Haven, CT")

```

---

G banking

*Banking*

---

## Description

Calculates banking slope

## Usage

```
banking(dx, dy)
```

## Arguments

dx, dy                      vector of consecutive x, y differences.

## Details

banking is the banking function used when aspect = "xy" in high level Trellis functions. It is usually not very meaningful except with xyplot. It considers the absolute slopes (based on dx and dy) and returns a value which when adjusted by the panel scale limits will make the median of the above absolute slopes correspond to a 45 degree line.

**Arguments**

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| model           | the model/formula to be parsed. This can be in either of two possible forms, one for 2d and one for 3d formulas, determined by the dimension argument. The 2d formulas are of the form $y \sim x \mid g_1 * \dots * g_n$ , and the 3d formulas are of the form $z \sim x * y \mid g_1 * \dots * g_n$ . In the first form, y may be omitted. The conditioning variables $g_1, \dots, g_n$ can be omitted in either case. |
| data            | the environment/dataset where the variables in the formula are evaluated.                                                                                                                                                                                                                                                                                                                                               |
| dimension       | dimension of the model, see above                                                                                                                                                                                                                                                                                                                                                                                       |
| subset          | index for choosing a subset of the data frame                                                                                                                                                                                                                                                                                                                                                                           |
| groups          | the grouping variable, if present                                                                                                                                                                                                                                                                                                                                                                                       |
| multiple, outer | logicals, determining how a '+' in the y and x components of the formula are processed. See <a href="#">xyplot</a> for details                                                                                                                                                                                                                                                                                          |
| subscripts      | logical, whether subscripts are to be calculated                                                                                                                                                                                                                                                                                                                                                                        |
| drop            | logical or list, similar to the drop.unused.levels argument in <a href="#">xyplot</a> , indicating whether unused levels of conditioning factors and data variables that are factors are to be dropped.                                                                                                                                                                                                                 |

**Value**

returns a list with several components, including left, right, left.name, right.name, condition for 2-D, and left, right.x, right.y, left.name, right.x.name, right.y.name, condition for 3-D. Other possible components are groups, subscr

G packet.panel.default

*Associating Packets with Panels*

---

**Description**

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

**Usage**

```
packet.panel.default(layout, condlevels, page, row, column,
 skip, all.pages.skip = TRUE)
```

**Arguments**

|                   |                                                                                                                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| layout            | the layout argument in high level functions, suitably standardized.                                                                                                                        |
| condlevels        | a list of levels of conditioning variables, after relevant permutations and/or re-ordering of levels                                                                                       |
| page, row, column | the location of the panel in the coordinate system of pages, rows and columns.                                                                                                             |
| skip              | the skip argument in high level functions                                                                                                                                                  |
| all.pages.skip    | whether skip should be replicated over all pages. If FALSE, skip will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages. |

**Value**

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is `p`, then the `i`-th conditioning variable will have level `condlevels[[i]][p[i]]`.

**Examples**

```
packet.panel.page <- function(n)
{
 ## returns a function that when used as the 'packet.panel'
 ## argument in print.trellis plots page number 'n' only
 function(layout, page, ...) {
 stopifnot(layout[3] == 1)
 packet.panel.default(layout = layout, page = n, ...)
 }
}

data(mtcars)
HP <- equal.count(mtcars$hp, 6)
p <-
 xyplot(mpg ~ disp | HP * factor(cyl),
 mtcars, layout = c(0, 6, 1))

print(p, packet.panel = packet.panel.page(1))
print(p, packet.panel = packet.panel.page(2))
```

G *panel.axis**Panel Function for Drawing Axis Ticks and Labels***Description**

`panel.axis` is the function used by `lattice` to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. `current.panel.limits` can be used to retrieve a panel's x and y limits.

**Usage**

```
panel.axis(side = c("bottom", "left", "top", "right"),
 at,
 labels = TRUE,
 draw.labels = TRUE,
 check.overlap = FALSE,
 outside = FALSE,
 ticks = TRUE,
 half = !outside,
 which.half,
 tck = as.numeric(ticks),
 rot = if (is.logical(labels)) 0 else c(90, 0),
 text.col, text.alpha, text.cex, text.font,
 text.fontfamily, text.fontface, text.lineheight,
 line.col, line.lty, line.lwd, line.alpha)

current.panel.limits(unit = "native")
```

**Arguments**

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>side</code>          | A character string indicating which side axes are to be drawn on. Partial specification is allowed.                                                                                                                                                                                                                                                                                                                     |
| <code>at</code>            | Numeric vector giving location of labels. Can be missing, in which case they are computed from the native coordinates of the active viewport.                                                                                                                                                                                                                                                                           |
| <code>labels</code>        | The labels to go along with <code>at</code> , as a character vector or a vector of expressions. This only makes sense provided <code>at</code> is explicitly specified, as otherwise the provided labels may not match the computed <code>at</code> values. Alternatively, <code>labels</code> can be a logical flag: If <code>TRUE</code> , the labels are derived from <code>at</code> , otherwise, labels are empty. |
| <code>draw.labels</code>   | A logical indicating whether labels are to be drawn.                                                                                                                                                                                                                                                                                                                                                                    |
| <code>check.overlap</code> | A logical, whether to check for overlapping of labels. This also has the effect of removing <code>at</code> values that are 'too close' to the limits.                                                                                                                                                                                                                                                                  |
| <code>outside</code>       | A logical flag, indicating whether to draw the labels outside the panel or inside. Note that <code>outside=TRUE</code> will only have a visible effect if clipping is disabled for the viewport (panel).                                                                                                                                                                                                                |
| <code>ticks</code>         | Logical flag, whether to draw the tickmarks.                                                                                                                                                                                                                                                                                                                                                                            |
| <code>half</code>          | Logical flag, indicating whether only around half the scales will be drawn for each side. This is primarily used for axis labeling in <a href="#">splom</a> .                                                                                                                                                                                                                                                           |

|                                                                                    |                                                                                                                                                                                                 |
|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>which.half</code>                                                            | Character string, either "lower" or "upper", indicating which half is to be used for tick locations if <code>half = TRUE</code> . Defaults to whichever is suitable for <a href="#">splom</a> . |
| <code>tck</code>                                                                   | A numeric scalar multiplier for tick length. Can be negative, in which case the ticks point inwards.                                                                                            |
| <code>rot</code>                                                                   | Rotation angle(s) for labels in degrees. Can be a vector of length 2 for x- and y-axes.                                                                                                         |
| <code>text.col</code>                                                              | Color for the axis label text. See <a href="#">gpar</a> for more details on this and the other graphical parameters listed below.                                                               |
| <code>text.alpha</code>                                                            | Alpha-transparency value for the axis label text.                                                                                                                                               |
| <code>text.cex</code>                                                              | Size multiplier for the axis label text.                                                                                                                                                        |
| <code>text.font</code> , <code>text.fontfamily</code> , <code>text.fontface</code> | Font for the axis label text.                                                                                                                                                                   |
| <code>text.lineheight</code>                                                       | Line height for the axis label text.                                                                                                                                                            |
| <code>line.col</code>                                                              | Color for the axis label text.                                                                                                                                                                  |
| <code>line.lty</code>                                                              | Color for the axis.                                                                                                                                                                             |
