| <code>line.lwd</code>                                                              | Color for the axis.                                                                                                                                                                             |
| <code>line.alpha</code>                                                            | Alpha-transparency value for the axis.                                                                                                                                                          |
| <code>unit</code>                                                                  | Which grid <a href="#">unit</a> the values should be in.                                                                                                                                        |

### Details

`panel.axis` can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in [panel.pairs](#) for [splom](#), as well as for all the usual axis drawing by the print method for "trellis" objects. It can also be used to enhance plots 'after the fact' by adding axes.

### Value

`current.panel.limits` returns a list with components `xlim` and `ylim`, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by [unit](#), by default "native".

---

G *panel.number*
*Accessing Auxiliary Information During Plotting*

---

## Description

Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the `panel`, `strip` and `axis` functions. Note that this information is not available to the `prepanel` function, which is executed prior to the actual plotting.

## Usage

```
current.row(prefix)
current.column(prefix)
panel.number(prefix)
packet.number(prefix)
which.packet(prefix)

trellis.currentLayout(which = c("packet", "panel"), prefix)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>which</code>  | whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).                                                                                                              |
| <code>prefix</code> | A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See <a href="#">trellis.focus</a> . |

## Value

`trellis.currentLayout` returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel; see below) occupies that position, with 0 indicating the absence of a panel. `current.row` and `current.column` return integer indices specifying which row and column in the layout are currently active. `panel.number` returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). `packet.number` gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. `which.packet` returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.

## Note

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called `panel.number` and `packet.number` that were made available to `panel` and `strip`. If you have written such functions, it should be enough to replace instances of `panel.number` and `packet.number` by the corresponding function calls. You should

also remove `panel.number` and `packet.number` from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

G Rows

*Extract rows from a list*

---

**Description**

Convenience function to extract subset of a list. Usually used in creating keys.

**Usage**

```
Rows(x, which)
```

**Arguments**

|                    |                                                   |
|--------------------|---------------------------------------------------|
| <code>x</code>     | list with each member a vector of the same length |
| <code>which</code> | index for members of <code>x</code>               |

**Value**

A list similar to `x`, with each `x[[i]]` replaced by `x[[i]][which]`

G utilities.3d*Utility functions for 3-D plots*

---

## Description

These are (related to) the default panel functions for `cloud` and `wireframe`.

## Usage

```
ltransform3dMatrix(screen, R.mat)
ltransform3dto3d(x, R.mat, dist)
```

## Arguments

|                     |                                                                                      |
|---------------------|--------------------------------------------------------------------------------------|
| <code>x</code>      | <code>x</code> can be a numeric matrix with 3 rows for <code>ltransform3dto3d</code> |
| <code>screen</code> | list, as described in <a href="#">panel.cloud</a>                                    |
| <code>R.mat</code>  | 4x4 transformation matrix in homogeneous coordinates                                 |
| <code>dist</code>   | controls transformation to account for perspective viewing                           |

## Details

`ltransform3dMatrix` and `ltransform3dto3d` are utility functions to help in computation of projections. These functions are used inside the panel functions for `cloud` and `wireframe`. They may be useful in user-defined panel functions as well.

The first function takes a list of the form of the `screen` argument in `cloud` and `wireframe` and a `R.mat`, a 4x4 transformation matrix in homogeneous coordinates, to return a new 4x4 transformation matrix that is the result of applying `R.mat` followed by the rotations in `screen`. The second function applies a 4x4 transformation matrix in homogeneous coordinates to a 3xn matrix representing points in 3-D space, and optionally does some perspective computations. (There has been no testing with non-trivial transformation matrices, and my knowledge of the homogeneous coordinate system is very limited, so there may be bugs here.)

H barley

*Yield data from a Minnesota barley trial***Description**

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

**Usage**

barley

**Format**

A data frame with 120 observations on the following 4 variables.

**yield** Yield (averaged across three blocks) in bushels/acre.

**variety** Factor with levels "Svansota", "No. 462", "Manchuria", "No. 475", "Velvet", "Peatland", "Glabron", "No. 457", "Wisconsin No. 38", "Tebi".

**year** Factor with levels 1932, 1931

**site** Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm", "Morris", "Crookston", "Waseca"

**Details**

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crookston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year\*Site\*Variety\*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

**Author(s)**

Documentation contributed by Kevin Wright.

H environmental

*Atmospheric environmental conditions in New York City*

---

**Description**

Daily measurements of ozone concentration, wind speed, temperature and solar radiation in New York City from May to September of 1973.

**Usage**

```
environmental
```

**Format**

A data frame with 111 observations on the following 4 variables.

**ozone** Average ozone concentration (of hourly measurements) of in parts per billion.

**radiation** Solar radiation (from 08:00 to 12:00) in langleys.

**temperature** Maximum daily emperature in degrees Fahrenheit.

**wind** Average wind speed (at 07:00 and 10:00) in miles per hour.

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

Bruntz, S. M., W. S. Cleveland, B. Kleiner, and J. L. Warner. (1974). The Dependence of Ambient Ozone on Solar Radiation, Wind, Temperature, and Mixing Height. In *Symposium on Atmospheric Diffusion and Air Pollution*, pages 125–128. American Meterological Society, Boston.

**References**

**Examples**

```
Scatter plot matrix with loess lines
splom(~environmental,
 panel=function(x,y){
 panel.xyplot(x,y)
 panel.loess(x,y)
 }
)

Conditioned plot similar to figure 5.3 from Cleveland
attach(environmental)
Temperature <- equal.count(temperature, 4, 1/2)
Wind <- equal.count(wind, 4, 1/2)
xyplot((ozone^(1/3)) ~ radiation | Temperature * Wind,
 aspect=1,
 prepanel = function(x, y)
 prepanel.loess(x, y, span = 1),
 panel = function(x, y){
 panel.grid(h = 2, v = 2)
 panel.xyplot(x, y, cex = .5)
 panel.loess(x, y, span = 1)
 },
 xlab = "Solar radiation (langleys)",
 ylab = "Ozone (cube root ppb)")
detach()

Similar display using the coplot function
with(environmental,{
 coplot((ozone^.33) ~ radiation | temperature * wind,
 number=c(4,4),
 panel = function(x, y, ...) panel.smooth(x, y, span = .8, ...),
 xlab="Solar radiation (langleys)",
 ylab="Ozone (cube root ppb)")
})
```

H ethanol

*Engine exhaust fumes from burning ethanol***Description**

Ethanol fuel was burned in a single-cylinder engine. For various settings of the engine compression and equivalence ratio, the emissions of nitrogen oxides were recorded.

**Usage**

```
ethanol
```

**Format**

A data frame with 88 observations on the following 3 variables.

**NOx** Concentration of nitrogen oxides (NO and NO<sub>2</sub>) in micrograms/J.

**C** Compression ratio of the engine.

**E** Equivalence ratio—a measure of the richness of the air and ethanol fuel mixture.

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

Brinkman, N.D. (1981) Ethanol Fuel—A Single-Cylinder Engine Study of Efficiency and Exhaust Emissions. *SAE transactions*, **90**, 1410–1424.

**References**

Cleveland, William S. (1993) *Visualizing Data*. Hobart Press, Summit, New Jersey.

**Examples**

```
Constructing panel functions on the fly
EE <- equal.count(ethanol$E, number=9, overlap=1/4)
xyplot(NOx ~ C | EE, data = ethanol,
 prepanel = function(x, y) prepanel.loess(x, y, span = 1),
 xlab = "Compression ratio", ylab = "NOx (micrograms/J)",
 panel = function(x, y) {
 panel.grid(h=-1, v= 2)
 panel.xyplot(x, y, grid = FALSE)
 panel.loess(x, y, span = 1)
 },
 aspect = "xy")

Wireframe loess surface fit. See Figure 4.61 from Cleveland.
require(stats)
with(ethanol, {
 eth.lo <- loess(NOx ~ C * E, span = 1/3, parametric = "C",
 drop.square = "C", family="symmetric")
 eth.marginal <- list(C = seq(min(C), max(C), length.out = 25),
 E = seq(min(E), max(E), length.out = 25))
 eth.grid <- expand.grid(eth.marginal)
 eth.fit <- predict(eth.lo, eth.grid)
 wireframe(eth.fit ~ eth.grid$C * eth.grid$E,
 shade=TRUE,
 screen = list(z = 40, x = -60, y=0),
 distance = .1,
 xlab = "C", ylab = "E", zlab = "NOx")
})
```

---

H melanoma

---

*Melanoma skin cancer incidence*

---

**Description**

These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

**Usage**

```
melanoma
```

**Format**

A data frame with 37 observations on the following 2 variables.

**year** Years 1936 to 1972.

**incidence** Rate of melanoma cancer per 100,000 population.

**Note**

This dataset is not related to the [melanoma](#) dataset in the **boot** package with the same name.

The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per *million*, but this is not consistent with data found at the National Cancer Institute (<https://www.cancer.gov/>).

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

Houghton, A., E. W. Munster, and M. V. Viola. (1978). Increased Incidence of Malignant Melanoma After Peaks of Sunspot Activity. *The Lancet*, **8**, 759–760.

**References**

**Examples**

```
Time-series plot. Figure 3.64 from Cleveland.
xyplot(incidence ~ year,
 data = melanoma,
 aspect = "xy",
 panel = function(x, y)
 panel.xyplot(x, y, type="o", pch = 16),
 ylim = c(0, 6),
 xlab = "Year",
 ylab = "Incidence")
```

---

H singer

*Heights of New York Choral Society singers*

---

**Description**

Heights in inches of the singers in the New York Choral Society in 1979. The data are grouped according to voice part. The vocal range for each voice part increases in pitch according to the following order: Bass 2, Bass 1, Tenor 2, Tenor 1, Alto 2, Alto 1, Soprano 2, Soprano 1.

**Usage**

```
singer
```

**Format**

A data frame with 235 observations on the following 2 variables.

**height** Height in inches of the singers.

**voice.part** (Unordered) factor with levels "Bass 2", "Bass 1", "Tenor 2", "Tenor 1", "Alto 2", "Alto 1", "Soprano 2", "Soprano 1".

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

Chambers, J.M., W. S. Cleveland, B. Kleiner, and P. A. Tukey. (1983). *Graphical Methods for Data Analysis*. Chapman and Hall, New York.

**References**

Cleveland, William S. (1993) *Visualizing Data*. Hobart Press, Summit, New Jersey.

**Examples**

```
Separate histogram for each voice part (Figure 1.2 from Cleveland)
histogram(~ height | voice.part,
 data = singer,
 aspect = 1,
 layout = c(2, 4),
 nint = 15,
 xlab = "Height (inches)")

Quantile-Quantile plot (Figure 2.11 from Cleveland)
qqmath(~ height | voice.part,
 data = singer,
 aspect = 1,
 layout = c(2,4),
 prepanel = prepanel.qqmathline,
 panel = function(x, ...) {
 panel.grid()
 panel.qqmathline(x, ...)
 panel.qqmath(x, ..., grid = FALSE)
 },
 xlab = "Unit Normal Quantile",
 ylab="Height (inches)")
```

**Description**

These datasets record mortality rates across all ages in the USA by cause of death, sex, and rural/urban status, 2011–2013. The two datasets represent the national aggregate rates and the region-wise rates for each administrative region under the Department of Health and Human Services (HHS).

**Usage**

USMortality  
USRegionalMortality

**Format**

USRegionalMortality is a data frame with 400 observations on the following 6 variables.

Region A factor specifying HHS Region. See details.

Status A factor with levels Rural and Urban

Sex A factor with levels Female and Male

Cause Cause of death. A factor with levels Alzheimers, Cancer, Cerebrovascular diseases, Diabetes, Flu and pneumonia, Heart disease, Lower respiratory, Nephritis, Suicide, and Unintentional injuries

Rate Age-adjusted death rate per 100,000 population

SE Standard error for the rate

USMortality is a data frame with 40 observations, containing the same variables with the exception of Region.

**Details**

The region-wise data give estimated rates separately for each of 10 HHS regions. The location of the regional offices and their coverage area, available from <https://www.hhs.gov/about/agencies/iea/regional-offices/index.html>, is given below.

**HHS Region 01 - Boston:** Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont

**HHS Region 02 - New York:** New Jersey, New York, Puerto Rico, and the Virgin Islands

**HHS Region 03 - Philadelphia:** Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, and West Virginia

**HHS Region 04 - Atlanta:** Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee

**HHS Region 05 - Chicago:** Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin

**HHS Region 06 - Dallas:** Arkansas, Louisiana, New Mexico, Oklahoma, and Texas

**HHS Region 07 - Kansas City:** Iowa, Kansas, Missouri, and Nebraska

**HHS Region 08 - Denver:** Colorado, Montana, North Dakota, South Dakota, Utah, and Wyoming

**HHS Region 09 - San Francisco:** Arizona, California, Hawaii, Nevada, American Samoa, Commonwealth of the Northern Mariana Islands, Federated States of Micronesia, Guam, Marshall Islands, and Republic of Palau

**HHS Region 10 - Seattle:** Alaska, Idaho, Oregon, and Washington

**References**

Rural Health Reform Policy Research Center. \_Exploring Rural and Urban Mortality Differences\_, August 2015 Bethesda, MD. <https://ruralhealth.und.edu/projects/health-reform-policy-research-center/rural-urban-mortality>

**Examples**

```
dotplot(reorder(Cause, Rate) ~ Rate | Status,
 data = USMortality, groups = Sex, grid = FALSE,
 par.settings = simpleTheme(pch = 16), auto.key = list(columns = 2),
 scales = list(x = list(log = TRUE, equispaced.log = FALSE)))
dotplot(reorder(Cause, Rate):Sex ~ Rate | Status,
 data = USRegionalMortality, groups = Sex, auto.key = FALSE,
 scales = list(x = list(log = TRUE, equispaced.log = FALSE)))
```

I lset

*Interface to modify Trellis Settings - Defunct***Description**

A (hopefully) simpler alternative to `trellis.par.get/set`. This is deprecated, and the same functionality is now available with `trellis.par.set`

**Usage**

```
lset(theme = col.whitebg())
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                            |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| theme | a list describing how to change the settings of the current active device. Valid components are those in the list returned by <code>trellis.par.get()</code> . Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only. |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Chapter 24

# The mgcv package

---

`anova.gam`

*Approximate hypothesis tests related to GAM fits*

---

### Description

Performs hypothesis tests relating to one or more fitted `gam` objects. For a single fitted `gam` object, Wald tests of the significance of each parametric and smooth term are performed, so interpretation is analogous to [drop1](#) rather than `anova.lm` (i.e. it's like type III ANOVA, rather than a sequential type I ANOVA). Otherwise the fitted models are compared using an analysis of deviance table or GLRT test: this latter approach should not be use to test the significance of terms which can be penalized to zero. Models to be compared should be fitted to the same data using the same smoothing parameter selection method.

### Usage

```
S3 method for class 'gam'
anova(object, ..., dispersion = NULL, test = NULL,
 freq = FALSE)
S3 method for class 'anova.gam'
print(x, digits = max(3, getOption("digits") - 3),...)
```

### Arguments

|                          |                                                                                                                                                   |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object, ...</code> | fitted model objects of class <code>gam</code> as produced by <code>gam()</code> .                                                                |
| <code>x</code>           | an <code>anova.gam</code> object produced by a single model call to <code>anova.gam()</code> .                                                    |
| <code>dispersion</code>  | a value for the dispersion parameter: not normally used.                                                                                          |
| <code>test</code>        | what sort of test to perform for a multi-model call. One of "Chisq", "F" or "Cp". Reset to "Chisq" for extended and general families unless NULL. |
| <code>freq</code>        | whether to use frequentist or Bayesian approximations for parametric term p-values. See <a href="#">summary.gam</a> for details.                  |
| <code>digits</code>      | number of digits to use when printing output.                                                                                                     |

## Details

If more than one fitted model is provided than `anova.glm` is used, with the difference in model degrees of freedom being taken as the difference in effective degrees of freedom (when possible this is a smoothing parameter uncertainty corrected version). For extended and general families this is set so that a GLRT test is used. The p-values resulting from the multi-model case are only approximate, and must be used with care. The approximation is most accurate when the comparison relates to unpenalized terms, or smoothers with a null space of dimension greater than zero. (Basically we require that the difference terms could be well approximated by unpenalized terms with degrees of freedom approximately the effective degrees of freedom). In simulations the p-values are usually slightly too low. For terms with a zero-dimensional null space (i.e. those which can be penalized to zero) the approximation is often very poor, and significance can be greatly overstated: i.e. p-values are often substantially too low. This case applies to random effect terms.

Note also that in the multi-model call to `anova.gam`, it is quite possible for a model with more terms to end up with lower effective degrees of freedom, but better fit, than the notionally null model with fewer terms. In such cases it is very rare that it makes sense to perform any sort of test, since there is then no basis on which to accept the notional null model.

If only one model is provided then the significance of each model term is assessed using Wald like tests, conditional on the smoothing parameter estimates: see [summary.gam](#) and Wood (2013a,b) for details. The p-values provided here are better justified than in the multi model case, and have close to the correct distribution under the null, unless smoothing parameters are poorly identified. ML or REML smoothing parameter selection leads to the best results in simulations as they tend to avoid occasional severe undersmoothing. In replication of the full simulation study of Scheipl et al. (2008) the tests give almost indistinguishable power to the method recommended there, but slightly too low p-values under the null in their section 3.1.8 test for a smooth interaction (the Scheipl et al. recommendation is not used directly, because it only applies in the Gaussian case, and requires model refits, but it is available in package `RLRsim`).

In the single model case `print.anova.gam` is used as the printing method.

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (`freq=TRUE`), since the parametric terms themselves are usually unpenalized. Default P-values for parameteric terms that are penalized using the `paraPen` argument will not be good.

## Value

In the multi-model case `anova.gam` produces output identical to [anova.glm](#), which it in fact uses.

In the single model case an object of class `anova.gam` is produced, which is in fact an object returned from [summary.gam](#).

`print.anova.gam` simply produces tabulated output.

## WARNING

If models 'a' and 'b' differ only in terms with no un-penalized components (such as random effects) then p values from `anova(a,b)` are unreliable, and usually much too low.

Default P-values will usually be wrong for parametric terms penalized using 'paraPen': use `freq=TRUE` to obtain better p-values when the penalties are full rank and represent conventional random effects.

For a single model, interpretation is similar to `drop1`, not `anova.lm`.

bam

---

*Generalized additive models for very large datasets*

---

**Description**

Fits a generalized additive model (GAM) to a very large data set, the term ‘GAM’ being taken to include any quadratically penalized GLM (the extended families listed in [family.mgcv](#) can also be used). The degree of smoothness of model terms is estimated as part of fitting. In use the function is much like [gam](#), except that the numerical methods are designed for datasets containing upwards of several tens of thousands of data (see Wood, Goude and Shaw, 2015). The advantage of bam is much lower memory footprint than [gam](#), but it can also be much faster, for large datasets. bam can also compute on a cluster set up by the [parallel](#) package.

An alternative fitting approach (Wood et al. 2017, Li and Wood, 2019) is provided by the `discrete==TRUE` method. In this case a method based on discretization of covariate values and C code level parallelization (controlled by the `nthreads` argument instead of the `cluster` argument) is used. This extends both the data set and model size that are practical. Number of response data can not exceed `.Machine$integer.max`.

## Usage

```
bam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL,
 na.action=na.omit, offset=NULL, method="fREML", control=list(),
 select=FALSE, scale=0, gamma=1, knots=NULL, sp=NULL, min.sp=NULL,
 paraPen=NULL, chunk.size=10000, rho=0, AR.start=NULL, discrete=FALSE,
 cluster=NULL, nthreads=1, gc.level=0, use.chol=FALSE, samfrac=1,
 coef=NULL, drop.unused.levels=TRUE, G=NULL, fit=TRUE, drop.intercept=NULL,
 in.out=NULL, nei=NULL, ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | A GAM formula (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). This is exactly like the formula for a GLM except that smooth terms, <i>s</i> and <i>te</i> can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).                                                                                                                                                                              |
| family    | This is a family object specifying the distribution and link to use in fitting etc. See <a href="#">glm</a> and <a href="#">family</a> for more details. The extended families listed in <a href="#">family.mgcv</a> can also be used.                                                                                                                                                                                                                                                                              |
| data      | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>gam</code> is called.                                                                                                                                                                                                                                                                    |
| weights   | prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to reweight the contributions of each datum without changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. <code>weights &lt;- weights/mean(weights)</code> ).                                                                                                                   |
| subset    | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| na.action | a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.                                                                                                                                                                                                                                                                                                 |
| offset    | Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula (this used to conform to the behaviour of <code>lm</code> and <code>glm</code> ).                                                                                                                                                                                                                                                            |
| method    | The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Default "fREML" uses fast REML computation. When <code>discrete=TRUE</code> then "NCV" is also possible. |
| control   | A list of fit control parameters to replace defaults returned by <a href="#">gam.control</a> . Any control parameters not supplied stay at their default values.                                                                                                                                                                                                                                                                                                                                                    |
| select    | Should selection penalties be added to the smooth effects, so that they can in principle be penalized out of the model? See <code>gamma</code> to increase penalization. Has the side effect that smooths no longer have a fixed effect component (improper prior from a Bayesian perspective) allowing REML comparison of models with the same fixed effect structure.                                                                                                                                             |

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scale      | If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.                                                                                                                                                                                                                                                                                                               |
| gamma      | Increase above 1 to force smoother fits. gamma is used to multiply the effective degrees of freedom in the GCV/UBRE/AIC score (so $\log(n)/2$ is BIC like). $n/\text{gamma}$ can be viewed as an effective sample size, which allows it to play a similar role for RE/ML smoothing parameter estimation.                                                                                                                                                                                                                                                                                                                         |
| knots      | this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the k value supplied (note that the number of knots is not always just k). See <a href="#">tprs</a> for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.                                                                                                                                                                                                          |
| sp         | A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters. Note that <code>discrete=TRUE</code> may result in re-ordering of variables in tensor product smooths for improved efficiency, and <code>sp</code> must be supplied in re-ordered order. |
| min.sp     | Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters <code>full.sp</code> , in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. <code>length(min.sp)</code> should always be the same as the total number of penalties (so it may be longer than <code>sp</code> , if smooths share smoothing parameters).                                                                                                                                                           |
| paraPen    | optional list specifying any penalties to be applied to parametric model terms. <a href="#">gam.models</a> explains more.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| chunk.size | The model matrix is created in chunks of this size, rather than ever being formed whole. Reset to $4 \times p$ if <code>chunk.size</code> < $4 \times p$ where <code>p</code> is the number of coefficients.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| rho        | An AR1 error model can be used for the residuals (based on dataframe order), of Gaussian-identity link models. This is the AR1 correlation parameter. Standardized residuals (approximately uncorrelated under correct model) returned in <code>std.rs</code> if non zero. Also usable with other models when <code>discrete=TRUE</code> , in which case the AR model is applied to the working residuals and corresponds to a GEE approximation.                                                                                                                                                                                |
| AR.start   | logical variable of same length as data, TRUE at first observation of an independent section of AR1 correlation. Very first observation in data frame does not need this. If NULL then there are no breaks in AR1 correlation.                                                                                                                                                                                                                                                                                                                                                                                                   |
| discrete   | with <code>method="FREML"</code> it is possible to discretize covariates for storage and efficiency reasons. If <code>discrete</code> is TRUE, a number or a vector of numbers for each smoother term, then discretization happens. If numbers are supplied they give the number of discretization bins. Parametric terms use the maximum number specified.                                                                                                                                                                                                                                                                      |
| cluster    | <code>bam</code> can compute the computationally dominant QR decomposition in parallel using <a href="#">parLapply</a> from the <code>parallel</code> package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code.                                                                                                                                                                                                                                                                                                                        |

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nthreads</code>           | Number of threads to use for non-cluster computation (e.g. combining results from cluster nodes). If NA set to <code>max(1, length(cluster))</code> . See details.                                                                                                                                                                                                                                                        |
| <code>gc.level</code>           | to keep the memory footprint down, it can help to call the garbage collector often, but this takes a substantial amount of time. Setting this to zero means that garbage collection only happens when R decides it should. Setting to 2 gives frequent garbage collection. 1 is in between. Not as much of a problem as it used to be, but can really matter for very large datasets.                                     |
| <code>use.chol</code>           | By default bam uses a very stable QR update approach to obtaining the QR decomposition of the model matrix. For well conditioned models an alternative accumulates the crossproduct of the model matrix and then finds its Choleski decomposition, at the end. This is somewhat more efficient, computationally.                                                                                                          |
| <code>samfrac</code>            | For very large sample size Generalized additive models the number of iterations needed for the model fit can be reduced by first fitting a model to a random sample of the data, and using the results to supply starting values. This initial fit is run with sloppy convergence tolerances, so is typically very low cost. <code>samfrac</code> is the sampling fraction to use. 0.1 is often reasonable.               |
| <code>coef</code>               | initial values for model coefficients                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>drop.unused.levels</code> | by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.                                                                                                                                                                                                                                 |
| <code>G</code>                  | if not NULL then this should be the object returned by a previous call to bam with <code>fit=FALSE</code> . Causes all other arguments to be ignored except <code>sp</code> , <code>chunk.size</code> , <code>gamma</code> , <code>nthreads</code> , <code>cluster</code> , <code>rho</code> , <code>gc.level</code> , <code>samfrac</code> , <code>use.chol</code> , <code>method</code> and <code>scale</code> (if >0). |
| <code>fit</code>                | if FALSE then the model is set up for fitting but not estimated, and an object is returned, suitable for passing as the <code>G</code> argument to bam.                                                                                                                                                                                                                                                                   |
| <code>drop.intercept</code>     | Set to TRUE to force the model to really not have the a constant in the parametric model part, even with factor variables present.                                                                                                                                                                                                                                                                                        |
| <code>in.out</code>             | If supplied then this is a two item list of initial values. <code>sp</code> is initial smoothing parameter estimates and <code>scale</code> the initial scale parameter estimate (set to 1 if family does not have one).                                                                                                                                                                                                  |
| <code>nei</code>                | list describing neighbourhood structure for NCV model smoothing parameter selection. See <a href="#">NCV</a> for details.                                                                                                                                                                                                                                                                                                 |
| <code>...</code>                | further arguments for passing on e.g. to <code>gam.fit</code> (such as <code>mustart</code> ).                                                                                                                                                                                                                                                                                                                            |

## Details

When `discrete=FALSE`, bam operates by first setting up the basis characteristics for the smooths, using a representative subsample of the data. Then the model matrix is constructed in blocks using [predict.gam](#). For each block the factor R, from the QR decomposition of the whole model matrix is updated, along with Q'y. and the sum of squares of y. At the end of block processing, fitting takes place, without the need to ever form the whole model matrix.

In the generalized case, the same trick is used with the weighted model matrix and weighted pseudodata, at each step of the PIRLS. Smoothness selection is performed on the working model at each stage (performance oriented iteration), to maintain the small memory footprint. This is trivial to justify in the case of GCV or Cp/UBRE/AIC based model selection, and for REML/ML is justified via the asymptotic multivariate normality of Q'z where z is the IRLS pseudodata.

For full method details see Wood, Goude and Shaw (2015).

Note that POI is not as stable as the default nested iteration used with [gam](#), but that for very large, information rich, datasets, this is unlikely to matter much.

Note also that it is possible to spend most of the computational time on basis evaluation, if an expensive basis is used. In practice this means that the default "tp" basis should be avoided: almost any other basis (e.g. "cr" or "ps") can be used in the 1D case, and tensor product smooths (te) are typically much less costly in the multi-dimensional case.

If `cluster` is provided as a cluster set up using [makeCluster](#) (or [makeForkCluster](#)) from the `parallel` package, then the rate limiting QR decomposition of the model matrix is performed in parallel using this cluster. Note that the speed ups are often not that great. On a multi-core machine it is usually best to set the cluster size to the number of physical cores, which is often less than what is reported by [detectCores](#). Using more than the number of physical cores can result in no speed up at all (or even a slow down). Note that a highly parallel BLAS may negate all advantage from using a cluster of cores. Computing in parallel of course requires more memory than computing in series. See examples.

When `discrete=TRUE` the covariate data are first discretized. Discretization takes place on a smooth by smooth basis, or in the case of tensor product smooths (or any smooth that can be represented as such, such as random effects), separately for each marginal smooth. The required spline bases are then evaluated at the discrete values, and stored, along with index vectors indicating which original observation they relate to. Fitting is by a version of performance oriented iteration/PQL using REML smoothing parameter selection on each iterative working model (as for the default method). The iteration is based on the derivatives of the REML score, without computing the score itself, allowing the expensive computations to be reduced to one parallel block Cholesky decomposition per iteration (plus two basic operations of equal cost, but easily parallelized). Unlike standard POI/PQL, only one step of the smoothing parameter update for the working model is taken at each step (rather than iterating to the optimal set of smoothing parameters for each working model). At each step a weighted model matrix crossproduct of the model matrix is required - this is efficiently computed from the pre-computed basis functions evaluated at the discretized covariate values. Efficient computation with tensor product terms means that some terms within a tensor product may be re-ordered for maximum efficiency. See Wood et al (2017) and Li and Wood (2019) for full details.

With `discrete=TRUE` NCV can be used for smoothing parameter estimation. See [NCV](#) for details of how to set up neighbourhoods using the `nei` argument. NCV is applied to the working penalized linear model using in iterative fitting. The computation is more efficient than that used by [gam](#) provided neighbourhoods are small, but is still costly. It is not efficient for k-fold cross validation, for example. The small neighbourhood restriction is because a matrix of side length given by the neighbourhood side needs to be inverted for each neighbourhood. Because computational cost is typically much higher than for REML, for large data/models it is usually worth basing the NCV criterion on a sub-sample of the full data set. Supplying a sample element of the `nei` list is the way to do this. See [NCV](#).

When `discrete=TRUE` parallel computation is controlled using the `nthreads` argument. For this method no cluster computation is used, and the `parallel` package is not required. Note that actual speed up from parallelization depends on the BLAS installed and your hardware. With the (R default) reference BLAS using several threads can make a substantial difference, but with a single threaded tuned BLAS, such as `openblas`, the effect is less marked (since cache use is typically optimized for one thread, and is then sub optimal for several). However the tuned BLAS is usually much faster than using the reference BLAS, however many threads you use. If you have a multi-threaded BLAS installed then you should leave `nthreads` at 1, since calling a multi-threaded BLAS from multiple threads usually slows things down: the only exception to this is that you might choose to form discrete matrix cross products (the main cost in the fitting routine) in a multi-threaded way, but use single threaded code for other computations: this can be achieved by e.g. `nthreads=c(2,1)`, which would use 2 threads for discrete inner products, and 1 for most code calling BLAS. Not that

the basic reason that multi-threaded performance is often disappointing is that most computers are heavily memory bandwidth limited, not flop rate limited. It is hard to get data to one core fast enough, let alone trying to get data simultaneously to several cores.

`discrete=TRUE` will often produce identical results to the methods without discretization, since covariates often only take a modest number of discrete values anyway, so no approximation at all is involved in the discretization process. Even when some approximation is involved, the differences are often very small as the algorithms discretize marginally whenever possible. For example each margin of a tensor product smooth is discretized separately, rather than discretizing onto a grid of covariate values (for an equivalent isotropic smooth we would have to discretize onto a grid). The marginal approach allows quite fine scale discretization and hence very low approximation error. Note that when using the smooth id mechanism to link smoothing parameters, the discrete method cannot force the linked bases to be identical, so some differences to the none discrete methods will be noticeable.

The extended families given in `family.mgcv` can also be used. The extra parameters of these are estimated by maximizing the penalized likelihood, rather than the restricted marginal likelihood as in `gam`. So estimates may differ slightly from those returned by `gam`. Estimation is accomplished by a Newton iteration to find the extra parameters (e.g. the theta parameter of the negative binomial or the degrees of freedom and scale of the scaled t) maximizing the log likelihood given the model coefficients at each iteration of the fitting procedure.

## Value

An object of class "gam" as described in `gamObject`.

## WARNINGS

For method set to "fREML", "REML" or "ML" the returned smoothness criterion value is for the model itself, otherwise for the working model. The former is comparable to `gam` (but typically a little larger, since it was the working model version that was actually optimized), the latter not.

The routine may be slower than optimal if the default "tp" basis is used.

This routine is less stable than 'gam' for the same dataset.

With `discrete=TRUE`, te terms are efficiently computed, but t2 are not.

Anything close to the maximum n of `.Machine$integer.max` will need a very large amount of RAM and probably `gc.level=1`.

**Examples**

```
library(mgcv)
See help("mgcv-parallel") for using bam in parallel

Sample sizes are small for fast run times.

set.seed(3)
dat <- gamSim(1,n=25000,dist="normal",scale=20)
bs <- "cr"; k <- 12
b <- bam(y ~ s(x0,bs=bs)+s(x1,bs=bs)+s(x2,bs=bs,k=k)+
 s(x3,bs=bs),data=dat)
summary(b)
plot(b,pages=1,rug=FALSE) ## plot smooths, but not rug
plot(b,pages=1,rug=FALSE,seWithMean=TRUE) ## `with intercept' CIs

ba <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+
 s(x3,bs=bs,k=k),data=dat,method="GCV.Cp") ## use GCV
summary(ba)

A Poisson example...

k <- 15
dat <- gamSim(1,n=21000,dist="poisson",scale=.1)

system.time(b1 <- bam(y ~ s(x0,bs=bs)+s(x1,bs=bs)+s(x2,bs=bs,k=k),
 data=dat,family=poisson()))
b1

Similar using faster discrete method...

system.time(b2 <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+
 s(x3,bs=bs,k=k),data=dat,family=poisson(),discrete=TRUE))
b2
```

bam.update

*Update a strictly additive bam model for new data.***Description**

Gaussian with identity link models fitted by [bam](#) can be efficiently updated as new data becomes available, by simply updating the QR decomposition on which estimation is based, and re-optimizing the smoothing parameters, starting from the previous estimates. This routine implements this.

**Usage**

```
bam.update(b, data, chunk.size=10000)
```

**Arguments**

|                         |                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>b</code>          | A gam object fitted by <a href="#">bam</a> and representing a strictly additive model (i.e. gaussian errors, identity link).                                                                                                                  |
| <code>data</code>       | Extra data to augment the original data used to obtain <code>b</code> . Must include a <code>weights</code> column if the original fit was weighted and a <code>AR.start</code> column if <code>AR.start</code> was non NULL in original fit. |
| <code>chunk.size</code> | size of subsets of data to process in one go when getting fitted values.                                                                                                                                                                      |

**Details**

`bam.update` updates the QR decomposition of the (weighted) model matrix of the GAM represented by `b` to take account of the new data. The orthogonal factor multiplied by the response vector is also updated. Given these updates the model and smoothing parameters can be re-estimated, as if the whole dataset (original and the new data) had been fitted in one go. The function will use the same AR1 model for the residuals as that employed in the original model fit (see `rho` parameter of [bam](#)).

Note that there may be small numerical differences in fit between fitting the data all at once, and fitting in stages by updating, if the smoothing bases used have any of their details set with reference to the data (e.g. default knot locations).

**Value**

An object of class "gam" as described in [gamObject](#).

**WARNINGS**

AIC computation does not currently take account of AR model, if used.

```

bandchol

*Choleski decomposition of a band diagonal matrix***Description**

Computes Choleski decomposition of a (symmetric positive definite) band-diagonal matrix, A.

**Usage**

```
bandchol(B)
```

**Arguments**

**B** An n by k matrix containing the diagonals of the matrix A to be decomposed. First row is leading diagonal, next is first sub-diagonal, etc. sub-diagonals are zero padded at the end. Alternatively gives A directly, i.e. a square matrix with  $2k-1$  non zero diagonals (those from the lower triangle are not accessed).

**Details**

Calls dpbtrf from LAPACK. The point of this is that it has  $O(k^2n)$  computational cost, rather than the  $O(n^3)$  required by dense matrix methods.

**Value**

Let  $R$  be the factor such that  $t(R) \% \% R = A$ .  $R$  is upper triangular and if the rows of  $B$  contained the diagonals of  $A$  on entry, then what is returned is an  $n$  by  $k$  matrix containing the diagonals of  $R$ , packed as  $B$  was packed on entry. If  $B$  was square on entry, then  $R$  is returned directly. See examples.

**Examples**

```
require(mgcv)
simulate a banded diagonal matrix
n <- 7;set.seed(8)
A <- matrix(0,n,n)
sdiag(A) <- runif(n);sdiag(A,1) <- runif(n-1)
sdiag(A,2) <- runif(n-2)
A <- crossprod(A)

full matrix form...
bandchol(A)
chol(A) ## for comparison

compact storage form...
B <- matrix(0,3,n)
B[1,] <- sdiag(A);B[2,1:(n-1)] <- sdiag(A,1)
B[3,1:(n-2)] <- sdiag(A,2)
bandchol(B)
```

---

bcg

---

*Censored Box-Cox Gaussian family*

---

**Description**

Family for use with [gam](#) or [bam](#), implementing regression for censored data that can be modelled as Gaussian after Box-Cox transformation. If  $y > 0$  is the response and

$$z = \begin{cases} (y^\lambda - 1)/\lambda & \lambda \neq 0 \\ \log(y) & \lambda = 0 \end{cases}$$

with mean  $\mu$  and standard deviation  $w^{-1/2} \exp(\theta)$ , then  $w^{1/2}(z - \mu) \exp(-\theta)$  follows an  $N(0, 1)$  distribution. That is

$$z \sim N(\mu, e^{2\theta} w^{-1}).$$

$\theta$  is a single scalar for all observations, and similarly Box-Cox parameter  $\lambda$  is a single scalar. Observations may be left, interval or right censored or uncensored.

Note that the regression model here specifies the mean of the Box-Cox transformed response, not the mean of the response itself: this is rather different to the usual GLM approach.

**Usage**

```
bcg(theta=NULL, link="identity")
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                             |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| theta | a 2-vector containing the Box-Cox parameter $\lambda$ and the log standard deviation parameter $\theta$ . If supplied and positive then taken as a fixed value of $\lambda$ and $\exp(\theta)$ . If supplied and second element negative taken as initial value and negative of initial value respectively. |
| link  | The link function: "identity", "log" or "sqrt".                                                                                                                                                                                                                                                             |

**Details**

If the family is used with a vector response, then it is assumed that there is no censoring. If there is censoring then the response should be supplied as a two column matrix. The first column is always numeric. Entries in the second column are as follows.

- If an entry is identical to the corresponding first column entry, then it is an uncensored observation.
- If an entry is numeric and different to the first column entry then there is interval censoring. The first column entry is the lower interval limit and the second column entry is the upper interval limit.  $y$  is only known to be between these limits.
- If the second column entry is 0 then the observation is left censored at the value of the entry in the first column. It is only known that  $y$  is less than or equal to the first column value.
- If the second column entry is Inf then the observation is right censored at the value of the entry in the first column. It is only known that  $y$  is greater than or equal to the first column value.

Any mixture of censored and uncensored data is allowed, but be aware that data consisting only of right and/or left censored data contain very little information.

**Value**

An object of class `extended.family`.

```

---

betar

*GAM beta regression family*

---

## Description

Family for use with [gam](#) or [bam](#), implementing regression for beta distributed data on (0,1). A linear predictor controls the mean,  $\mu$  of the beta distribution, while the variance is then  $\mu(1 - \mu)/(1 + \phi)$ , with parameter  $\phi$  being estimated during fitting, alongside the smoothing parameters.

## Usage

```
betar(theta = NULL, link = "logit", eps=.Machine$double.eps*100)
```

## Arguments

|       |                                                                                                                                                                                                                                                              |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| theta | the extra parameter ( $\phi$ above).                                                                                                                                                                                                                         |
| link  | The link function: one of "logit", "probit", "cloglog" and "cauchit".                                                                                                                                                                                        |
| eps   | the response variable will be truncated to the interval [eps, 1-eps] if there are values outside this range. This truncation is not entirely benign, but too small a value of eps will cause stability problems if there are zeroes or ones in the response. |

## Details

These models are useful for proportions data which can not be modelled as binomial. Note the assumption that data are in (0,1), despite the fact that for some parameter values 0 and 1 are perfectly legitimate observations. The restriction is needed to keep the log likelihood bounded for all parameter values. Any data exactly at 0 or 1 are reset to be just above 0 or just below 1 using the `eps` argument (in fact any observation  $< \text{eps}$  is reset to `eps` and any observation  $> 1 - \text{eps}$  is reset to  $1 - \text{eps}$ ). Note the effect of this resetting. If  $\mu\phi > 1$  then impossible 0s are replaced with highly improbable `eps` values. If the inequality is reversed then 0s with infinite probability density are replaced with `eps` values having high finite probability density. The equivalent condition for 1s is  $(1 - \mu)\phi > 1$ . Clearly all types of resetting are somewhat unsatisfactory, and care is needed if data contain 0s or 1s (often it makes sense to manually reset the 0s and 1s in a manner that somehow reflects the sampling setup).

## Value

An object of class `extended.family`.

## WARNINGS

Do read the details section if your data contain 0s and or 1s.

---

blas.thread.test

*BLAS thread safety*

---

## Description

Most BLAS implementations are thread safe, but some versions of OpenBLAS, for example, are not. This routine is a diagnostic helper function, which you will never need if you don't set `nthreads>1`, and even then are unlikely to need.

## Usage

```
blas.thread.test(n=1000,nt=4)
```

**Arguments**

|    |                                                            |
|----|------------------------------------------------------------|
| n  | Number of iterations to run of parallel BLAS calling code. |
| nt | Number of parallel threads to use                          |

**Details**

While single threaded OpenBLAS 0.2.20 was thread safe, versions 0.3.0-0.3.6 are not, and from version 0.3.7 thread safety of the single threaded OpenBLAS requires making it with the option `USE_LOCKING=1`. The reference BLAS is thread safe, as are MKL and ATLAS. This routine repeatedly calls the BLAS from multi-threaded code and is sufficient to detect the problem in single threaded OpenBLAS 0.3.x.

A multi-threaded BLAS is often no faster than a single-threaded BLAS, while judicious use of threading in the code calling the BLAS can still deliver a modest speed improvement. For this reason it is often better to use a single threaded BLAS and the `nthreads` options to [bam](#) or [gam](#). For `bam(...,discrete=TRUE)` using several threads can be a substantial benefit, especially with the reference BLAS.

The MKL BLAS is multithreaded by default. Under linux setting environment variable `MKL_NUM_THREADS=1` before starting R gives single threaded operation.

bug.reports.mgcv

*Reporting mgcv bugs.*

---

**Description**

mgcv works largely because many people have reported bugs over the years. If you find something that looks like a bug, please report it, so that the package can be improved. mgcv does not have a large development budget, so it is a big help if bug reports follow the following guidelines.

The ideal report consists of an email to <simon.wood@r-project.org> with a subject line including mgcv somewhere, containing

1. The results of running [sessionInfo](#) in the R session where the problem occurs. This provides platform details, R and package version numbers, etc.
2. A brief description of the problem.
3. Short cut and paste-able code that produces the problem, including the code for loading/generating the data (using standard R functions like `load`, `read.table` etc).
4. Any required data files. If you send real data it will only be used for the purposes of debugging.

Of course if you have dug deeper and have an idea of what is causing the problem, that is also helpful to know, as is any suggested code fix. (Don't send a fixed package .tar.gz file, however - I can't use this).

Simon N. Wood <simon.wood@r-project.org>

choldrop

*Deletion and rank one Cholesky factor update***Description**

Given a Cholesky factor,  $R$ , of a matrix,  $A$ , `choldrop` finds the Cholesky factor of  $A[-k, -k]$ , where  $k$  is an integer. `cholup` finds the factor of  $A + uu^T$  (update) or  $A - uu^T$  (downdate).

**Usage**

```
choldrop(R,k)
cholup(R,u,up)
```

**Arguments**

|      |                                             |
|------|---------------------------------------------|
| $R$  | Cholesky factor of a matrix, $A$ .          |
| $k$  | row and column of $A$ to drop.              |
| $u$  | vector defining rank one update.            |
| $up$ | if TRUE compute update, otherwise downdate. |

**Details**

First consider `choldrop`. If  $R$  is upper triangular then  $t(R[, -k]) \%*\% R[, -k] == A[-k, -k]$ , but  $R[, -k]$  has elements on the first sub-diagonal, from its  $k$ th column onwards. To get from this to a triangular Cholesky factor of  $A[-k, -k]$  we can apply a sequence of Givens rotations from the left to eliminate the sub-diagonal elements. The routine does this. If  $R$  is a lower triangular factor then Givens rotations from the right are needed to remove the extra elements. If  $n$  is the dimension of  $R$  then the update has  $O(n^2)$  computational cost.

`cholup` (which assumes  $R$  is upper triangular) updates based on the observation that  $R^T R + uu^T = [u, R^T][u, R^T]^T = [u, R^T]Q^T Q[u, R^T]^T$ , and therefore we can construct  $Q$  so that  $Q[u, R^T]^T = [0, R_1^T]^T$ , where  $R_1$  is the modified factor.  $Q$  is constructed from a sequence of Givens rotations in order to zero the elements of  $u$ . Downdating is similar except that hyperbolic rotations have to be used in place of Givens rotations — see Golub and van Loan (2013, section 6.5.4) for details. Downdating only works if  $A - uu^T$  is positive definite. Again the computational cost is  $O(n^2)$ .

Note that the updates are vector oriented, and are hence not susceptible to speed up by use of an optimized BLAS. The updates are set up to be relatively Cache friendly, in that in the upper triangular case successive Givens rotations are stored for sequential application column-wise, rather than being applied row-wise as soon as they are computed. Even so, the upper triangular update is slightly slower than the lower triangular update.

**References**

Golub GH and CF Van Loan (2013) Matrix Computations (4th edition) Johns Hopkins

**Examples**

```

require(mgcv)
set.seed(0)
n <- 6
A <- crossprod(matrix(runif(n*n),n,n))
R0 <- chol(A)
k <- 3
Rd <- choldrop(R0,k)
range(Rd-chol(A[-k,-k]))
Rd;chol(A[-k,-k])

same but using lower triangular factor A = LL'
L <- t(R0)
Ld <- choldrop(L,k)
range(Ld-t(chol(A[-k,-k])))
Ld;t(chol(A[-k,-k]))

Rank one update example
u <- runif(n)
R <- cholup(R0,u,TRUE)
Ru <- chol(A+u %%% t(u)) ## direct for comparison
R;Ru
range(R-Ru)

Downdate - just going back from R to R0
Rd <- cholup(R,u,FALSE)
R0;Rd
range(R0-Rd)

```

choose.k

*Basis dimension choice for smooths***Description**

Choosing the basis dimension, and checking the choice, when using penalized regression smoothers.

Penalized regression smoothers gain computational efficiency by virtue of being defined using a basis of relatively modest size,  $k$ . When setting up models in the `mgcv` package, using `s` or `te` terms in a model formula,  $k$  must be chosen: the defaults are essentially arbitrary.

In practice  $k-1$  (or  $k$ ) sets the upper limit on the degrees of freedom associated with an `s` smooth (1 degree of freedom is usually lost to the identifiability constraint on the smooth). For `te` smooths the upper limit of the degrees of freedom is given by the product of the  $k$  values provided for each marginal smooth less one, for the constraint. However the actual effective degrees of freedom are controlled by the degree of penalization selected during fitting, by GCV, AIC, REML or whatever is specified. The exception to this is if a smooth is specified using the `fx=TRUE` option, in which case it is unpenalized.

So, exact choice of  $k$  is not generally critical: it should be chosen to be large enough that you are reasonably sure of having enough degrees of freedom to represent the underlying ‘truth’ reasonably well, but small enough to maintain reasonable computational efficiency. Clearly ‘large’ and ‘small’ are dependent on the particular problem being addressed.

As with all model assumptions, it is useful to be able to check the choice of  $k$  informally. If the effective degrees of freedom for a model term are estimated to be much less than  $k-1$  then this is unlikely to be very worthwhile, but as the EDF approach  $k-1$ , checking can be important. A useful general purpose approach goes as follows: (i) fit your model and extract the deviance residuals; (ii) for each smooth term in your model, fit an equivalent, single, smooth to the residuals, using a substantially increased  $k$  to see if there is pattern in the residuals that could potentially be explained by increasing  $k$ . Examples are provided below.

The obvious, but more costly, alternative is simply to increase the suspect  $k$  and refit the original model. If there are no statistically important changes as a result of doing this, then  $k$  was large enough. (Change in the smoothness selection criterion, and/or the effective degrees of freedom, when  $k$  is increased, provide the obvious numerical measures for whether the fit has changed substantially.)

`gam.check` runs a simple simulation based check on the basis dimensions, which can help to flag up terms for which  $k$  is too low. Grossly too small  $k$  will also be visible from partial residuals available with `plot.gam`.

One scenario that can cause confusion is this: a model is fitted with  $k=10$  for a smooth term, and the EDF for the term is estimated as 7.6, some way below the maximum of 9. The model is then refitted with  $k=20$  and the EDF increases to 8.7 - what is happening - how come the EDF was not 8.7 the first time around? The explanation is that the function space with  $k=20$  contains a larger subspace of functions with EDF 8.7 than did the function space with  $k=10$ : one of the functions in this larger subspace fits the data a little better than did any function in the smaller subspace. These subtleties seldom have much impact on the statistical conclusions to be drawn from a model fit, however.

## Examples

```
Simulate some data
library(mgcv)
set.seed(1)
dat <- gamSim(1,n=400,scale=2)

fit a GAM with quite low `k`
b<-gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),data=dat)
plot(b,pages=1,residuals=TRUE) ## hint of a problem in s(x2)

the following suggests a problem with s(x2)
gam.check(b)

Another approach (see below for more obvious method)....
check for residual pattern, removeable by increasing `k`
typically `k`, below, should be substantially larger than
the original, `k` but certainly less than n/2.
Note use of cheap "cs" shrinkage smoothers, and gamma=1.4
to reduce chance of overfitting...
rsd <- residuals(b)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
```

```

gam(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

refit...
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=20)+s(x3,k=6),data=dat)
gam.check(b) ## better

similar example with multi-dimensional smooth
b1 <- gam(y~s(x0)+s(x1,x2,k=15)+s(x3),data=dat)
rsd <- residuals(b1)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,x2,k=100,bs="ts"),gamma=1.4,data=dat) ## `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

gam.check(b1) ## shows same problem

and a `te' example
b2 <- gam(y~s(x0)+te(x1,x2,k=4)+s(x3),data=dat)
rsd <- residuals(b2)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~te(x1,x2,k=10,bs="cs"),gamma=1.4,data=dat) ## `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

gam.check(b2) ## shows same problem

same approach works with other families in the original model
dat <- gamSim(1,n=400,scale=.25,dist="poisson")
bp<-gam(y~s(x0,k=5)+s(x1,k=5)+s(x2,k=5)+s(x3,k=5),
 family=poisson,data=dat,method="ML")

gam.check(bp)

rsd <- residuals(bp)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

rm(dat)

More obvious, but more expensive tactic... Just increase
suspicious k until fit is stable.

set.seed(0)
dat <- gamSim(1,n=400,scale=2)
fit a GAM with quite low `k'
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),
 data=dat,method="REML")
b
edf for 3rd smooth is highest as proportion of k -- increase k
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=12)+s(x3,k=6),
 data=dat,method="REML")
b
edf substantially up, -ve REML substantially down
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=24)+s(x3,k=6),
 data=dat,method="REML")

```

```

b
slight edf increase and -ve REML change
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=40)+s(x3,k=6),
 data=dat,method="REML")
b
definitely stabilized (but really k around 20 would have been fine)

```

clog

*GAM censored logistic distribution family for log-logistic AFT models*

## Description

Family for use with `gam` or `bam`, implementing regression for censored logistic data. If  $y$  is the response with mean  $\mu$  and scale parameter  $s = w^{-1/2} \exp(\theta)$ , then  $y$  has p.d.f.

$$\frac{\exp\{-(y - \mu)/s\}}{s[1 + \exp\{-(y - \mu)/s\}]^2}.$$

$\theta$  is a single scalar for all observations. Observations may be left, interval or right censored or uncensored.

Useful for log-logistic accelerated failure time (AFT) models, for example.

## Usage

```
clog(theta=NULL,link="identity")
```

## Arguments

|       |                                                                                                                                                                                                                  |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| theta | log scale parameter. If supplied and positive then taken as a fixed value of standard deviation (not its log). If supplied and negative taken as negative of initial value for standard deviation (not its log). |
| link  | The link function: "identity", "log" or "sqrt".                                                                                                                                                                  |

## Details

If the family is used with a vector response, then it is assumed that there is no censoring, and a regular Gaussian regression results. If there is censoring then the response should be supplied as a two column matrix. The first column is always numeric. Entries in the second column are as follows.

- If an entry is identical to the corresponding first column entry, then it is an uncensored observation.
- If an entry is numeric and different to the first column entry then there is interval censoring. The first column entry is the lower interval limit and the second column entry is the upper interval limit.  $y$  is only known to be between these limits.
- If the second column entry is  $-\text{Inf}$  then the observation is left censored at the value of the entry in the first column. It is only known that  $y$  is less than or equal to the first column value.
- If the second column entry is  $\text{Inf}$  then the observation is right censored at the value of the entry in the first column. It is only known that  $y$  is greater than or equal to the first column value.

Any mixture of censored and uncensored data is allowed, but be aware that data consisting only of right and/or left censored data contain very little information.

**Value**

An object of class `extended.family`.

... compare this to ?cox.ph
```

---

cnorm

*GAM censored normal family for log-normal AFT and Tobit models*

---

**Description**

Family for use with `gam` or `bam`, implementing regression for censored normal data. If  $y$  is the response with mean  $\mu$  and standard deviation  $w^{-1/2} \exp(\theta)$ , then  $w^{1/2}(y - \mu) \exp(-\theta)$  follows an  $N(0, 1)$  distribution. That is

$$y \sim N(\mu, e^{2\theta} w^{-1}).$$

$\theta$  is a single scalar for all observations. Observations may be left, interval or right censored or uncensored.

Useful for log-normal accelerated failure time (AFT) models, Tobit regression, and crudely rounded data, for example.

**Usage**

```
cnorm(theta=NULL,link="identity")
```

**Arguments**

|       |                                                                                                                                                                                                                               |

---

columb

---

*Reduced version of Columbus OH crime data*

---

## Description

By district crime data from Columbus OH, together with polygons describing district shape. Useful for illustrating use of simple Markov Random Field smoothers.

## Usage

```

data(columb)
data(columb.polys)

```

**Format**

columb is a 49 row data frame with the following columns

**area** land area of district

**home.value** housing value in 1000USD.

**income** household income in 1000USD.

**crime** residential burglaries and auto thefts per 1000 households.

**open.space** measure of open space in district.

**district** code identifying district, and matching names(columb.polys).

columb.polys contains the polygons defining the areas in the format described below.

**Details**

The data frame columb relates to the districts whose boundaries are coded in columb.polys. columb.polys[[i]] is a 2 column matrix, containing the vertices of the polygons defining the boundary of the ith district. columb.polys[[2]] has an artificial hole inserted to illustrate how holes in districts can be spefified. Different polygons defining the boundary of a district are separated by NA rows in columb.polys[[1]], and a polygon enclosed within another is treated as a hole in that region (a hole should never come first). names(columb.polys) matches columb\$district (order unimportant).

**Source**

The data are adapted from the columbus example in the spdep package, where the original source is given as:

Anselin, Luc. 1988. Spatial econometrics: methods and models. Dordrecht: Kluwer Academic, Table 12.1 p. 189.

|------------|--------------------------------|
| concurvity | <i>GAM concurvity measures</i> |
|------------|--------------------------------|

---

**Description**

Produces summary measures of concurvity between [gam](#) components.

**Usage**

```
concurvity(b,full=TRUE)
```

**Arguments**

|      |                                                                                                                                                                                                                       |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| b    | An object inheriting from class "gam".                                                                                                                                                                                |
| full | If TRUE then concurvity of each term with the whole of the rest of the model is considered. If FALSE then pairwise concurvity measures between each smooth term (as well as the parametric component) are considered. |

## Details

Concurvity occurs when some smooth term in a model could be approximated by one or more of the other smooth terms in the model. This is often the case when a smooth of space is included in a model, along with smooths of other covariates that also vary more or less smoothly in space. Similarly it tends to be an issue in models including a smooth of time, along with smooths of other time varying covariates.

Concurvity can be viewed as a generalization of co-linearity, and causes similar problems of interpretation. It can also make estimates somewhat unstable (so that they become sensitive to apparently innocuous modelling details, for example).

This routine computes three related indices of concurvity, all bounded between 0 and 1, with 0 indicating no problem, and 1 indicating total lack of identifiability. The three indices are all based on the idea that a smooth term,  $f$ , in the model can be decomposed into a part,  $g$ , that lies entirely in the space of one or more other terms in the model, and a remainder part that is completely within the term's own space. If  $g$  makes up a large part of  $f$  then there is a concurvity problem. The indices used are all based on the square of  $\|g\|/\|f\|$ , that is the ratio of the squared Euclidean norms of the vectors of  $f$  and  $g$  evaluated at the observed covariate values.

The three measures are as follows

**worst** This is the largest value that the square of  $\|g\|/\|f\|$  could take for any coefficient vector. This is a fairly pessimistic measure, as it looks at the worst case irrespective of data. This is the only measure that is symmetric.

**observed** This just returns the value of the square of  $\|g\|/\|f\|$  according to the estimated coefficients. This could be a bit over-optimistic about the potential for a problem in some cases.

**estimate** This is the squared F-norm of the basis for  $g$  divided by the F-norm of the basis for  $f$ . It is a measure of the extent to which the  $f$  basis can be explained by the  $g$  basis. It does not suffer from the pessimism or potential for over-optimism of the previous two measures, but is less easy to understand.

## Value

If `full=TRUE` a matrix with one column for each term and one row for each of the 3 concurvity measures detailed below. If `full=FALSE` a list of 3 matrices, one for each of the three concurvity measures detailed below. Each row of the matrix relates to how the model terms depend on the model term supplying that rows name.

## Author(s)

Simon N. Wood <simon.wood@r-project.org>

## Examples

```
library(mgcv)
simulate data with concurvity...
set.seed(8); n <- 200
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
t <- sort(runif(n)) ## first covariate
make covariate x a smooth function of t + noise...
x <- f2(t) + rnorm(n)*3
simulate response dependent on t and x...
y <- sin(4*pi*t) + exp(x/20) + rnorm(n)*.3
```

```
fit model...
b <- gam(y ~ s(t,k=15) + s(x,k=15),method="REML")

assess concurvity between each term and `rest of model'...
concurvity(b)

... and now look at pairwise concurvity between terms...
concurvity(b,full=FALSE)
```

cox.ph

*Additive Cox Proportional Hazard Model*

## Description

The `cox.ph` family implements the Cox Proportional Hazards model with Peto's correction for ties, optional stratification, and estimation by penalized partial likelihood maximization, for use with `gam`. In the model formula, event time is the response. Under stratification the response has two columns: time and a numeric index for stratum. The `weights` vector provides the censoring information (0 for censoring, 1 for event). `cox.ph` deals with the case in which each subject has one event/censoring time and one row of covariate values. When each subject has several time dependent covariates see `cox.pht`.

See example below for conditional logistic regression.

## Usage

```
cox.ph(link="identity")
```

## Arguments

`link` currently (and possibly for ever) only "identity" supported.

## Details

Used with `gam` to fit Cox Proportional Hazards models to survival data. The model formula will have event/censoring times on the left hand side and the linear predictor specification on the right hand side. Censoring information is provided by the `weights` argument to `gam`, with 1 indicating an event and 0 indicating censoring.

Stratification is possible, allowing for different baseline hazards in different strata. In that case the response has two columns: the first is event/censoring time and the second is a numeric stratum index. See below for an example.

Prediction from the fitted model object (using the `predict` method) with `type="response"` will predict on the survivor function scale. This requires evaluation times to be provided as well as covariates (see example). Also see example code below for extracting the cumulative baseline hazard/survival directly. The `fitted.values` stored in the model object are survival function estimates for each subject at their event/censoring time.

`deviance`, `martingale`, `score`, or `schoenfeld` residuals can be extracted. See Klein and Moeschberger (2003) for descriptions. The score residuals are returned as a matrix of the same dimension as the model matrix, with a "terms" attribute, which is a list indicating which model matrix columns belong to which model terms. The score residuals are scaled. For parameteric terms this is by the standard deviation of associated model coefficient. For smooth terms the sub

matrix of score residuals for the term is postmultiplied by the transposed Cholesky factor of the covariance matrix for the term's coefficients. This is a transformation that makes the coefficients approximately independent, as required to make plots of the score residuals against event time interpretable for checking the proportional hazards assumption (see Klein and Moeschberger, 2003, p376). Penalization causes drift in the score residuals, which is also removed, to allow the residuals to be approximately interpreted as unpenalized score residuals. Schoenfeld and score residuals are computed by strata. See the examples for simple PH assumption checks by plotting score residuals, and Klein and Moeschberger (2003, section 11.4) for details. Note that high correlation between terms can undermine these checks.

Estimation of model coefficients is by maximising the log-partial likelihood penalized by the smoothing penalties. See e.g. Hastie and Tibshirani, 1990, section 8.3. for the partial likelihood used (with Peto's approximation for ties), but note that optimization of the partial likelihood does not follow Hastie and Tibshirani. See Klein and Moeschberger (2003) for estimation of residuals, the cumulative baseline hazard, survival function and associated standard errors (the survival standard error expression has a typo).

The percentage deviance explained reported for Cox PH models is based on the sum of squares of the deviance residuals, as the model deviance, and the sum of squares of the deviance residuals when the covariate effects are set to zero, as the null deviance. The same baseline hazard estimate is used for both.

This family deals efficiently with the case in which each subject has one event/censoring time and one row of covariate values. For studies in which there are multiple time varying covariate measures for each subject then the equivalent Poisson model should be fitted to suitable pseudodata using `bam(...,discrete=TRUE)`. See [cox.pht](#).

## Value

An object inheriting from class `general.family`.

conditional logistic regression models are often estimated using the
cox proportional hazards partial likelihood with a strata for each
case-control group. A dummy vector of times is created (all equal).
The following compares to 'clogit' for a simple case. Note that
the gam log likelihood is not exact if there is more than one case
per stratum, corresponding to clogit's approximate method.
library(survival);library(mgcv)
infert$dumt <- rep(1,nrow(infert))
mg <- gam(cbind(dumt,stratum) ~ spontaneous + induced, data=infert,
 family=cox.ph,weights=case)
ms <- clogit(case ~ spontaneous + induced + strata(stratum), data=infert,
 method="approximate")
summary(mg)$p.table[1:2,]; ms

cox.pht

*Additive Cox proportional hazard models with time varying covariates*

## Description

The `cox.ph` family only allows one set of covariate values per subject. If each subject has several time varying covariate measurements then it is still possible to fit a proportional hazards regression model, via an equivalent Poisson model. The recipe is provided by Whitehead (1980) and is equally valid in the smooth additive case. Its drawback is that the equivalent Poisson dataset can be quite large.

The trick is to generate an artificial Poisson observation for each subject in the risk set at each non-censored event time. The corresponding covariate values for each subject are whatever they are at the event time, while the Poisson response is zero for all subjects except those experiencing the event at that time (this corresponds to Peto's correction for ties). The linear predictor for the model must include an intercept for each event time (the cumulative sum of the exponential of these is the Breslow estimate of the baseline hazard).

Below is some example code employing this trick for the `pbcsseq` data from the `survival` package. It uses `bam` for fitting with the `discrete=TRUE` option for efficiency: there is some approximation involved in doing this, and the exact equivalent to what is done in `cox.ph` is rather obtained by using `gam` with `method="REML"` (taking many times the computational time for the example below). An alternative fits the model as a conditional logistic model using stratified Cox PH with event times as strata (see example). This would be identical in the unpenalized case, but smoothing parameter estimates can differ.

The function `tdpois` in the example code uses crude piecewise constant interpolation for the covariates, in which the covariate value at an event time is taken to be whatever it was the previous time that it was measured. Obviously more sophisticated interpolation schemes might be preferable.

lines(stepfun(te,c(1,exp(-H-se))),do.points=FALSE)
rug(pbcseq$day[pbcseq$id==25]) ## measurement times
```

cpois

*GAM censored Poisson family*

## Description

Family for use with [gam](#) or [bam](#), implementing regression for censored Poisson data. Observations may be left, interval or right censored or uncensored.

## Usage

```
cpois(link="log")
```

## Arguments

link                      The link function: "identity", "log" or "sqrt".

## Details

If the family is used with a vector response, then it is assumed that there is no censoring, and a regular Poisson regression results. If there is censoring then the response should be supplied as a two column matrix. The first column is always numeric. Entries in the second column are as follows.

- If an entry is identical to the corresponding first column entry, then it is an uncensored observation.

- If an entry is numeric and different to the first column entry then there is interval censoring. The first column entry is the lower interval limit and the second column entry is the upper interval limit (both should be non-integer).  $y$  is only known to be between these limits.
- If the second column entry is  $-\text{Inf}$  then the observation is left censored at the value of the entry (non-integer) in the first column. It is only known that  $y$  is below the first column value.
- If the second column entry is  $\text{Inf}$  then the observation is right censored at the value (non-integer) of the entry in the first column. It is only known that  $y$  is above the first column value.

Any mixture of censored and uncensored data is allowed, but be aware that data consisting only of right and/or left censored data contain very little information. It is strongly recommended to use non-integer values for censoring limits, to avoid any possibility of ambiguity. For example if  $y$  is known to be 3 or above, set the lower censoring limit to 2.5, or any other value in  $(2, 3)$ .

### Value

An object of class `extended.family`.

### Author(s)

|------------|---------------------------------------|
| cSplineDes | <i>Evaluate cyclic B spline basis</i> |
|------------|---------------------------------------|

---

**Description**

Uses splineDesign to set up the model matrix for a cyclic B-spline basis.

**Usage**

```
cSplineDes(x, knots, ord = 4, derivs=0)
```

**Arguments**

- x covariate values for smooth.
- knots The knot locations: the range of these must include all the data.
- ord order of the basis. 4 is a cubic spline basis. Must be >1.
- derivs order of derivative of the spline to evaluate, between 0 and ord-1. Recycled to length of x.

**Details**

The routine is a wrapper that sets up a B-spline basis, where the basis functions wrap at the first and last knot locations.

**Value**

A matrix with length(x) rows and length(knots)-1 columns.

**Author(s)**

| mu    | if $\eta$ is the linear predictor, $\mu = \text{inv\_link}(\eta)$ . In a traditional GAM $\mu = E(y)$ . |
| wt    | vector of weights.                                                                                      |
| theta | vector of family parameters that are not regression coefficients (e.g. scale parameters).               |
| fam   | the family object.                                                                                      |
| deriv | the order of derivative of the smoothing parameter score required.                                      |

## Value

A list of derivatives.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.

---

dpnorm

*Stable evaluation of difference between normal c.d.f.s*

---

**Description**

Evaluates the difference between two  $N(0, 1)$  cumulative distribution functions avoiding cancellation error.

**Usage**

```
dpnorm(x0, x1, log.p=FALSE)
```

**Arguments**

|       |                                                                                    |
|-------|------------------------------------------------------------------------------------|
| x0    | vector of lower values at which to evaluate standard normal distribution function. |
| x1    | vector of upper values at which to evaluate standard normal distribution function. |
| log.p | set to TRUE to compute on log scale, avoiding underflow.                           |

**Details**

Equivalent to  $\text{pnorm}(x1) - \text{pnorm}(x0)$ , but stable when  $x0$  and  $x1$  values are very close, or in the upper tail of the standard normal.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

```

### Usage

```
dppois(y0,y1,mu,log.p=TRUE)
```

### Arguments

|       |                                                                            |
|-------|----------------------------------------------------------------------------|
| y0    | vector of lower values at which to evaluate Poisson distribution function. |
| y1    | vector of upper values at which to evaluate Poisson distribution function. |
| mu    | vector giving Poisson means                                                |
| log.p | set to FALSE to compute on probability scale.                              |

### Details

Equivalent to  $\log(\text{ppois}(y1, \mu) - \text{ppois}(y0, \mu))$ , but stable when  $y0$  and  $y1$  are highly improbable and in the same tail of the distribution (avoids cancellation to  $\log(0)$ ).

### Author(s)

Simon N. Wood <simon.wood@r-project.org>

### Examples

```
require(mgcv)
n <- 10
mu <- rep(2,n)
y0 <- c(0:5,10,23,0,2)
y1 <- c(1:6,11,1000,100,40)
dppois(y0,y1,mu)
log(ppois(y1,mu)-ppois(y0,mu))
```

---

exclude.too.far

*Exclude prediction grid points too far from data*

---

### Description

Takes two arrays defining the nodes of a grid over a 2D covariate space and two arrays defining the location of data in that space, and returns a logical vector with elements TRUE if the corresponding node is too far from data and FALSE otherwise. Basically a service routine for `vis.gam` and `plot.gam`.

**Usage**

```
exclude.too.far(g1,g2,d1,d2,dist)
```

**Arguments**

|      |                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| g1   | co-ordinates of grid relative to first axis.                                                                                                                     |
| g2   | co-ordinates of grid relative to second axis.                                                                                                                    |
| d1   | co-ordinates of data relative to first axis.                                                                                                                     |
| d2   | co-ordinates of data relative to second axis.                                                                                                                    |
| dist | how far away counts as too far. Grid and data are first scaled so that the grid lies exactly in the unit square, and dist is a distance within this unit square. |

**Details**

Linear scalings of the axes are first determined so that the grid defined by the nodes in g1 and g2 lies exactly in the unit square (i.e. on [0,1] by [0,1]). These scalings are applied to g1, g2, d1 and d2. The minimum Euclidean distance from each node to a datum is then determined and if it is greater than dist the corresponding entry in the returned array is set to TRUE (otherwise to FALSE). The distance calculations are performed in compiled code for speed without storage overheads.

**Value**

A logical array with TRUE indicating a node in the grid defined by g1, g2 that is 'too far' from any datum.

**Examples**

```
library(mgcv)
x<-rnorm(100);y<-rnorm(100) # some "data"
n<-40 # generate a grid...
mx<-seq(min(x),max(x),length=n)
my<-seq(min(y),max(y),length=n)
gx<-rep(mx,n);gy<-rep(my,rep(n,n))
tf<-exclude.too.far(gx,gy,x,y,0.1)
plot(gx[!tf],gy[!tf],pch=".");points(x,y,col=2)
```

extract.lme.cov

*Extract the data covariance matrix from an lme object***Description**

This is a service routine for [gamm](#). Extracts the estimated covariance matrix of the data from an `lme` object, allowing the user control about which levels of random effects to include in this calculation. `extract.lme.cov` forms the full matrix explicitly: `extract.lme.cov2` tries to be more economical than this.

**Usage**

```
extract.lme.cov(b, data=NULL, start.level=1)
extract.lme.cov2(b, data=NULL, start.level=1)
```

**Arguments**

|                          |                                                                                                                                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>b</code>           | A fitted model object returned by a call to <a href="#">lme</a>                                                                                                                                                     |
| <code>.</code>           |                                                                                                                                                                                                                     |
| <code>data</code>        | The data frame/ model frame that was supplied to <a href="#">lme</a> , but with any rows removed by the na action dropped. Uses the data stored in the model object if not supplied.                                |
| <code>start.level</code> | The level of nesting at which to start including random effects in the calculation. This is used to allow smooth terms to be estimated as random effects, but treated like fixed effects for variance calculations. |

**Details**

The random effects, correlation structure and variance structure used for a linear mixed model combine to imply a covariance matrix for the response data being modelled. These routines extract that covariance matrix. The process is slightly complicated, because different components of the fitted model object are stored in different orders (see function code for details!).

The `extract.lme.cov` calculation is not optimally efficient, since it forms the full matrix, which may in fact be sparse. `extract.lme.cov2` is more efficient. If the covariance matrix is diagonal, then only the leading diagonal is returned; if it can be written as a block diagonal matrix (under some permutation of the original data) then a list of matrices defining the non-zero blocks is returned along with an index indicating which row of the original data each row/column of the block diagonal matrix relates to. The block sizes are defined by the coarsest level of grouping in the random effect structure.

[gamm](#) uses `extract.lme.cov2`.

`extract.lme.cov` does not currently deal with the situation in which the grouping factors for a correlation structure are finer than those for the random effects. `extract.lme.cov2` does deal with this situation.

**Value**

For `extract.lme.cov` an estimated covariance matrix.

For `extract.lme.cov2` a list containing the estimated covariance matrix and an indexing array. The covariance matrix is stored as the elements on the leading diagonal, a list of the matrices defining a block diagonal matrix, or a full matrix if the previous two options are not possible.

extract.lme.cov2(b)
```

---

factor.smooth

*Factor smooth interactions in GAMs*

---

**Description**

The interaction of one or more factors with a smooth effect, produces a separate smooth for each factor level. These smooths can have different smoothing parameters, or all have the same smoothing parameter. There are several ways to set them up.

**Factor by variables.** If the by variables for a smooth (specified using [s](#), [te](#), [ti](#) or [t2](#)) is a factor, then a separate smooth is produced for each factor level. If the factor is ordered, then no smooth is produced for its first level: this is useful for setting up models which have a reference level smooth and then difference to reference smooths for each factor level except the first (which is the reference). Giving the smooth an `id` forces the same smoothing parameter to be used for all levels of the factor. For example `s(x,by=fac,id=1)` would produce a separate smooth of `x` for each level of `fac`, with each smooth having the same smoothing parameter. See [gam.models](#) for more.

**Sum to zero smooth interactions** `bs="sz"` These factor smooth interactions are specified using `s(...,bs="sz")`. There may be several factors supplied, and a smooth is produced for each combination of factor levels. The smooths are constructed to exclude the ‘main effect’ smooth, or the effects of individual smooths produced for lower order combinations of factor levels. For example, with a single factor, the smooths for the different factor levels

are so constrained that the sum over all factor levels of equivalent spline coefficients are all zero. This allows the meaningful and identifiable construction of models with a main effect smooth plus smooths for the difference between each factor level and the main effect. Such a construction is often more natural than the by variable with ordered factors construction. See [smooth.construct.sz.smooth.spec](#).

**Random wiggly curves** `bs="fs"` This approach produces a smooth curve for each level of a single factor, treating the curves as entirely random. This means that in principle a model can be constructed with a main effect plus factor level smooth deviations from that effect. However the model is not forced to make the main effect do as much of the work as possible, in the way that the "sz" approach does. This approach can be very efficient with `gamm` as it exploits the nested estimation available in `lme`. See [smooth.construct.fs.smooth.spec](#).

### Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)> with input from Matteo Fasiolo.

### See Also

[smooth.construct.fs.smooth.spec](#), [smooth.construct.sz.smooth.spec](#)

### Examples

```
library(mgcv)
set.seed(0)
simulate data...
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x,a=2,b=-1) exp(a * x)+b
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
n <- 500;nf <- 25
fac <- sample(1:nf,n,replace=TRUE)
x0 <- runif(n);x1 <- runif(n);x2 <- runif(n)
a <- rnorm(nf)*.2 + 2;b <- rnorm(nf)*.5
f <- f0(x0) + f1(x1,a[fac],b[fac]) + f2(x2)
fac <- factor(fac)
y <- f + rnorm(n)*2
so response depends on global smooths of x0 and
x2, and a smooth of x1 for each level of fac.

fit model...
bm <- gamm(y~s(x0)+ s(x1,fac,bs="fs",k=5)+s(x2,k=20))
plot(bm$gam,pages=1)
summary(bm$gam)

bd <- bam(y~s(x0)+ s(x1) + s(x1,fac,bs="sz",k=5)+s(x2,k=20),discrete=TRUE)
plot(bd,pages=1)
summary(bd)

Could also use...
b <- gam(y~s(x0)+ s(x1,fac,bs="fs",k=5)+s(x2,k=20),method="ML")
... but its slower (increasingly so with increasing nf)
b <- gam(y~s(x0)+ t2(x1,fac,bs=c("tp","re"),k=5,full=TRUE)+
s(x2,k=20),method="ML")
... is exactly equivalent.
```

## Description

As well as the standard families (of class `family`) documented in [family](#) (see also [glm](#)) which can be used with functions [gam](#), [bam](#) and [gamm](#), `mgcv` also supplies some extra families, most of which are currently only usable with [gam](#), although some can also be used with [bam](#). These are described here.

## Details

The following families (class `family`) are in the exponential family given the value of a single parameter. They are usable with all modelling functions.

- [Tweedie](#) An exponential family distribution for which the variance of the response is given by the mean response to the power  $p$ .  $p$  is in (1,2) and must be supplied. Alternatively, see [tw](#) to estimate  $p$  (`gam/bam` only).
- [negbin](#) The negative binomial. Alternatively see [nb](#) to estimate the  $\theta$  parameter of the negative binomial (`gam/bam` only).

The following families (class `extended.family`) are for regression type models dependent on a single linear predictor, and with a log likelihood which is a sum of independent terms, each corresponding to a single response observation. Usable with [gam](#), with smoothing parameter estimation by "NCV", "REML" or "ML" (the latter does not integrate the unpenalized and parameteric effects out of the marginal likelihood optimized for the smoothing parameters). Also usable with [bam](#).

- [betar](#) for proportions data on (0,1) when the binomial is not appropriate.
- [cnorm](#) censored normal distribution, for log normal accelerated failure time models, Tobit regression and rounded data, for example.
- [bcg](#) Box-Cox transformed censored Gaussian.
- [clog](#) censored logistic distribution, for accelerated failure time models.
- [cpois](#) censored Poisson distribution.
- [nb](#) for negative binomial data when the  $\theta$  parameter is to be estimated.
- [ocat](#) for ordered categorical data.
- [scat](#) scaled t for heavy tailed data that would otherwise be modelled as Gaussian.
- [tw](#) for Tweedie distributed data, when the power parameter relating the variance to the mean is to be estimated.
- [ziP](#) for zero inflated Poisson data, when the zero inflation rate depends simply on the Poisson mean.

The above families of class `family` and `extended.family` can be combined to model data where different response observations come from different distributions. For example, when modelling the combination of presence-absence and abundance data, `binomial` and `nb` families might be used.

- [gfam](#) creates a 'grouped family' (or 'family group') from a list of families. The response is supplied as a two column matrix, the first containing the response observations, and the second an index of the family to which each observation relates.

The following families (class `general.family`) implement more general model classes. Usable only with `gam` and only with REML or NCV smoothing parameter estimation.

- `cox.ph` the Cox Proportional Hazards model for survival data (no NCV).
- `gammals` a gamma location-scale model, where the mean and standard deviation are modelled with separate linear predictors.
- `gaulss` a Gaussian location-scale model where the mean and the standard deviation are both modelled using smooth linear predictors.
- `gevlss` a generalized extreme value (GEV) model where the location, scale and shape parameters are each modelled using a linear predictor.
- `gumbls` a Gumbel location-scale model (2 linear predictors).
- `multinom`: multinomial logistic regression, for unordered categorical responses.
- `mvn`: multivariate normal additive models (no NCV).
- `shash` Sinh-arcsinh location scale and shape model family (4 linear predictors).
- `twlss` Tweedie location scale and variance power model family (3 linear predictors). Can only be fitted using EFS method.
- `ziplss` a ‘two-stage’ zero inflated Poisson model, in which ‘potential-presence’ is modelled with one linear predictor, and Poisson mean abundance given potential presence is modelled with a second linear predictor.

---

fix.family.link

---

*Modify families for use in GAM fitting and checking*

---

## Description

Generalized Additive Model fitting by ‘outer’ iteration, requires extra derivatives of the variance and link functions to be added to family objects. The first 3 functions add what is needed. Model checking can be aided by adding quantile and random deviate generating functions to the family. The final two functions do this.

## Usage

```
fix.family.link(fam)
fix.family.var(fam)
fix.family.ls(fam)
fix.family.qf(fam)
fix.family.rd(fam)
```

## Arguments

fam                      A family.

## Details

Consider the first 3 function first.

Outer iteration GAM estimation requires derivatives of the GCV, UBRE/gAIC, GACV, REML or ML score, which are obtained by finding the derivatives of the model coefficients w.r.t. the log smoothing parameters, using the implicit function theorem. The expressions for the derivatives require the second and third derivatives of the link w.r.t. the mean (and the 4th derivatives if Fisher scoring is not used). Also required are the first and second derivatives of the variance function w.r.t. the mean (plus the third derivative if Fisher scoring is not used). Finally REML or ML estimation

of smoothing parameters requires the log saturated likelihood and its first two derivatives w.r.t. the scale parameter. These functions add functions evaluating these quantities to a family.

If the family already has functions `dvar`, `d2var`, `d3var`, `d2link`, `d3link`, `d4link` and for RE/ML `ls`, then these functions simply return the family unmodified: this allows non-standard links to be used with `gam` when using outer iteration (performance iteration operates with unmodified families). Note that if you only need Fisher scoring then `d4link` and `d3var` can be dummy, as they are ignored. Similarly `ls` is only needed for RE/ML.

The `dvar` function is a function of a mean vector, `mu`, and returns a vector of corresponding first derivatives of the family variance function. The `d2link` function is also a function of a vector of mean values, `mu`: it returns a vector of second derivatives of the link, evaluated at `mu`. Higher derivatives are defined similarly.

If modifying your own family, note that you can often get away with supplying only a `dvar` and `d2var`, function if your family only requires links that occur in one of the standard families.

The second two functions are useful for investigating the distribution of residuals and are used by `qq.gam`. If possible the functions add quantile (`qf`) or random deviate (`rd`) generating functions to the family. If a family already has `qf` or `rd` functions then it is left unmodified. `qf` functions are only available for some families, and for quasi families neither type of function is available.

**Value**

A family object with extra component functions `dvar`, `d2var`, `d2link`, `d3link`, `d4link`, `ls`, and possibly `qf` and `rd`, depending on which functions are called. `fix.family.var` also adds a variable scale set to negative to indicate that family has a free scale parameter.

|                            |                                                            |
|----------------------------|------------------------------------------------------------|
| <code>fixDependence</code> | <i>Detect linear dependencies of one matrix on another</i> |
|----------------------------|------------------------------------------------------------|

---

**Description**

Identifies columns of a matrix `X2` which are linearly dependent on columns of a matrix `X1`. Primarily of use in setting up identifiability constraints for nested GAMs.

**Usage**

```
fixDependence(X1,X2,tol=.Machine$double.eps^.5,rank.def=0,strict=FALSE)
```

**Arguments**

|                  |                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------|
| <code>X1</code>  | A matrix.                                                                                              |
| <code>X2</code>  | A matrix, the columns of which may be partially linearly dependent on the columns of <code>X1</code> . |
| <code>tol</code> | The tolerance to use when assessing linear dependence.                                                 |

|          |                                                                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rank.def | If the degree of rank deficiency in X2, given X1, is known, then it can be supplied here, and tol is then ignored. Unused unless positive and not greater than the number of columns in X2. |
| strict   | if TRUE then only columns individually dependent on X1 are detected, if FALSE then enough columns to make the reduced X2 full rank and independent of X1 are detected.                      |

Details

The algorithm uses a simple approach based on QR decomposition: see Wood (2017, section 5.6.3) for details.

Value

A vector of the columns of X2 which are linearly dependent on columns of X1 (or which need to be deleted to acheive independence and full rank if strict==FALSE). NULL if the two matrices are independent.

Description

Description of [gam](#) formula (see Details), and how to extract it from a fitted gam object.

Usage

```
S3 method for class 'gam'
formula(x,...)
```

## Arguments

|                  |                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>x</code>   | fitted model objects of class <code>gam</code> (see <a href="#">gamObject</a> ) as produced by <code>gam()</code> . |
| <code>...</code> | un-used in this case                                                                                                |

## Details

`gam` will accept a formula or, with some families, a list of formulae. Other `mgcv` modelling functions will not accept a list. The list form provides a mechanism for specifying several linear predictors, and allows these to share terms: see below.

The formulae supplied to `gam` are exactly like those supplied to `glm` except that smooth terms, `s`, `te`, `ti` and `t2` can be added to the right hand side (and `.` is not supported in `gam` formulae).

Smooth terms are specified by expressions of the form:

```
s(x1, x2, ..., k=12, fx=FALSE, bs="tp", by=z, id=1)
```

where `x1`, `x2`, etc. are the covariates which the smooth is a function of, and `k` is the dimension of the basis used to represent the smooth term. If `k` is not specified then basis specific defaults are used. Note that these defaults are essentially arbitrary, and it is important to check that they are not so small that they cause oversmoothing (too large just slows down computation). Sometimes the modelling context suggests sensible values for `k`, but if not informal checking is easy: see [choose.k](#) and [gam.check](#).

`fx` is used to indicate whether or not this term should be unpenalized, and therefore have a fixed number of degrees of freedom set by `k` (almost always `k-1`). `bs` indicates the basis to use for the smooth: the built in options are described in [smooth.terms](#), and user defined smooths can be added (see [user.defined.smooth](#)). If `bs` is not supplied then the default "tp" ([tprs](#)) basis is used. `by` can be used to specify a variable by which the smooth should be multiplied. For example `gam(y~s(x, by=z))` would specify a model  $E(y) = f(x)z$  where  $f(\cdot)$  is a smooth function. The `by` option is particularly useful for models in which different functions of the same variable are required for each level of a factor and for 'varying coefficient models': see [gam.models](#). `id` is used to give smooths identities: smooths with the same identity have the same basis, penalty and smoothing parameter (but different coefficients, so they are different functions).

An alternative for specifying smooths of more than one covariate is e.g.:

```
te(x, z, bs=c("tp", "tp"), m=c(2, 3), k=c(5, 10))
```

which would specify a tensor product smooth of the two covariates `x` and `z` constructed from marginal t.p.r.s. bases of dimension 5 and 10 with marginal penalties of order 2 and 3. Any combination of basis types is possible, as is any number of covariates. [te](#) provides further information. [ti](#) terms are a variant designed to be used as interaction terms when the main effects (and any lower order interactions) are present. [t2](#) produces tensor product smooths that are the natural low rank analogue of smoothing spline anova models.

`s`, `te`, `ti` and `t2` terms accept an `sp` argument of supplied smoothing parameters: positive values are taken as fixed values to be used, negative to indicate that the parameter should be estimated. If `sp` is supplied then it over-rides whatever is in the `sp` argument to `gam`, if it is not supplied then it defaults to all negative, but does not over-ride the `sp` argument to `gam`.

Formulae can involve nested or "overlapping" terms such as

```
y~s(x)+s(z)+s(x, z) or y~s(x, z)+s(z, v)
```

but nested models should really be set up using [ti](#) terms: see [gam.side](#) for further details and examples.

Smooth terms in a `gam` formula will accept matrix arguments as covariates (and corresponding by variable), in which case a 'summation convention' is invoked. Consider the example of `s(X, Z, by=L)` where `X`, `Z` and `L` are `n` by `m` matrices. Let `F` be the `n` by `m` matrix that results from evaluating the smooth at the values in `X` and `Z`. Then the contribution to the linear predictor from the term will be `rowSums(F*L)` (note the element-wise multiplication). This convention allows the

linear predictor of the GAM to depend on (a discrete approximation to) any linear functional of a smooth: see [linear.functional.terms](#) for more information and examples (including functional linear models/signal regression).

Note that gam allows any term in the model formula to be penalized (possibly by multiple penalties), via the paraPen argument. See [gam.models](#) for details and example code.

When several formulae are provided in a list, then they can be used to specify multiple linear predictors for families for which this makes sense (e.g. [mvn](#)). The first formula in the list must include a response variable, but later formulae need not (depending on the requirements of the family). Let the linear predictors be indexed, 1 to d where d is the number of linear predictors, and the indexing is in the order in which the formulae appear in the list. It is possible to supply extra formulae specifying that several linear predictors should share some terms. To do this a formula is supplied in which the response is replaced by numbers specifying the indices of the linear predictors which will share the terms specified on the r.h.s. For example 1+3~s(x)+z-1 specifies that linear predictors 1 and 3 will share the terms s(x) and z (but we don't want an extra intercept, as this would usually be unidentifiable). Note that it is possible that a linear predictor only includes shared terms: it must still have its own formula, but the r.h.s. would simply be -1 (e.g. y ~ -1 or ~ -1). See [multinom](#) for an example.

Value

Returns the model formula, x\$formula. Provided so that anova methods print an appropriate description of the model.

WARNING

A gam formula should not refer to variables using e.g. dat[["x"]].

|-----------|-------------------------------------------------|
| formXtViX | <i>Form component of GAMM covariance matrix</i> |
|-----------|-------------------------------------------------|

---

Description

This is a service routine for [gamm](#). Given, *V*, an estimated covariance matrix obtained using [extract.lme.cov2](#) this routine forms a matrix square root of  $X^T V^{-1} X$  as efficiently as possible, given the structure of *V* (usually sparse).

Usage

formXtViX(V,X)

Arguments

- |   |                                                                              |
|---|------------------------------------------------------------------------------|
| V | A data covariance matrix list returned from <a href="#">extract.lme.cov2</a> |
| X | A model matrix.                                                              |

**Details**

The covariance matrix returned by `extract.lme.cov2` may be in a packed and re-ordered format, since it is usually sparse. Hence a special service routine is required to form the required products involving this matrix.

**Value**

A matrix, R such that `crossprod(R)` gives  $X^T V^{-1} X$ .

```
require(mgcv)
library(nlme)
data(ergoStool)
b <- lme(effort ~ Type, data=ergoStool, random=~1|Subject)
V1 <- extract.lme.cov(b, ergoStool)
V2 <- extract.lme.cov2(b, ergoStool)
X <- model.matrix(b, data=ergoStool)
crossprod(formXtViX(V2, X))
t(X)
```

---

fs.test

*FELSPLINE test function*

---

**Description**

Implements a finite area test function based on one proposed by Tim Ramsay (2002).

**Usage**

```
fs.test(x,y,r0=.1,r=.5,l=3,b=1,exclude=TRUE)
fs.boundary(r0=.1,r=.5,l=3,n.theta=20)
```

## Arguments

|         |                                                                                                                           |
|---------|---------------------------------------------------------------------------------------------------------------------------|
| x, y    | Points at which to evaluate the test function.                                                                            |
| r0      | The test domain is a sort of bent sausage. This is the radius of the inner bend                                           |
| r       | The radius of the curve at the centre of the sausage.                                                                     |
| l       | The length of an arm of the sausage.                                                                                      |
| b       | The rate at which the function increases per unit increase in distance along the centre line of the sausage.              |
| exclude | Should exterior points be set to NA?                                                                                      |
| n.theta | How many points to use in a piecewise linear representation of a quarter of a circle, when generating the boundary curve. |

## Details

The function details are not given in the source article: but this is pretty close. The function is modified from Ramsay (2002), in that it bulges, rather than being flat: this makes a better test of the smoother.

## Value

fs.test returns function evaluations, or NAs for points outside the boundary. fs.boundary returns a list of x, y points to be jointed up in order to define/draw the boundary.

plot the function, and its boundary...
fsb <- fs.boundary()
m<-300;n<-150
xm <- seq(-1,4,length=m);yn<-seq(-1,1,length=n)
xx <- rep(xm,n);yy<-rep(yn,rep(m,n))
tru <- matrix(fs.test(xx,yy),m,n) ## truth
image(xm,yn,tru,col=heat.colors(100),xlab="x",ylab="y")
lines(fsbx,fsby,lwd=3)
contour(xm,yn,tru,levels=seq(-5,5,by=.25),add=TRUE)
```

## Description

Fits a generalized additive model (GAM) to data, the term ‘GAM’ being taken to include any quadratically penalized GLM and a variety of other models estimated by a quadratically penalised likelihood type approach (see [family.mgcv](#)). The degree of smoothness of model terms is estimated as part of fitting. `gam` can also fit any GLM subject to multiple quadratic penalties (including estimation of degree of penalization). Confidence/credible intervals are readily available for any quantity predicted using a fitted model.

Smooth terms are represented using penalized regression splines (or similar smoothers) with smoothing parameters selected by GCV/UBRE/AIC/REML/NCV or by regression splines with fixed degrees of freedom (mixtures of the two are permitted). Multi-dimensional smooths are available using penalized thin plate regression splines (isotropic) or tensor product splines (when an isotropic smooth is inappropriate), and users can add smooths. Linear functionals of smooths can also be included in models. For an overview of the smooths available see [smooth.terms](#). For more on specifying models see [gam.models](#), [random.effects](#) and [linear.functional.terms](#). For more on model selection see [gam.selection](#). Do read [gam.check](#) and [choose.k](#).

See package `gam`, for GAMs via the original Hastie and Tibshirani approach (see details for differences to this implementation).

For very large datasets see [bam](#), for mixed GAM see [gamm](#) and [random.effects](#).

## Usage

```
gam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL,
 na.action, offset=NULL, method="GCV.Cp",
 optimizer=c("outer", "newton"), control=list(), scale=0,
 select=FALSE, knots=NULL, sp=NULL, min.sp=NULL, H=NULL, gamma=1,
 fit=TRUE, paraPen=NULL, G=NULL, in.out, drop.unused.levels=TRUE,
 drop.intercept=NULL, nei=NULL, discrete=FALSE, ...)
```

## Arguments

- |         |                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula | A GAM formula, or a list of formulae (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). These are exactly like the formula for a GLM except that smooth terms, <a href="#">s</a> , <a href="#">te</a> , <a href="#">ti</a> and <a href="#">t2</a> , can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these). |
| family  | This is a family object specifying the distribution and link to use in fitting etc (see <a href="#">glm</a> and <a href="#">family</a> ). See <a href="#">family.mgcv</a> for a full list of what is available, which goes well beyond exponential family. Note that quasi families actually result in the use of extended quasi-likelihood if method is set to a RE/ML method (McCullagh and Nelder, 1989, 9.6).             |
| data    | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>gam</code> is called.                                                                                                                                                                              |
| weights | prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to re-weight the contributions of each datum without                                                                                                                                                                                  |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. <code>weights &lt;- weights/mean(weights)</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>na.action</code> | a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>offset</code>    | Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula (this used to conform to the behaviour of <code>lm</code> and <code>glm</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>control</code>   | A list of fit control parameters to replace defaults returned by <code>gam.control</code> . Values not set assume default values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>method</code>    | The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "NCV" for neighbourhood cross-validation using the neighbourhood structure specified by <code>nei</code> ("QNCV" for numerically more robust version). "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Beyond the exponential family "REML" is the default, and the only other options are "ML", "NCV" or "QNCV". |
| <code>optimizer</code> | An array specifying the numerical optimization method to use to optimize the smoothing parameter estimation criterion (given by <code>method</code> ). "outer" for the direct nested optimization approach. "outer" can use several alternative optimizers, specified in the second element of <code>optimizer</code> : "newton" (default), "bfgs", "optim" or "nlm". "efs" for the extended Fellner Schall method of Wood and Fasiolo (2017).                                                                                                                                                                                                                               |
| <code>scale</code>     | If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.                                                                                                                                                                                                                                                                                                                                                           |
| <code>select</code>    | If this is TRUE then <code>gam</code> can add an extra penalty to each term so that it can be penalized to zero. This means that the smoothing parameter estimation that is part of fitting can completely remove terms from the model. If the corresponding smoothing parameter is estimated as zero then the extra penalty has no effect. Use <code>gamma</code> to increase level of penalization.                                                                                                                                                                                                                                                                        |
| <code>knots</code>     | this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the <code>k</code> value supplied (note that the number of knots is not always just <code>k</code> ). See <a href="#">tprs</a> for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.                                                                                                                                                                                                                           |
| <code>sp</code>        | A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters.                                                                                                                                                                                                                                      |
| <code>min.sp</code>    | Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters <code>full.sp</code> , in the returned object,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. `length(min.sp)` should always be the same as the total number of penalties (so it may be longer than `sp`, if smooths share smoothing parameters).

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| H                  | A user supplied fixed quadratic penalty on the parameters of the GAM can be supplied, with this as its coefficient matrix. A common use of this term is to add a ridge penalty to the parameters of the GAM in circumstances in which the model is close to un-identifiable on the scale of the linear predictor, but perfectly well defined on the response scale.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| gamma              | Increase this beyond 1 to produce smoother models. <code>gamma</code> multiplies the effective degrees of freedom in the GCV or UBRE/AIC. <code>n/gamma</code> can be viewed as an effective sample size in the GCV score, and this also enables it to be used with REML/ML. Ignored with P-RE/ML or the <code>efs</code> optimizer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| fit                | If this argument is TRUE then <code>gam</code> sets up the model and fits it, but if it is FALSE then the model is set up and an object <code>G</code> containing what would be required to fit is returned. See argument <code>G</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| paraPen            | optional list specifying any penalties to be applied to parametric model terms. <a href="#">gam.models</a> explains more.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| G                  | Usually NULL, but may contain the object returned by a previous call to <code>gam</code> with <code>fit=FALSE</code> , in which case all other arguments are ignored except for <code>sp</code> , <code>gamma</code> , <code>in.out</code> , <code>scale</code> , <code>control</code> , <code>method</code> optimizer and <code>fit</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| in.out             | optional list for initializing outer iteration. If supplied then this must contain two elements: <code>sp</code> should be an array of initialization values for all smoothing parameters (there must be a value for all smoothing parameters, whether fixed or to be estimated, but those for fixed s.p.s are not used); <code>scale</code> is the typical scale of the GCV/UBRE function, for passing to the outer optimizer, or the the initial value of the scale parameter, if this is to be estimated by RE/ML.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| drop.unused.levels | by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| drop.intercept     | Set to TRUE to force the model to really not have a constant in the parametric model part, even with factor variables present. Can be vector when formula is a list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| nei                | A list specifying the neighbourhood structure for NCV. <code>a</code> is the vector of indices to be dropped for each neighbourhood and <code>ma</code> gives the end of each neighbourhood. So <code>nei\$a[(nei\$ma[j-1]+1):nei\$ma[j]]</code> gives the points dropped for the neighbourhood <code>j</code> . <code>d</code> is the vector of indices of points to predict, with corresponding endpoints <code>md</code> . So <code>nei\$d[(nei\$md[j-1]+1):nei\$md[j]]</code> indexes the points to predict for neighbourhood <code>j</code> . If <code>nei==NULL</code> (or <code>a</code> or <code>ma</code> are missing) then leave-one-out cross validation is obtained. If <code>jackknife</code> is supplied then TRUE indicates to use raw jackknife covariances estimator and FALSE to use the conventional Bayes estimate. If not supplied then the estimator accounting for neighbourhood structure is used. <code>jackknife</code> ignored when <code>method</code> is not NCV. |
| discrete           | experimental option for setting up models for use with discrete methods employed in <a href="#">bam</a> . Do not modify.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ...                | further arguments for passing on e.g. to <code>gam.fit3</code> (such as <code>mustart</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Details

A generalized additive model (GAM) is a generalized linear model (GLM) in which the linear predictor is given by a user specified sum of smooth functions of the covariates plus a conventional parametric component of the linear predictor. A simple example is:

$$\log\{E(y_i)\} = \alpha + f_1(x_{1i}) + f_2(x_{2i})$$

where the (independent) response variables  $y_i \sim \text{Poi}$ , and  $f_1$  and  $f_2$  are smooth functions of covariates  $x_1$  and  $x_2$ . The log is an example of a link function. Note that to be identifiable the model requires constraints on the smooth functions. By default these are imposed automatically and require that the function sums to zero over the observed covariate values (the presence of a metric by variable is the only case which usually suppresses this).

If absolutely any smooth functions were allowed in model fitting then maximum likelihood estimation of such models would invariably result in complex over-fitting estimates of  $f_1$  and  $f_2$ . For this reason the models are usually fit by penalized likelihood maximization, in which the model (negative log) likelihood is modified by the addition of a penalty for each smooth function, penalizing its ‘wiggleness’. To control the trade-off between penalizing wiggleness and penalizing badness of fit each penalty is multiplied by an associated smoothing parameter: how to estimate these parameters, and how to practically represent the smooth functions are the main statistical questions introduced by moving from GLMs to GAMs.

The `mgcv` implementation of `gam` represents the smooth functions using penalized regression splines, and by default uses basis functions for these splines that are designed to be optimal, given the number basis functions used. The smooth terms can be functions of any number of covariates and the user has some control over how smoothness of the functions is measured.

`gam` in `mgcv` solves the smoothing parameter estimation problem by using the Generalized Cross Validation (GCV) criterion

$$nD/(n - DoF)^2$$

or an Un-Biased Risk Estimator (UBRE) criterion

$$D/n + 2sDoF/n - s$$

where  $D$  is the deviance,  $n$  the number of data,  $s$  the scale parameter and  $DoF$  the effective degrees of freedom of the model. Notice that UBRE is effectively just AIC rescaled, but is only used when  $s$  is known.

Alternatives are GACV, [NCV](#) or a Laplace approximation to REML. There is some evidence that the latter may actually be the most effective choice. The main computational challenge solved by the `mgcv` package is to optimize the smoothness selection criteria efficiently and reliably.

Broadly `gam` works by first constructing basis functions and one or more quadratic penalty coefficient matrices for each smooth term in the model formula, obtaining a model matrix for the strictly parametric part of the model formula, and combining these to obtain a complete model matrix (/design matrix) and a set of penalty matrices for the smooth terms. The linear identifiability constraints are also obtained at this point. The model is fit using `gam.fit3` or variants, which are modifications of `glm.fit`. The GAM penalized likelihood maximization problem is solved by Penalized Iteratively Re-weighted Least Squares (P-IRLS) (see e.g. Wood 2000). Smoothing parameter selection is possible in one of three ways. (i) ‘Performance iteration’ uses the fact that at each P-IRLS step a working penalized linear model is estimated, and the smoothing parameter estimation can be performed for each such working model. Eventually, in most cases, both model parameter estimates and smoothing parameter estimates converge. This option is available in `bam` and `gamm`. (ii) Alternatively the P-IRLS scheme is iterated to convergence for each trial set of smoothing parameters, and GCV, UBRE or REML scores are only evaluated on convergence - optimization is then ‘outer’ to the P-IRLS loop: in this case the P-IRLS iteration has to be differentiated, to facilitate optimization,

and [gam.fit3](#) or one of its variants is used. (iii) The extended Fellner-Schall algorithm of Wood and Fasiolo (2017) alternates estimation of model coefficients with simple updates of smoothing parameters, eventually approximately maximizing the marginal likelihood of the model (REML). `gam` uses the second method, outer iteration, by default.

Several alternative basis-penalty types are built in for representing model smooths, but alternatives can easily be added (see [smooth.terms](#) for an overview and [smooth.construct](#) for how to add smooth classes). The choice of the basis dimension ( $k$  in the `s`, `te`, `ti` and `t2` terms) is something that should be considered carefully (the exact value is not critical, but it is important not to make it restrictively small, nor very large and computationally costly). The basis should be chosen to be larger than is believed to be necessary to approximate the smooth function concerned. The effective degrees of freedom for the smooth will then be controlled by the smoothing penalty on the term, and (usually) selected automatically (with an upper limit set by  $k-1$  or occasionally  $k$ ). Of course the  $k$  should not be made too large, or computation will be slow (or in extreme cases there will be more coefficients to estimate than there are data).

Note that `gam` assumes a very inclusive definition of what counts as a GAM: basically any penalized GLM can be used: to this end `gam` allows the non smooth model components to be penalized via argument `paraPen` and allows the linear predictor to depend on general linear functionals of smooths, via the summation convention mechanism described in [linear.functional.terms](#). `link{family.mgcv}` details what is available beyond GLMs and the exponential family.

Details of the default underlying fitting methods are given in Wood (2011, 2004) and Wood, Pya and Saefken (2016). Some alternative methods are discussed in Wood (2000, 2017).

`gam()` is not a clone of Trevor Hastie's original (as supplied in S-PLUS or package `gam`). The major differences are (i) that by default estimation of the degree of smoothness of model terms is part of model fitting, (ii) a Bayesian approach to variance estimation is employed that makes for easier confidence interval calculation (with good coverage probabilities), (iii) that the model can depend on any (bounded) linear functional of smooth terms, (iv) the parametric part of the model can be penalized, (v) simple random effects can be incorporated, and (vi) the facilities for incorporating smooths of more than one variable are different: specifically there are no `lo` smooths, but instead (a) `s` terms can have more than one argument, implying an isotropic smooth and (b) `te`, `ti` or `t2` smooths are provided as an effective means for modelling smooth interactions of any number of variables via scale invariant tensor product smooths. Splines on the sphere, Duchon splines and Gaussian Markov Random Fields are also available. (vii) Models beyond the exponential family are available. See package `gam`, for GAMs via the original Hastie and Tibshirani approach.

## Value

If `fit=FALSE` the function returns a list `G` of items needed to fit a GAM, but doesn't actually fit it.

Otherwise the function returns an object of class `"gam"` as described in [gamObject](#).

## WARNINGS

The default basis dimensions used for smooth terms are essentially arbitrary, and it should be checked that they are not too small. See [choose.k](#) and [gam.check](#).

Automatic smoothing parameter selection is not likely to work well when fitting models to very few response data.

For data with many zeroes clustered together in the covariate space it is quite easy to set up GAMs which suffer from identifiability problems, particularly when using Poisson or binomial families. The problem is that with e.g. log or logit links, mean value zero corresponds to an infinite range on the linear predictor scale.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

Front end design inspired by the S function of the same name based on the work of Hastie and Tibshirani (1990). Underlying methods owe much to the work of Wahba (e.g. 1990) and Gu (e.g. 2002).

random effects and tricks for large binary datasets)

library(mgcv)
set.seed(2) ## simulate some data...
dat <- gamSim(1,n=400,dist="normal",scale=2)
b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
summary(b)
plot(b,pages=1,residuals=TRUE) ## show partial residuals
plot(b,pages=1,seWithMean=TRUE) ## `with intercept' CIs

plot derivaives of smooths w.r.t. covariates - the
direct analogue of linear model regression coefficients
- also selecting a more colourful plotting scheme...
plot(b,pages=1,scale=0,deriv=TRUE,scheme=2)

run some basic model checks, including checking
smoothing basis dimensions...
gam.check(b)

same fit in two parts
G <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),fit=FALSE,data=dat)
b <- gam(G=G)
print(b)

2 part fit enabling manipulation of smoothing parameters...
G <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),fit=FALSE,data=dat,sp=b$sp)
G$lspl0 <- log(b$sp*10) ## provide log of required sp vec
gam(G=G) ## it's smoother

change the smoothness selection method to REML
b0 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat,method="REML")
use alternative plotting scheme, and way intervals include
smoothing parameter uncertainty...
plot(b0,pages=1,scheme=1,unconditional=TRUE)
```

```

Would a smooth interaction of x0 and x1 be better?
Use tensor product smooth of x0 and x1, basis
dimension 49 (see ?te for details, also ?t2).
bt <- gam(y~te(x0,x1,k=7)+s(x2)+s(x3),data=dat,
 method="REML")
plot(bt,pages=1)
plot(bt,pages=1,scheme=2) ## alternative visualization
AIC(b0,bt) ## interaction worse than additive

Alternative: test for interaction with a smooth ANOVA
decomposition (this time between x2 and x1)
bt <- gam(y~s(x0)+s(x1)+s(x2)+s(x3)+ti(x1,x2,k=6),
 data=dat,method="REML")
summary(bt)

If it is believed that x0 and x1 are naturally on
the same scale, and should be treated isotropically
then could try...
bs <- gam(y~s(x0,x1,k=40)+s(x2)+s(x3),data=dat,
 method="REML")
plot(bs,pages=1)
AIC(b0,bt,bs) ## additive still better.

Now do automatic terms selection as well
b1 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat,
 method="REML",select=TRUE)
plot(b1,pages=1)

set the smoothing parameter for the first term, estimate rest ...
bp <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),sp=c(0.01,-1,-1,-1),data=dat)
plot(bp,pages=1,scheme=1)
alternatively...
bp <- gam(y~s(x0,sp=.01)+s(x1)+s(x2)+s(x3),data=dat)

set lower bounds on smoothing parameters
bp<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),
 min.sp=c(0.001,0.01,0,10),data=dat)
print(b);print(bp)

same with REML
bp<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),
 min.sp=c(0.1,0.1,0,10),data=dat,method="REML")
print(b0);print(bp)

now a GAM with 3df regression spline term & 2 penalized terms

b0 <- gam(y~s(x0,k=4,fx=TRUE,bs="tp")+s(x1,k=12)+s(x2,k=15),data=dat)
plot(b0,pages=1)

now simulate poisson data...
set.seed(6)
dat <- gamSim(1,n=2000,dist="poisson",scale=.1)

```

```

use "cr" basis to save time, with 2000 data...
b2<-gam(y~s(x0,bs="cr")+s(x1,bs="cr")+s(x2,bs="cr")+
 s(x3,bs="cr"),family=poisson,data=dat,method="REML")
plot(b2,pages=1)

drop x3, but initialize sp's from previous fit, to
save more time...

b2a<-gam(y~s(x0,bs="cr")+s(x1,bs="cr")+s(x2,bs="cr"),
 family=poisson,data=dat,method="REML",
 in.out=list(sp=b2$sp[1:3],scale=1))
par(mfrow=c(2,2))
plot(b2a)

par(mfrow=c(1,1))
similar example using GACV...

vis.gam(b7,theta=30,phi=30)
detach(eg)

```

## Description

Takes a fitted gam object produced by `gam()` and produces some diagnostic information about the fitting procedure and results. The default is to produce 4 residual plots, some information about the

convergence of the smoothness selection optimization, and to run diagnostic tests of whether the basis dimension choices are adequate. Care should be taken in interpreting the results when applied to gam objects returned by [gamm](#).

## Usage

```
gam.check(b, old.style=FALSE,
 type=c("deviance", "pearson", "response"),
 k.sample=5000, k.rep=200,
 rep=0, level=.9, r1.col=2, rep.col="gray80", ...)
```

## Arguments

|                                          |                                                                                               |

## Details

Checking a fitted gam is like checking a fitted glm, with two main differences. Firstly, the basis dimensions used for smooth terms need to be checked, to ensure that they are not so small that they force oversmoothing: the defaults are arbitrary. [choose.k](#) provides more detail, but the diagnostic tests described below and reported by this function may also help. Secondly, fitting may not always be as robust to violation of the distributional assumptions as would be the case for a regular GLM, so slightly more care may be needed here. In particular, the theory of quasi-likelihood implies that if the mean variance relationship is OK for a GLM, then other departures from the assumed distribution are not problematic: GAMs can sometimes be more sensitive. For example, un-modelled overdispersion will typically lead to overfit, as the smoothness selection criterion tries to reduce the scale parameter to the one specified. Similarly, it is not clear how sensitive REML and ML smoothness selection will be to deviations from the assumed response distribution. For these reasons this routine uses an enhanced residual QQ plot.

This function plots 4 standard diagnostic plots, some smoothing parameter estimation convergence information and the results of tests which may indicate if the smoothing basis dimension for a term is too low.

Usually the 4 plots are various residual plots. For the default optimization methods the convergence information is summarized in a readable way, but for other optimization methods, whatever is returned by way of convergence diagnostics is simply printed.

The test of whether the basis dimension for a smooth is adequate (Wood, 2017, section 5.9) is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the k-index reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The p-value is computed by simulation: the residuals are randomly re-shuffled `k.rep` times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than `k.sample` data, the tests are based on `k.sample` randomly sampled data. Low p-values may indicate that the basis

dimension,  $k$ , has been set too low, especially if the reported edf is close to  $k$ , the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated p-values will of course vary widely from one replicate to the next. Currently smooths of factor variables are not supported and will give an NA p-value.

Doubling a suspect  $k$  and re-fitting is sensible: if the reported edf increases substantially then you may have been missing something in the first fit. Of course p-values can be low for reasons other than a too low  $k$ . See [choose.k](#) for fuller discussion.

The QQ plot produced is usually created by a call to [qq.gam](#), and plots deviance residuals against approximate theoretical quantiles of the deviance residual distribution, according to the fitted model. If this looks odd then investigate further using [qq.gam](#). Note that residuals for models fitted to binary data contain very little information useful for model checking (it is necessary to find some way of aggregating them first), so the QQ plot is unlikely to be useful in this case.

Take care when interpreting results from applying this function to a model fitted using [gamm](#). In this case the returned gam object is based on the working model used for estimation, and will treat all the random effects as part of the error. This means that the residuals extracted from the gam object are not standardized for the family used or for the random effects or correlation structure. Usually it is necessary to produce your own residual checks based on consideration of the model structure you have used.

## Value

A vector of reference quantiles for the residual distribution, if these can be computed.

## Examples

```
library(mgcv)
set.seed(0)
dat <- gamSim(1,n=200)
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
plot(b,pages=1)
gam.check(b,pch=19,cex=.3)
```

gam.control

*Setting GAM fitting defaults***Description**

This is an internal function of package `mgcv` which allows control of the numerical options for fitting a GAM. Typically users will want to modify the defaults if model fitting fails to converge, or if the warnings are generated which suggest a loss of numerical stability during fitting. To change the default choice of fitting method, see [gam](#) arguments method and optimizer.

**Usage**

```
gam.control(nthreads=1,ncv.threads=1,irls.reg=0.0,epsilon = 1e-07,
 maxit = 200,mgcv.tol=1e-7,mgcv.half=15, trace = FALSE,
 rank.tol=.Machine$double.eps^0.5,nlm=list(),
 optim=list(),newton=list(),
 idlinksBases=TRUE,scalePenalty=TRUE,efs.lspmax=15,
 efs.tol=.1,keepData=FALSE,scale.est="fletcher",
 edge.correct=FALSE)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nthreads</code>    | Some parts of some smoothing parameter selection methods (e.g. REML) can use some parallelization in the C code if your R installation supports openMP, and <code>nthreads</code> is set to more than 1. Note that it is usually better to use the number of physical cores here, rather than the number of hyper-threading cores.                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>ncv.threads</code> | The computations for neighbourhood cross-validation (NCV) typically scale better than the rest of the GAM computations and are worth parallelizing. <code>ncv.threads</code> allows you to set the number of threads to use separately.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>irls.reg</code>    | For most models this should be 0. The iteratively re-weighted least squares method by which GAMs are fitted can fail to converge in some circumstances. For example, data with many zeroes can cause problems in a model with a log link, because a mean of zero corresponds to an infinite range of linear predictor values. Such convergence problems are caused by a fundamental lack of identifiability, but do not show up as lack of identifiability in the penalized linear model problems that have to be solved at each stage of iteration. In such circumstances it is possible to apply a ridge regression penalty to the model to impose identifiability, and <code>irls.reg</code> is the size of the penalty. |
| <code>epsilon</code>     | This is used for judging convergence of the GLM IRLS loop in <a href="#">gam.fit3</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>maxit</code>       | Maximum number of IRLS iterations to perform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>mgcv.tol</code>    | The convergence tolerance parameter to use in GCV/UBRE optimization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>mgcv.half</code>   | If a step of the GCV/UBRE optimization method leads to a worse GCV/UBRE score, then the step length is halved. This is the number of halvings to try before giving up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>trace</code>       | Set this to TRUE to turn on diagnostic output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>rank.tol</code>    | The tolerance used to estimate the rank of the fitting problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>nlm</code>         | list of control parameters to pass to <a href="#">nlm</a> if this is used for outer estimation of smoothing parameters (not default). See details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| optim        | list of control parameters to pass to <a href="#">optim</a> if this is used for outer estimation of smoothing parameters (not default). See details.                                                                                                                                                                                                                                                                                 |
| newton       | list of control parameters to pass to default Newton optimizer used for outer estimation of log smoothing parameters. See details.                                                                                                                                                                                                                                                                                                   |
| idLinksBases | If smooth terms have their smoothing parameters linked via the id mechanism (see <a href="#">s</a> ), should they also have the same bases. Set this to FALSE only if you are sure you know what you are doing (you should almost surely set scalePenalty to FALSE as well in this case).                                                                                                                                            |
| scalePenalty | <a href="#">gamm</a> is somewhat sensitive to the absolute scaling of the penalty matrices of a smooth relative to its model matrix. This option rescales the penalty matrices to accomodate this problem. Probably should be set to FALSE if you are linking smoothing parameters but have set idLinkBases to FALSE.                                                                                                                |
| efs.lspmax   | maximum log smoothing parameters to allow under extended Fellner Schall smoothing parameter optimization.                                                                                                                                                                                                                                                                                                                            |
| efs.tol      | change in REML to count as negligible when testing for EFS convergence. If the step is small and the last 3 steps led to a REML change smaller than this, then stop.                                                                                                                                                                                                                                                                 |
| keepData     | Should a copy of the original data argument be kept in the gam object? Strict compatibility with class glm would keep it, but it wastes space to do so.                                                                                                                                                                                                                                                                              |
| scale.est    | How to estimate the scale parameter for exponential family models estimated by outer iteration. See <a href="#">gam.scale</a> .                                                                                                                                                                                                                                                                                                      |
| edge.correct | With RE/ML smoothing parameter selection in gam using the default Newton RE/ML optimizer, it is possible to improve inference at the ‘completely smooth’ edge of the smoothing parameter space, by decreasing smoothing parameters until there is a small increase in the negative RE/ML (e.g. 0.02). Set to TRUE or to a number representing the target increase to use. Only changes the corrected smoothing parameter matrix, Vc. |

## Details

Outer iteration using [newton](#) is controlled by the list [newton](#) with the following elements: [conv.tol](#) (default 1e-6) is the relative convergence tolerance; [maxNstep](#) is the maximum length allowed for an element of the Newton search direction (default 5); [maxSstep](#) is the maximum length allowed for an element of the steepest descent direction (only used if Newton fails - default 2); [maxHalf](#) is the maximum number of step halvings to permit before giving up (default 30).

If outer iteration using [nlm](#) is used for fitting, then the control list [nlm](#) stores control arguments for calls to routine [nlm](#). The list has the following named elements: (i) [ndigit](#) is the number of significant digits in the GCV/UBRE score - by default this is worked out from [epsilon](#); (ii) [gradtol](#) is the tolerance used to judge convergence of the gradient of the GCV/UBRE score to zero - by default set to 10\*[epsilon](#); (iii) [stepmax](#) is the maximum allowable log smoothing parameter step - defaults to 2; (iv) [steptol](#) is the minimum allowable step length - defaults to 1e-4; (v) [iterlim](#) is the maximum number of optimization steps allowed - defaults to 200; (vi) [check.analyticals](#) indicates whether the built in exact derivative calculations should be checked numerically - defaults to FALSE. Any of these which are not supplied and named in the list are set to their default values.

Outer iteration using [optim](#) is controlled using list [optim](#), which currently has one element: [factr](#) which takes default value 1e7.

## Description

When fitting GAMs there is a tradeoff between speed of fitting and probability of fit convergence. The fitting methods used by [gam](#) opt for certainty of convergence over speed of fit. [bam](#) opts for speed.

[gam](#) uses a nested iteration method (see [gam.outer](#)), in which each trial set of smoothing parameters proposed by an outer Newton algorithm require an inner Newton algorithm (penalized iteratively re-weighted least squares, PIRLS) to find the corresponding best fit model coefficients. Implicit differentiation is used to find the derivatives of the coefficients with respect to log smoothing parameters, so that the derivatives of the smoothness selection criterion can be obtained, as required by the outer iteration. This approach is less expensive than it at first appears, since excellent starting values for the inner iteration are available as soon as the smoothing parameters start to converge. See Wood (2011) and Wood, Pya and Saefken (2016).

[bam](#) uses an alternative approach similar to ‘performance iteration’ or ‘PQL’. A single PIRLS iteration is run to find the model coefficients. At each step this requires the estimation of a working penalized linear model. Smoothing parameter selection is applied directly to this working model at each step (as if it were a Gaussian additive model). This approach is more straightforward to code and in principle less costly than the nested approach. However it is not guaranteed to converge, since the smoothness selection criterion is changing at each iteration. It is sometimes possible for the algorithm to cycle around a small set of smoothing parameter, coefficient combinations without ever converging. [bam](#) includes some checks to limit this behaviour, and the further checks in the algorithm used by `bam(..., discrete=TRUE)` actually guarantee convergence in some cases, but in general guarantees are not possible. See Wood, Goude and Shaw (2015) and Wood et al. (2017).

[gam](#) when used with ‘general’ families (such as [multinom](#) or `cox.ph`) can also use a potentially faster scheme based on the extended Fellner-Schall method (Wood and Fasiolo, 2017). This also operates with a single iteration and is not guaranteed to converge, theoretically.

There are three things that you can try to speed up GAM fitting. (i) if you have large numbers of smoothing parameters in the generalized case, then try the “bfgs” method option in [gam](#) argument optimizer: this can be faster than the default. (ii) Try using [bam](#) (iii) For large datasets it may be worth changing the smoothing basis to use `bs="cr"` (see [s](#) for details) for 1-d smooths, and to use [te](#) smooths in place of [s](#) smooths for smooths of more than one variable. This is because the default thin plate regression spline basis “tp” is costly to set up for large datasets.

If you have convergence problems, it’s worth noting that a GAM is just a (penalized) GLM and the IRLS scheme used to estimate GLMs is not guaranteed to converge. Hence non convergence of a GAM may relate to a lack of stability in the basic IRLS scheme. Therefore it is worth trying to

establish whether the IRLS iterations are capable of converging. To do this fit the problematic GAM with all smooth terms specified with `fx=TRUE` so that the smoothing parameters are all fixed at zero. If this ‘largest’ model can converge then, then the maintainer would quite like to know about your problem! If it doesn’t converge, then its likely that your model is just too flexible for the IRLS process itself. Having tried increasing `maxit` in `gam.control`, there are several other possibilities for stabilizing the iteration. It is possible to try (i) setting lower bounds on the smoothing parameters using the `min.sp` argument of `gam`: this may or may not change the model being fitted; (ii) reducing the flexibility of the model by reducing the basis dimensions `k` in the specification of `s` and `te` model terms: this obviously changes the model being fitted somewhat.

Usually, a major contributor to fitting difficulties is that the model is a very poor description of the data.

Please report convergence problems, especially if you there is no obvious pathology in the data/model that suggests convergence should fail.

### Description

This is a deprecated internal function of package `mgcv`. It is a modification of the function `glm.fit`, designed to be called from `gam` when performance iteration is selected (not the default). The major modification is that rather than solving a weighted least squares problem at each IRLS step, a weighted, penalized least squares problem is solved at each IRLS step with smoothing parameters associated with each penalty chosen by GCV or UBRE, using routine `magic`. For further information on usage see code for `gam`. Some regularization of the IRLS weights is also permitted as a way of addressing identifiability related problems (see `gam.control`). Negative binomial parameter estimation is supported.

The basic idea of estimating smoothing parameters at each step of the P-IRLS is due to Gu (1992), and is termed ‘performance iteration’ or ‘performance oriented iteration’.

### Usage

```
gam.fit(G, start = NULL, etastart = NULL,
 mustart = NULL, family = gaussian(),
 control = gam.control(), gamma=1,
 fixedSteps=(control$maxit+1),...)
```

### Arguments

|            |                                                                                                                       |

## Description

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC, GCV, GACV, REML or ML score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine estimates a GAM (any quadratically penalized GLM) given log smoothing parameters, and evaluates derivatives of the smoothness selection scores of the model with respect to the log smoothing parameters. Calculation of exact derivatives is generally faster than approximating them by finite differencing, as well as generally improving the reliability of GCV/UBRE/AIC/REML score minimization.

The approach is to run the P-IRLS to convergence, and only then to iterate for first and second derivatives.

Not normally called directly, but rather service routines for [gam](#).

## Usage

```
gam.fit3(x, y, sp, Eb, UrS=list(),
 weights = rep(1, nobs), start = NULL, etastart = NULL,
 mustart = NULL, offset = rep(0, nobs), U1 = diag(ncol(x)),
 Mp = -1, family = gaussian(), control = gam.control(),
 intercept = TRUE, deriv=2, gamma=1, scale=1,
 printWarn=TRUE, scoreType="REML", null.coef=rep(0, ncol(x)),
 pearson.extra=0, dev.extra=0, n.true=-1, S1=NULL, nei=NULL, ...)
```

## Arguments

|          |                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------|
| x        | The model matrix for the GAM (or any penalized GLM).                                                 |
| y        | The response variable.                                                                               |
| sp       | The log smoothing parameters.                                                                        |
| Eb       | A balanced version of the total penalty matrix: used for numerical rank determination.               |
| UrS      | List of square root penalties premultiplied by transpose of orthogonal basis for the total penalty.  |
| weights  | prior weights for fitting.                                                                           |
| start    | optional starting parameter guesses.                                                                 |
| etastart | optional starting values for the linear predictor.                                                   |
| mustart  | optional starting values for the mean.                                                               |
| offset   | the model offset                                                                                     |
| U1       | An orthogonal basis for the range space of the penalty — required for ML smoothness estimation only. |
| Mp       | The dimension of the total penalty null space — required for ML smoothness estimation only.          |

|               |                                                                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| family        | the family - actually this routine would never be called with gaussian()                                                                                                                         |
| control       | control list as returned from <a href="#">glm.control</a>                                                                                                                                        |
| intercept     | does the model have an intercept, TRUE or FALSE                                                                                                                                                  |
| deriv         | Should derivatives of the GCV and UBRE/AIC scores be calculated? 0, 1 or 2, indicating the maximum order of differentiation to apply.                                                            |
| gamma         | The weight given to each degree of freedom in the GCV and UBRE scores can be varied (usually increased) using this parameter.                                                                    |
| scale         | The scale parameter - needed for the UBRE/AIC score.                                                                                                                                             |
| printWarn     | Set to FALSE to suppress some warnings. Useful in order to ensure that some warnings are only printed if they apply to the final fitted model, rather than an intermediate used in optimization. |
| scoreType     | specifies smoothing parameter selection criterion to use.                                                                                                                                        |
| null.coef     | coefficients for a model which gives some sort of upper bound on deviance. This allows immediate divergence problems to be controlled.                                                           |
| pearson.extra | Extra component to add to numerator of pearson statistic in P-REML/P-ML smoothness selection criteria.                                                                                           |
| dev.extra     | Extra component to add to deviance for REML/ML type smoothness selection criteria.                                                                                                               |
| n.true        | Number of data to assume in smoothness selection criteria. <=0 indicates that it should be the number of rows of X.                                                                              |
| S1            | A smooth list suitable for passing to gam.fit5.                                                                                                                                                  |
| nei           | List specifying neighbourhood structure if NCV used. See <a href="#">gam</a> .                                                                                                                   |
| ...           | Other arguments: ignored.                                                                                                                                                                        |

### Details

This routine is basically [glm.fit](#) with some modifications to allow (i) for quadratic penalties on the log likelihood; (ii) derivatives of the model coefficients with respect to log smoothing parameters to be obtained by use of the implicit function theorem and (iii) derivatives of the GAM GCV, UBRE/AIC, REML or ML scores to be evaluated at convergence.

In addition the routines apply step halving to any step that increases the penalized deviance substantially.

The most costly parts of the calculations are performed by calls to compiled C code (which in turn calls LAPACK routines) in place of the compiled code that would usually perform least squares estimation on the working model in the IRLS iteration.

Estimation of smoothing parameters by optimizing GCV scores obtained at convergence of the P-IRLS iteration was proposed by O'Sullivan et al. (1986), and is here termed 'outer' iteration.

Note that use of non-standard families with this routine requires modification of the families as described in [fix.family.link](#).

## Description

INTERNAL function for post-processing the output of `gam.fit5`.

## Usage

```
gam.fit5.post.proc(object, S1, L, lsp0, S, off, gamma)
```

## Arguments

|                     |                                                       |
|---------------------|-------------------------------------------------------|
| <code>object</code> | output of <code>gam.fit5</code> .                     |
| <code>S1</code>     | penalty object, output of <code>S1.setup</code> .     |
| <code>L</code>      | matrix mapping the working smoothing parameters.      |
| <code>lsp0</code>   | log smoothing parameters.                             |
| <code>S</code>      | penalty matrix.                                       |
| <code>off</code>    | vector of offsets.                                    |
| <code>gamma</code>  | parameter for increasing model smoothness in fitting. |

## Value

A list containing:

- `R`: unpivoted Choleski of estimated expected hessian of log-likelihood.
- `Vb`: the Bayesian covariance matrix of the model parameters.
- `Ve`: "frequentist" alternative to `Vb`.
- `Vc`: corrected covariance matrix.
- `F`: matrix of effective degrees of freedom (EDF).
- `edf`: `diag(F)`.
- `edf2`: `diag(2F-FF)`.

gam.mh

*Simple posterior simulation with gam fits***Description**

GAM coefficients can be simulated directly from the Gaussian approximation to the posterior for the coefficients, or using a simple Metropolis Hastings sampler. See also [ginla](#).

**Usage**

```
gam.mh(b, ns=10000, burn=1000, t.df=40, rw.scale=.25, thin=1)
```

**Arguments**

|          |                                                                                                                                                  |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| b        | a fitted model object from <a href="#">gam</a> . <a href="#">bam</a> fits are not supported.                                                     |
| ns       | the number of samples to generate.                                                                                                               |
| burn     | the length of any initial burn in period to discard (in addition to ns).                                                                         |
| t.df     | degrees of freedom for static multivariate t proposal. Lower for heavier tailed proposals.                                                       |
| rw.scale | Factor by which to scale posterior covariance matrix when generating random walk proposals. Negative or non finite to skip the random walk step. |
| thin     | retain only every thin samples.                                                                                                                  |

**Details**

Posterior simulation is particularly useful for making inferences about non-linear functions of the model coefficients. Simulate random draws from the posterior, compute the function for each draw, and you have a draw from the posterior for the function. In many cases the Gaussian approximation to the posterior of the model coefficients is accurate, and samples generated from it can be treated as samples from the posterior for the coefficients. See example code below. This approach is computationally very efficient.

In other cases the Gaussian approximation can become poor. A typical example is in a spatial model with a log or logit link when there is a large area of observations containing only zeroes. In this case the linear predictor is poorly identified and the Gaussian approximation can become useless (an example is provided below). In that case it can sometimes be useful to simulate from the posterior using a Metropolis Hastings sampler. A simple approach alternates fixed proposals, based on the Gaussian approximation to the posterior, with random walk proposals, based on a shrunk version of the approximate posterior covariance matrix. `gam.mh` implements this. The fixed proposal often promotes rapid mixing, while the random walk component ensures that the chain does not become stuck in regions for which the fixed Gaussian proposal density is much lower than the posterior density.

The function reports the acceptance rate of the two types of step. If the random walk acceptance probability is higher than a quarter then `rw.step` should probably be increased. Similarly if the acceptance rate is too low, it should be decreased. The random walk steps can be turned off altogether (see above), but it is important to check the chains for stuck sections if this is done.

**Value**

A list containing the retained simulated coefficients in matrix `bs` and two entries for the acceptance probabilities.

gam.models

*Specifying generalized additive models*

## Description

This page is intended to provide some more information on how to specify GAMs. A GAM is a GLM in which the linear predictor depends, in part, on a sum of smooth functions of predictors and (possibly) linear functionals of smooth functions of (possibly dummy) predictors.

Specifically let  $y_i$  denote an independent random variable with mean  $\mu_i$  and an exponential family distribution, or failing that a known mean variance relationship suitable for use of quasi-likelihood methods. Then the linear predictor of a GAM has a structure something like

$$g(\mu_i) = \mathbf{X}_i\beta + f_1(x_{1i}, x_{2i}) + f_2(x_{3i}) + L_i f_3(x_4) + \dots$$

where  $g$  is a known smooth monotonic ‘link’ function,  $\mathbf{X}_i\beta$  is the parametric part of the linear predictor, the  $x_j$  are predictor variables, the  $f_j$  are smooth functions and  $L_i$  is some linear functional of  $f_3$ . There may of course be multiple linear functional terms, or none.

The key idea here is that the dependence of the response on the predictors can be represented as a parametric sub-model plus the sum of some (functionals of) smooth functions of one or more of the predictor variables. Thus the model is quite flexible relative to strictly parametric linear or generalized linear models, but still has much more structure than the completely general model that says that the response is just some smooth function of all the covariates.

Note one important point. In order for the model to be identifiable the smooth functions usually have to be constrained to have zero mean (usually taken over the set of covariate values). The constraint is needed if the term involving the smooth includes a constant function in its span. `gam` always applies such constraints unless there is a `by` variable present, in which case an assessment is made of whether the constraint is needed or not (see below).

The following sections discuss specifying model structures for `gam`. Specification of the distribution and link function is done using the `family` argument to `gam` and works in the same way as for `glm`. This page therefore concentrates on the model formula for `gam`.

## Models with simple smooth terms

Consider the example model.

$$g(\mu_i) = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + f_1(x_{3i}) + f_2(x_{4i}, x_{5i})$$

where the response variables  $y_i$  has expectation  $\mu_i$  and  $g$  is a link function.

The gam formula for this would be

`y ~ x1 + x2 + s(x3) + s(x4, x5).`

This would use the default basis for the smooths (a thin plate regression spline basis for each), with automatic selection of the effective degrees of freedom for both smooths. The dimension of the smoothing basis is given a default value as well (the dimension of the basis sets an upper limit on the maximum possible degrees of freedom for the basis - the limit is typically one less than basis dimension). Full details of how to control smooths are given in [s](#) and [te](#), and further discussion of basis dimension choice can be found in [choose.k](#). For the moment suppose that we would like to change the basis of the first smooth to a cubic regression spline basis with a dimension of 20, while fixing the second term at 25 degrees of freedom. The appropriate formula would be:

`y ~ x1 + x2 + s(x3, bs="cr", k=20) + s(x4, x5, k=26, fx=TRUE).`

The above assumes that  $x_4$  and  $x_5$  are naturally on similar scales (e.g. they might be co-ordinates), so that isotropic smoothing is appropriate. If this assumption is false then tensor product smoothing might be better (see [te](#)).

`y ~ x1 + x2 + s(x3) + te(x4, x5)`

would generate a tensor product smooth of  $x_4$  and  $x_5$ . By default this smooth would have basis dimension 25 and use cubic regression spline marginals. Varying the defaults is easy. For example

`y ~ x1 + x2 + s(x3) + te(x4, x5, bs=c("cr", "ps"), k=c(6, 7))`

specifies that the tensor product should use a rank 6 cubic regression spline marginal and a rank 7 P-spline marginal to create a smooth with basis dimension 42.

## Nested terms/functional ANOVA

Sometimes it is interesting to specify smooth models with a main effects + interaction structure such as

$$E(y_i) = f_1(x_i) + f_2(z_i) + f_3(x_i, z_i)$$

or

$$E(y_i) = f_1(x_i) + f_2(z_i) + f_3(v_i) + f_4(x_i, z_i) + f_5(z_i, v_i) + f_6(z_i, v_i) + f_7(x_i, z_i, v_i)$$

for example. Such models should be set up using [ti](#) terms in the model formula. For example:

`y ~ ti(x) + ti(z) + ti(x, z), or`

`y ~ ti(x) + ti(z) + ti(v) + ti(x, z) + ti(x, v) + ti(z, v) + ti(x, z, v).`

The [ti](#) terms produce interactions with the component main effects excluded appropriately. (There is in fact no need to use [ti](#) terms for the main effects here, [s](#) terms could also be used.)

gam allows nesting (or ‘overlap’) of [te](#) and [s](#) smooths, and automatically generates side conditions to make such models identifiable, but the resulting models are much less stable and interpretable than those constructed using [ti](#) terms.

## ‘by’ variables

by variables are the means for constructing ‘varying-coefficient models’ (geographic regression models) and for letting smooths ‘interact’ with factors or parametric terms. They are also the key to specifying general linear functionals of smooths.

The [s](#) and [te](#) terms used to specify smooths accept an argument `by`, which is a numeric or factor variable of the same dimension as the covariates of the smooth. If a `by` variable is numeric, then its  $i^{th}$  element multiplies the  $i^{th}$  row of the model matrix corresponding to the smooth term concerned.

Factor smooth interactions (see also [factor.smooth.interaction](#)). If a by variable is a [factor](#) then it generates an indicator vector for each level of the factor, unless it is an [ordered](#) factor. In the non-ordered case, the model matrix for the smooth term is then replicated for each factor level, and each copy has its rows multiplied by the corresponding rows of its indicator variable. The smoothness penalties are also duplicated for each factor level. In short a different smooth is generated for each factor level (the `id` argument to [s](#) and [te](#) can be used to force all such smooths to have the same smoothing parameter). [ordered](#) by variables are handled in the same way, except that no smooth is generated for the first level of the ordered factor (see `b3` example below). This is useful for setting up identifiable models when the same smooth occurs more than once in a model, with different factor by variables.

As an example, consider the model

$$E(y_i) = \beta_0 + f(x_i)z_i$$

where  $f$  is a smooth function, and  $z_i$  is a numeric variable. The appropriate formula is:

`y ~ s(x, by=z)`

- the `by` argument ensures that the smooth function gets multiplied by covariate  $z$ . Note that when using factor by variables, centering constraints are applied to the smooths, which usually means that the `by` variable should be included as a parametric term, as well.

The example code below also illustrates the use of factor by variables.

by variables may be supplied as numeric matrices as part of specifying general linear functional terms.

If a by variable is present and numeric (rather than a factor) then the corresponding smooth is only subjected to an identifiability constraint if (i) the by variable is a constant vector, or, (ii) for a matrix by variable, `L`, if `L%%rep(1, ncol(L))` is constant or (iii) if a user defined smooth constructor supplies an identifiability constraint explicitly, and that constraint has an attribute `"always.apply"`.

### Linking smooths with 'id'

It is sometimes desirable to insist that different smooth terms have the same degree of smoothness. This can be done by using the `id` argument to [s](#) or [te](#) terms. Smooths which share an `id` will have the same smoothing parameter. Really this only makes sense if the smooths use the same basis functions, and the default behaviour is to force this to happen: all smooths sharing an `id` have the same basis functions as the first smooth occurring with that `id`. Note that if you want exactly the same function for each smooth, then this is best achieved by making use of the summation convention covered under 'linear functional terms'.

As an example suppose that  $E(y_i) \equiv \mu_i$  and

$$g(\mu_i) = f_1(x_{1i}) + f_2(x_{2i}, x_{3i}) + f_3(x_{4i})$$

but that  $f_1$  and  $f_3$  should have the same smoothing parameters (and  $x_2$  and  $x_3$  are on different scales). Then the `gam` formula

`y ~ s(x1, id=1) + te(x_2, x3) + s(x4, id=1)`

would achieve the desired result. `id` can be numbers or character strings. Giving an `id` to a term with a factor by variable causes the smooths at each level of the factor to have the same smoothing parameter.

Smooth term `ids` are not supported by `gamm`.

### Linear functional terms

General linear functional terms have a long history in the spline literature including in the penalized GLM context (see e.g. Wahba 1990). Such terms encompass varying coefficient models/ geographic

regression, functional GLMs (i.e. GLMs with functional predictors), GLASS models, etc, and allow smoothing with respect to aggregated covariate values, for example.

Such terms are implemented in `mgcv` using a simple ‘summation convention’ for smooth terms: If the covariates of a smooth are supplied as matrices, then summation of the evaluated smooth over the columns of the matrices is implied. Each covariate matrix and any by variable matrix must be of the same dimension. Consider, for example the term

`s(X,Z,by=L)`

where  $X$ ,  $Z$  and  $L$  are  $n \times p$  matrices. Let  $f$  denote the thin plate regression spline specified. The resulting contribution to the  $i^{\text{th}}$  element of the linear predictor is

$$\sum_{j=1}^p L_{ij} f(X_{ij}, Z_{ij})$$

If no  $L$  is supplied then all its elements are taken as 1. In R code terms, let  $F$  denote the  $n \times p$  matrix obtained by evaluating the smooth at the values in  $X$  and  $Z$ . Then the contribution of the term to the linear predictor is `rowSums(L*F)` (note that it’s element by element multiplication here!).

The summation convention applies to te terms as well as s terms. More details and examples are provided in [linear.functional.terms](#).

## Random effects

Random effects can be added to gam models using `s(...,bs="re")` terms (see [smooth.construct.re.smooth.spec](#)), or the `paraPen` argument to `gam` covered below. See [gam.vcomp](#), [random.effects](#) and [smooth.construct.re.smooth.spec](#) for further details. An alternative is to use the approach of `gamm`.

## Penalizing the parametric terms

In case the ability to add smooth classes, smooth identities, by variables and the summation convention are still not sufficient to implement exactly the penalized GLM that you require, `gam` also allows you to penalize the parametric terms in the model formula. This is mostly useful in allowing one or more matrix terms to be included in the formula, along with a sequence of quadratic penalty matrices for each.

Suppose that you have set up a model matrix  $X$ , and want to penalize the corresponding coefficients,  $\beta$  with two penalties  $\beta^T S_1 \beta$  and  $\beta^T S_2 \beta$ . Then something like the following would be appropriate: `gam(y ~ X - 1, paraPen=list(X=list(S1,S2)))`

The `paraPen` argument should be a list with elements having names corresponding to the terms being penalized. Each element of `paraPen` is itself a list, with optional elements `L`, `rank` and `sp`: all other elements must be penalty matrices. If present, `rank` is a vector giving the rank of each penalty matrix (if absent this is determined numerically). `L` is a matrix that maps underlying log smoothing parameters to the log smoothing parameters that actually multiply the individual quadratic penalties: taken as the identity if not supplied. `sp` is a vector of (underlying) smoothing parameter values: positive values are taken as fixed, negative to signal that the smoothing parameter should be estimated. Taken as all negative if not supplied.

An obvious application of `paraPen` is to incorporate random effects, and an example of this is provided below. In this case the supplied penalty matrices will be (generalized) inverse covariance matrices for the random effects — i.e. precision matrices. The final estimate of the covariance matrix corresponding to one of these penalties is given by the (generalized) inverse of the penalty matrix multiplied by the estimated scale parameter and divided by the estimated smoothing parameter for the penalty. For example, if you use an identity matrix to penalize some coefficients that are to be viewed as i.i.d. Gaussian random effects, then their estimated variance will be the estimated

scale parameter divided by the estimate of the smoothing parameter, for this penalty. See the ‘rail’ example below.

P-values for penalized parametric terms should be treated with caution. If you must have them, then use the option `freq=TRUE` in `anova.gam` and `summary.gam`, which will tend to give reasonable results for random effects implemented this way, but not for terms with a rank deficient penalty (or penalties with a wide eigen-spectrum).

gam.outer

*Minimize GCV or UBRE score of a GAM using 'outer' iteration*

## Description

Estimation of GAM smoothing parameters is most stable if optimization of the smoothness selection score (GCV, GACV, UBRE/AIC, REML, ML etc) is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine optimizes a smoothness selection score in this way. Basically the score is evaluated for each trial set of smoothing parameters by estimating the GAM for those smoothing parameters. The score is minimized w.r.t. the parameters numerically, using newton (default), bfgs, optim or nlm. Exact (first and second) derivatives of the score can be used by fitting with [gam.fit3](#). This improves efficiency and reliability relative to relying on finite difference derivatives.

Not normally called directly, but rather a service routine for [gam](#).

**Usage**

```
gam.outer(lsp, fscale, family, control, method, optimizer,
 criterion, scale, gamma, G, start=NULL, nei=NULL, ...)
```

**Arguments**

|                        |                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>lsp</code>       | The log smoothing parameters.                                                                                                  |
| <code>fscale</code>    | Typical scale of the GCV or UBRE/AIC score.                                                                                    |
| <code>family</code>    | the model family.                                                                                                              |
| <code>control</code>   | control argument to pass to <a href="#">gam.fit3</a> etc.                                                                      |
| <code>method</code>    | method argument to <a href="#">gam</a> defining the smoothness criterion to use (but depending on whether or not scale known). |
| <code>optimizer</code> | The argument to <a href="#">gam</a> defining the numerical optimization method to use.                                         |
| <code>criterion</code> | Which smoothness selection criterion to use. One of "UBRE", "GCV", "GACV", "REML" or "P-REML".                                 |
| <code>scale</code>     | Supplied scale parameter. Positive indicates known.                                                                            |
| <code>gamma</code>     | The degree of freedom inflation factor for the GCV/UBRE/AIC score.                                                             |
| <code>G</code>         | List produced by <code>mgcv::gam.setup</code> , containing most of what's needed to actually fit a GAM.                        |
| <code>start</code>     | starting parameter values.                                                                                                     |
| <code>nei</code>       | List specifying neighbourhood structure if NCV used. See <a href="#">gam</a> .                                                 |
| <code>...</code>       | other arguments, typically for passing on to <code>gam.fit3</code> (ultimately).                                               |

| gam.reparam | <i>Finding stable orthogonal re-parameterization of the square root penalty.</i> |
|-------------|----------------------------------------------------------------------------------|

---

## Description

INTERNAL function for finding an orthogonal re-parameterization which avoids "dominant machine zero leakage" between components of the square root penalty.

## Usage

```
gam.reparam(rS, lsp, deriv)
```

## Arguments

|       |                                                                                                                                                                                                                                                           |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rS    | list of the square root penalties: last entry is root of fixed penalty, if fixed.penalty==TRUE (i.e. length(rS)>length(sp)). The assumption here is that rS[[i]] are in a null space of total penalty already; see e.g. totalPenaltySpace and mini.roots. |
| lsp   | vector of log smoothing parameters.                                                                                                                                                                                                                       |
| deriv | if deriv==1 also the first derivative of the log-determinant of the penalty matrix is returned, if deriv>1 also the second derivative is returned.                                                                                                        |

## Value

A list containing

- S: the total penalty matrix similarity transformed for stability.
- rS: the component square roots, transformed in the same way.
- Qs: the orthogonal transformation matrix  $S = t(Qs) \% \% S0 \% \% Qs$ , where  $S0$  is the untransformed total penalty implied by sp and rS on input.
- det: log|S|.
- det1: dlog|S|/dlog(sp) if deriv > 0.
- det2: hessian of log|S| wrt log(sp) if deriv > 1.

gam.scale

*Scale parameter estimation in GAMs***Description**

Scale parameter estimation in [gam](#) depends on the type of family. For extended families then the RE/ML estimate is used. For conventional exponential families, estimated by the default outer iteration, the scale estimator can be controlled using argument `scale.est` in [gam.control](#). The options are "fletcher" (default), "pearson" or "deviance". The Pearson estimator is the (weighted) sum of squares of the pearson residuals, divided by the effective residual degrees of freedom. The Fletcher (2012) estimator is an improved version of the Pearson estimator. The deviance estimator simply substitutes deviance residuals for Pearson residuals.

Usually the Pearson estimator is recommended for GLMs, since it is asymptotically unbiased. However, it can also be unstable at finite sample sizes, if a few Pearson residuals are very large. For example, a very low Poisson mean with a non zero count can give a huge Pearson residual, even though the deviance residual is much more modest. The Fletcher (2012) estimator is designed to reduce these problems.

For performance iteration the Pearson estimator is always used.

[gamm](#) uses the estimate of the scale parameter from the underlying call to `lme`. [bam](#) uses the REML estimator if the method is "fREML". Otherwise the estimator is a Pearson estimator.

gam.selection

*Generalized Additive Model Selection***Description**

This page is intended to provide some more information on how to select GAMs. In particular, it gives a brief overview of smoothness selection, and then discusses how this can be extended to select inclusion/exclusion of terms. Hypothesis testing approaches to the latter problem are also discussed.

### Smoothness selection criteria

Given a model structure specified by a gam model formula, `gam()` attempts to find the appropriate smoothness for each applicable model term using prediction error criteria or likelihood based methods. The prediction error criteria used are Generalized (Approximate) Cross Validation (GCV or GACV) when the scale parameter is unknown or an Un-Biased Risk Estimator (UBRE) when it is known. UBRE is essentially scaled AIC (Generalized case) or Mallows'  $C_p$  (additive model case). GCV and UBRE are covered in Craven and Wahba (1979) and Wahba (1990). Alternatively REML of maximum likelihood (ML) may be used for smoothness selection, by viewing the smooth components as random effects (in this case the variance component for each smooth random effect will be given by the scale parameter divided by the smoothing parameter — for smooths with multiple penalties, there will be multiple variance components). The `method` argument to `gam` selects the smoothness selection criterion.

Automatic smoothness selection is unlikely to be successful with few data, particularly with multiple terms to be selected. In addition GCV and UBRE/AIC score can occasionally display local minima that can trap the minimisation algorithms. GCV/UBRE/AIC scores become constant with changing smoothing parameters at very low or very high smoothing parameters, and on occasion these 'flat' regions can be separated from regions of lower score by a small 'lip'. This seems to be the most common form of local minimum, but is usually avoidable by avoiding extreme smoothing parameters as starting values in optimization, and by avoiding big jumps in smoothing parameters while optimizing. Never the less, if you are suspicious of smoothing parameter estimates, try changing fit method (see `gam` arguments `method` and `optimizer`) and see if the estimates change, or try changing some or all of the smoothing parameters 'manually' (argument `sp` of `gam`, or `sp` arguments to `s` or `te`).

REML and ML are less prone to local minima than the other criteria, and may therefore be preferable.

### Automatic term selection

Unmodified smoothness selection by GCV, AIC, REML etc. will not usually remove a smooth from a model. This is because most smoothing penalties view some space of (non-zero) functions as 'completely smooth' and once a term is penalized heavily enough that it is in this space, further penalization does not change it.

However it is straightforward to modify smooths so that under heavy penalization they are penalized to the zero function and thereby 'selected out' of the model. There are two approaches.

The first approach is to modify the smoothing penalty with an additional shrinkage term. Smooth classes `cs.smooth` and `tps.smooth` (specified by "`cs`" and "`ts`" respectively) have smoothness penalties which include a small shrinkage component, so that for large enough smoothing parameters the smooth becomes identically zero. This allows automatic smoothing parameter selection methods to effectively remove the term from the model altogether. The shrinkage component of the penalty is set at a level that usually makes negligible contribution to the penalization of the model, only becoming effective when the term is effectively 'completely smooth' according to the conventional penalty.

The second approach leaves the original smoothing penalty unchanged, but constructs an additional penalty for each smooth, which penalizes only functions in the null space of the original penalty (the 'completely smooth' functions). Hence, if all the smoothing parameters for a term tend to infinity, the term will be selected out of the model. This latter approach is more expensive computationally, but has the advantage that it can be applied automatically to any smooth term. The `select` argument to `gam` turns on this method.

In fact, as implemented, both approaches operate by eigen-decomposing the original penalty matrix. A new penalty is created on the null space: it is the matrix with the same eigenvectors as

the original penalty, but with the originally positive eigenvalues set to zero, and the originally zero eigenvalues set to something positive. The first approach just adds a multiple of this penalty to the original penalty, where the multiple is chosen so that the new penalty can not dominate the original. The second approach treats the new penalty as an extra penalty, with its own smoothing parameter.

Of course, as with all model selection methods, some care must be taken to ensure that the automatic selection is sensible, and a decision about the effective degrees of freedom at which to declare a term ‘negligible’ has to be made.

### Interactive term selection

In general the most logically consistent method to use for deciding which terms to include in the model is to compare GCV/UBRE/ML scores for models with and without the term (REML scores should not be used to compare models with different fixed effects structures). When UBRE is the smoothness selection method this will give the same result as comparing by AIC (the AIC in this case uses the model EDF in place of the usual model DF). Similarly, comparison via GCV score and via AIC seldom yields different answers. Note that the negative binomial with estimated theta parameter is a special case: the GCV score is not informative, because of the theta estimation scheme used. More generally the score for the model with a smooth term can be compared to the score for the model with the smooth term replaced by appropriate parametric terms. Candidates for replacement by parametric terms are smooth terms with estimated degrees of freedom close to their minimum possible.

Candidates for removal can also be identified by reference to the approximate p-values provided by `summary.gam`, and by looking at the extent to which the confidence band for an estimated term includes the zero function. It is perfectly possible to perform backwards selection using p-values in the usual way: that is by sequentially dropping the single term with the highest non-significant p-value from the model and re-fitting, until all terms are significant. This suffers from the same problems as stepwise procedures for any GLM/LM, with the additional caveat that the p-values are only approximate. If adopting this approach, it is probably best to use ML smoothness selection.

Note that GCV and UBRE are not appropriate for comparing models using different families: in that case AIC should be used.

### Caveats/platitudes

Formal model selection methods are only appropriate for selecting between reasonable models. If formal model selection is attempted starting from a model that simply doesn’t fit the data, then it is unlikely to provide meaningful results.

The more thought is given to appropriate model structure up front, the more successful model selection is likely to be. Simply starting with a hugely flexible model with ‘everything in’ and hoping that automatic selection will find the right structure is not often successful.

gam.side

*Identifiability side conditions for a GAM*

---

## Description

GAM formulae with repeated variables may only correspond to identifiable models given some side conditions. This routine works out appropriate side conditions, based on zeroing redundant parameters. It is called from `mgcv:::gam.setup` and is not intended to be called by users.

The method identifies nested and repeated variables by their names, but numerically evaluates which constraints need to be imposed. Constraints are always applied to smooths of more variables in preference to smooths of fewer variables. The numerical approach allows appropriate constraints to be applied to models constructed using any smooths, including user defined smooths.

## Usage

```
gam.side(sm,Xp,tol=.Machine$double.eps^.5,with.pen=TRUE)
```

## Arguments

|          |                                                                                                              |
|----------|--------------------------------------------------------------------------------------------------------------|
| sm       | A list of smooth objects as returned by <a href="#">smooth.construct</a> .                                   |
| Xp       | The model matrix for the strictly parametric model components.                                               |
| tol      | The tolerance to use when assessing linear dependence of smooths.                                            |
| with.pen | Should the computation of dependence consider the penalties or not. Doing so will lead to fewer constraints. |

## Details

Models such as  $y \sim s(x) + s(z) + s(x, z)$  can be estimated by [gam](#), but require identifiability constraints to be applied, to make them identifiable. This routine does this, effectively setting redundant parameters to zero. When the redundancy is between smooths of lower and higher numbers of variables, the constraint is always applied to the smooth of the higher number of variables.

Dependent smooths are identified symbolically, but which constraints are needed to ensure identifiability of these smooths is determined numerically, using [fixDependence](#). This makes the routine rather general, and not dependent on any particular basis.

Xp is used to check whether there is a constant term in the model (or columns that can be linearly combined to give a constant). This is because centred smooths can appear independent, when they would be dependent if there is a constant in the model, so dependence testing needs to take account of this.

## Value

A list of smooths, with model matrices and penalty matrices adjusted to automatically impose the required constraints. Any smooth that has been modified will have an attribute "del.index", listing the columns of its model matrix that were deleted. This index is used in the creation of prediction matrices for the term.

## WARNINGS

Much better statistical stability will be obtained by using models like  $y \sim s(x) + s(z) + ti(x, z)$  or  $y \sim ti(x) + ti(z) + ti(x, z)$  rather than  $y \sim s(x) + s(z) + s(x, z)$ , since the former are designed not to require further constraint.

The first two examples here illustrate models that cause
gam.side to impose constraints, but both are a bad way
of estimating such models. The 3rd example is the right
way...
set.seed(7)
require(mgcv)
dat <- gamSim(n=400, scale=2) ## simulate data
estimate model with redundant smooth interaction (bad idea).
b <- gam(y ~ s(x0) + s(x1) + s(x0, x1) + s(x2), data=dat)
plot(b, pages=1)

Simulate data with real interaction...
dat <- gamSim(2, n=500, scale=.1)
old.par <- par(mfrow=c(2, 2))

a fully nested tensor product example (bad idea)
b <- gam(y ~ s(x, bs="cr", k=6) + s(z, bs="cr", k=6) + te(x, z, k=6),
 data=dat$data)
```

```

plot(b)

old.par<-par(mfrow=c(2,2))
A fully nested tensor product example, done properly,
so that gam.side is not needed to ensure identifiability.
ti terms are designed to produce interaction smooths
suitable for adding to main effects (we could also have
used s(x) and s(z) without a problem, but not s(z,x)
or te(z,x)).
b <- gam(y ~ ti(x,k=6) + ti(z,k=6) + ti(x,z,k=6),
 data=dat$data)
plot(b)

par(old.par)
rm(dat)

```

gam.vcomp

*Report gam smoothness estimates as variance components*

## Description

GAMs can be viewed as mixed models, where the smoothing parameters are related to variance components. This routine extracts the estimated variance components associated with each smooth term, and if possible returns confidence intervals on the standard deviation scale.

## Usage

```

gam.vcomp(x,rescale=TRUE,conf.lev=.95)

S3 method for class 'gam.vcomp'
print(x,...)

```

## Arguments

|          |                                                                                                                                                                                                                    |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x        | a fitted model object of class gam as produced by gam(), or an object of class gam.vcomp for the print method.                                                                                                     |
| rescale  | the penalty matrices for smooths are rescaled before fitting, for numerical stability reasons, if TRUE this rescaling is reversed, so that the variance components are on the original scale.                      |
| conf.lev | when the smoothing parameters are estimated by REML or ML, then confidence intervals for the variance components can be obtained from large sample likelihood results. This gives the confidence level to work at. |
| ...      | other arguments.                                                                                                                                                                                                   |

## Details

The (pseudo) inverse of the penalty matrix penalizing a term is proportional to the covariance matrix of the term's coefficients, when these are viewed as random. For single penalty smooths, it is possible to compute the variance component for the smooth (which multiplies the inverse penalty matrix to obtain the covariance matrix of the smooth's coefficients). This variance component is given by the scale parameter divided by the smoothing parameter.

This routine computes such variance components, for gam models, and associated confidence intervals, if smoothing parameter estimation was likelihood based. Note that variance components are also returned for tensor product smooths, but that their interpretation is not so straightforward.

The routine is particularly useful for model fitted by [gam](#) in which random effects have been incorporated.

### Value

Either a vector of variance components for each smooth term (as standard deviations), or a list. A list will be returned if the smoothness selection method used was REML or ML, or where a model has more smoothing parameters than actually estimated.

If a list, it will contain some or all of the elements described depending on the method of smoothness selection used, and whether some smoothing parameters were not estimated.

Depending on the smoothness selection method, element `vc` may contain a matrix or a vector. If REML or ML smoothness selection was used, `vc` will be a matrix whose first column gives standard deviations for each term, while the subsequent columns give lower and upper confidence bounds, on the same scale. For models fitted with other smoothness selection methods, component `vc` will be a vector of standard deviations.

The `all` element is a vector of variance components for all the smoothing parameters (estimated + fixed or replicated).

Additionally, for REML or ML smoothness selection, the numerical rank of the covariance matrix and the Hessian matrix are returned as elements `rank` and `rank.hess` respectively.

### Examples

```
set.seed(3)
require(mgcv)
simulate some data, consisting of a smooth truth + random effects

dat <- gamSim(1,n=400,dist="normal",scale=2)
a <- factor(sample(1:10,400,replace=TRUE))
b <- factor(sample(1:7,400,replace=TRUE))
Xa <- model.matrix(~a-1) ## random main effects
Xb <- model.matrix(~b-1)
Xab <- model.matrix(~a:b-1) ## random interaction
dat$y <- dat$y + Xa%*%rnorm(10)*.5 +
 Xb%*%rnorm(7)*.3 + Xab%*%rnorm(70)*.7
dat$a <- a;dat$b <- b
```

```
Fit the model using "re" terms, and smoother linkage

mod <- gam(y~s(a,bs="re")+s(b,bs="re")+s(a,b,bs="re")+s(x0,id=1)+s(x1,id=1)+
 s(x2,k=15)+s(x3),data=dat,method="ML")

gam.vcomp(mod)
```

gam2objective

*Objective functions for GAM smoothing parameter estimation*

## Description

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC or GCV score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters. These functions evaluate the GCV/UBRE/AIC score of a GAM model, given smoothing parameters, in a manner suitable for use by [optim](#) or [nlm](#). Not normally called directly, but rather service routines for [gam.outer](#).

## Usage

```
gam2objective(lsp,args,...)
gam2derivative(lsp,args,...)
```

## Arguments

|                   |                                                               |
|-------------------|---------------------------------------------------------------|
| <code>lsp</code>  | The log smoothing parameters.                                 |
| <code>args</code> | List of arguments required to call <a href="#">gam.fit3</a> . |
| <code>...</code>  | Other arguments for passing to <a href="#">gam.fit3</a> .     |

## Details

`gam2objective` and `gam2derivative` are functions suitable for calling by [optim](#), to evaluate the GCV/UBRE/AIC score and its derivatives w.r.t. log smoothing parameters.

`gam4objective` is an equivalent to `gam2objective`, suitable for optimization by [nlm](#) - derivatives of the GCV/UBRE/AIC function are calculated and returned as attributes.

The basic idea of optimizing smoothing parameters ‘outer’ to the P-IRLS loop was first proposed in O’Sullivan et al. (1986).

gamlss.etamu

---

*Transform derivatives wrt mu to derivatives wrt linear predictor*

---

**Description**

Mainly intended for internal use in specifying location scale models. Let  $g(\mu) = lp$ , where  $lp$  is the linear predictor, and  $g$  is the link function. Assume that we have calculated the derivatives of the log-likelihood wrt  $\mu$ . This function uses the chain rule to calculate the derivatives of the log-likelihood wrt  $lp$ . See [trind.generator](#) for array packing conventions.

**Usage**

```
gamlss.etamu(l1, l2, l3 = NULL, l4 = NULL, ig1, g2, g3 = NULL,
 g4 = NULL, i2, i3 = NULL, i4 = NULL, deriv = 0)
```

**Arguments**

|                    |                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>l1</code>    | array of 1st order derivatives of log-likelihood wrt $\mu$ .                                                                                                                                                          |
| <code>l2</code>    | array of 2nd order derivatives of log-likelihood wrt $\mu$ .                                                                                                                                                          |
| <code>l3</code>    | array of 3rd order derivatives of log-likelihood wrt $\mu$ .                                                                                                                                                          |
| <code>l4</code>    | array of 4th order derivatives of log-likelihood wrt $\mu$ .                                                                                                                                                          |
| <code>ig1</code>   | reciprocal of the first derivative of the link function wrt the linear predictor.                                                                                                                                     |
| <code>g2</code>    | array containing the 2nd order derivative of the link function wrt the linear predictor.                                                                                                                              |
| <code>g3</code>    | array containing the 3rd order derivative of the link function wrt the linear predictor.                                                                                                                              |
| <code>g4</code>    | array containing the 4th order derivative of the link function wrt the linear predictor.                                                                                                                              |
| <code>i2</code>    | two-dimensional index array, such that <code>l2[, i2[i, j]]</code> contains the partial w.r.t. params indexed by $i, j$ with no restriction on the index values (except that they are in $1, \dots, ncol(l1)$ ).      |
| <code>i3</code>    | third-dimensional index array, such that <code>l3[, i3[i, j, k]]</code> contains the partial w.r.t. params indexed by $i, j, k$ .                                                                                     |
| <code>i4</code>    | third-dimensional index array, such that <code>l4[, i4[i, j, k, l]]</code> contains the partial w.r.t. params indexed by $i, j, k, l$ .                                                                               |
| <code>deriv</code> | if <code>deriv==0</code> only first and second order derivatives will be calculated. If <code>deriv==1</code> the function goes up to 3rd order, and if <code>deriv==2</code> it provides also 4th order derivatives. |

**Value**

A list where the arrays `l1`, `l2`, `l3`, `l4` contain the derivatives (up to order four) of the log-likelihood wrt the linear predictor.

gamlss.gH

*Calculating derivatives of log-likelihood wrt regression coefficients*

---

**Description**

Mainly intended for internal use with location scale model families. Given the derivatives of the log-likelihood wrt the linear predictor, this function obtains the derivatives and Hessian wrt the regression coefficients and derivatives of the Hessian w.r.t. the smoothing parameters. For input derivative array packing conventions see [trind.generator](#).

**Usage**

```
gamlss.gH(X, jj, l1, l2, i2, l3 = 0, i3 = 0, l4 = 0, i4 = 0, d1b = 0,
 d2b = 0, deriv = 0, fh = NULL, D = NULL, sandwich=FALSE)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X     | matrix containing the model matrices of all the linear predictors.                                                                                                                                                                                                                                                                |
| jj    | list of index vectors such that <code>X[, jj[[i]]]</code> is the model matrix of the i-th linear predictor.                                                                                                                                                                                                                       |
| l1    | array of 1st order derivatives of each element of the log-likelihood wrt each parameter.                                                                                                                                                                                                                                          |
| l2    | array of 2nd order derivatives of each element of the log-likelihood wrt each parameter.                                                                                                                                                                                                                                          |
| i2    | two-dimensional index array, such that <code>l2[, i2[i, j]]</code> contains the partial w.r.t. params indexed by i,j with no restriction on the index values (except that they are in 1,...,ncol(l1)).                                                                                                                            |
| l3    | array of 3rd order derivatives of each element of the log-likelihood wrt each parameter.                                                                                                                                                                                                                                          |
| i3    | third-dimensional index array, such that <code>l3[, i3[i, j, k]]</code> contains the partial w.r.t. params indexed by i,j,k.                                                                                                                                                                                                      |
| l4    | array of 4th order derivatives of each element of the log-likelihood wrt each parameter.                                                                                                                                                                                                                                          |
| i4    | third-dimensional index array, such that <code>l4[, i4[i, j, k, l]]</code> contains the partial w.r.t. params indexed by i,j,k,l.                                                                                                                                                                                                 |
| d1b   | first derivatives of the regression coefficients wrt the smoothing parameters.                                                                                                                                                                                                                                                    |
| d2b   | second derivatives of the regression coefficients wrt the smoothing parameters.                                                                                                                                                                                                                                                   |
| deriv | if <code>deriv==0</code> only first and second order derivatives will be calculated. If <code>deriv==1</code> the function return also the diagonal of the first derivative of the Hessian, if <code>deriv==2</code> it return the full 3rd order derivative and if <code>deriv==3</code> it provides also 4th order derivatives. |

|          |                                                                                       |
|----------|---------------------------------------------------------------------------------------|
| fh       | eigen-decomposition or Cholesky factor of the penalized Hessian.                      |
| D        | diagonal matrix, used to provide some scaling.                                        |
| sandwich | set to TRUE to return sandwich estimator 'filling', as opposed to the Hessian, in 12. |

### Value

A list containing lb - the grad vector w.r.t. coefs; lbb - the Hessian matrix w.r.t. coefs; d1H - either a list of the derivatives of the Hessian w.r.t. the smoothing parameters, or a single matrix whose columns are the leading diagonals of these dervative matrices; trHid2H - the trace of the inverse Hessian multiplied by the second derivative of the Hessian w.r.t. all combinations of smoothing parameters.

gamm

*Generalized Additive Mixed Models*

---

### Description

Fits the specified generalized additive mixed model (GAMM) to data, by a call to lme in the normal errors identity link case, or by a call to gammPQL (a modification of glmmPQL from the MASS library) otherwise. In the latter case estimates are only approximately MLEs. The routine is typically slower than gam, and not quite as numerically robust.

To use lme4 in place of nlme as the underlying fitting engine, see gamm4 from package gamm4.

Smooths are specified as in a call to [gam](#) as part of the fixed effects model formula, but the wiggly components of the smooth are treated as random effects. The random effects structures and correlation structures available for lme are used to specify other random effects and correlations.

It is assumed that the random effects and correlation structures are employed primarily to model residual correlation in the data and that the prime interest is in inference about the terms in the fixed effects model formula including the smooths. For this reason the routine calculates a posterior covariance matrix for the coefficients of all the terms in the fixed effects formula, including the smooths.

To use this function effectively it helps to be quite familiar with the use of [gam](#) and [lme](#).

### Usage

```
gamm(formula, random=NULL, correlation=NULL, family=gaussian(),
data=list(), weights=NULL, subset=NULL, na.action, knots=NULL,
control=list(niterEM=0, optimMethod="L-BFGS-B", returnObject=TRUE),
niterPQL=20, verbosePQL=TRUE, method="ML", drop.unused.levels=TRUE,
mustart=NULL, etastart=NULL,...)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula            | A GAM formula (see also <a href="#">formula.gam</a> and <a href="#">gam.models</a> ). This is like the formula for a <code>glm</code> except that smooth terms ( <code>s</code> , <code>te</code> etc.) can be added to the right hand side of the formula. Note that <code>ids</code> for smooths and fixed smoothing parameters are not supported. Any offset should be specified in the formula.                                                                                                                                                                                                                                                                                      |
| random             | The (optional) random effects structure as specified in a call to <a href="#">lme</a> : only the <code>list</code> form is allowed, to facilitate manipulation of the random effects structure within <code>gamm</code> in order to deal with smooth terms. See example below.                                                                                                                                                                                                                                                                                                                                                                                                           |
| correlation        | An optional <code>corStruct</code> object (see <a href="#">corClasses</a> ) as used to define correlation structures in <a href="#">lme</a> . Any grouping factors in the formula for this object are assumed to be nested within any random effect grouping factors, without the need to make this explicit in the formula (this is slightly different to the behaviour of <code>lme</code> ). This is a GEE approach to correlation in the generalized case. See examples below.                                                                                                                                                                                                       |
| family             | A family as used in a call to <a href="#">glm</a> or <a href="#">gam</a> . The default gaussian with identity link causes <code>gamm</code> to fit by a direct call to <a href="#">lme</a> provided there is no offset term, otherwise <code>gammPQL</code> is used.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| data               | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>gamm</code> is called.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| weights            | In the generalized case, weights with the same meaning as <a href="#">glm</a> weights. An <code>lme</code> type weights argument may only be used in the identity link gaussian case, with no offset (see documentation for <code>lme</code> for details of how to use such an argument).                                                                                                                                                                                                                                                                                                                                                                                                |
| subset             | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| na.action          | a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| knots              | this is an optional list containing user specified knot values to be used for basis construction. Different terms can use different numbers of knots, unless they share a covariate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| control            | A list of fit control parameters for <a href="#">lme</a> to replace the defaults returned by <a href="#">lmeControl</a> . Note the setting for the number of EM iterations used by <code>lme</code> : smooths are set up using custom <code>pdMat</code> classes, which are currently not supported by the EM iteration code. If you supply a list of control values, it is advisable to include <code>niterEM=0</code> , as well, and only increase from 0 if you want to perturb the starting values used in model fitting (usually to worse values!). The <code>optimMethod</code> option is only used if your version of R does not have the <code>nlminb</code> optimizer function. |
| niterPQL           | Maximum number of PQL iterations (if any).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| verbosePQL         | Should PQL report its progress as it goes along?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| method             | Which of "ML" or "REML" to use in the Gaussian additive mixed model case when <code>lme</code> is called directly. Ignored in the generalized case (or if the model has an offset), in which case <code>gammPQL</code> is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| drop.unused.levels | by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                       |                                                                                                 |
|-----------------------|-------------------------------------------------------------------------------------------------|
| <code>mustart</code>  | starting values for mean if PQL used.                                                           |
| <code>etastart</code> | starting values for linear predictor if PQL used (over-rides <code>mustart</code> if supplied). |
| <code>...</code>      | further arguments for passing on e.g. to <code>lme</code>                                       |

## Details

The Bayesian model of spline smoothing introduced by Wahba (1983) and Silverman (1985) opens up the possibility of estimating the degree of smoothness of terms in a generalized additive model as variances of the wiggly components of the smooth terms treated as random effects. Several authors have recognised this (see Wang 1998; Ruppert, Wand and Carroll, 2003) and in the normal errors, identity link case estimation can be performed using general linear mixed effects modelling software such as `lme`. In the generalized case only approximate inference is so far available, for example using the Penalized Quasi-Likelihood approach of Breslow and Clayton (1993) as implemented in `glmmPQL` by Venables and Ripley (2002). One advantage of this approach is that it allows correlated errors to be dealt with via random effects or the correlation structures available in the `nlme` library (using correlation structures beyond the strictly additive case amounts to using a GEE approach to fitting).

Some details of how GAMs are represented as mixed models and estimated using `lme` or `gammPQL` in `gamm` can be found in Wood (2004, 2006a,b). In addition `gamm` obtains a posterior covariance matrix for the parameters of all the fixed effects and the smooth terms. The approach is similar to that described in Lin & Zhang (1999) - the covariance matrix of the data (or pseudodata in the generalized case) implied by the weights, correlation and random effects structure is obtained, based on the estimates of the parameters of these terms and this is used to obtain the posterior covariance matrix of the fixed and smooth effects.

The bases used to represent smooth terms are the same as those used in `gam`, although adaptive smoothing bases are not available. Prediction from the returned `gam` object is straightforward using `predict.gam`, but this will set the random effects to zero. If you want to predict with random effects set to their predicted values then you can adapt the prediction code given in the examples below.

In the event of `lme` convergence failures, consider modifying `options(mgcv.vc.logrange)`: reducing it helps to remove indefiniteness in the likelihood, if that is the problem, but too large a reduction can force over or undersmoothing. See [notExp2](#) for more information on this option. Failing that, you can try increasing the `niterEM` option in `control`: this will perturb the starting values used in fitting, but usually to values with lower likelihood! Note that this version of `gamm` works best with R 2.2.0 or above and `nlme`, 3.1-62 and above, since these use an improved optimizer.

## Value

Returns a list with two items:

|                  |                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gam</code> | an object of class <code>gam</code> , less information relating to GCV/UBRE model selection. At present this contains enough information to use <code>predict</code> , <code>summary</code> and <code>print</code> methods and <code>vis.gam</code> , but not to use e.g. the <code>anova</code> method function to compare models. This is based on the working model when using <code>gammPQL</code> . |
| <code>lme</code> | the fitted model object returned by <code>lme</code> or <code>gammPQL</code> . Note that the model formulae and grouping structures may appear to be rather bizarre, because of the manner in which the GAMM is split up and the calls to <code>lme</code> and <code>gammPQL</code> are constructed.                                                                                                     |

## WARNINGS

`gamm` has a somewhat different argument list to `gam`, `gam` arguments such as `gamma` supplied to `gamm` will just be ignored.

`gamm` performs poorly with binary data, since it uses PQL. It is better to use `gam` with `s(..., bs="re")` terms, or `gamm4`.

`gamm` assumes that you know what you are doing! For example, unlike `glmmPQL` from MASS it will return the complete `lme` object from the working model at convergence of the PQL iteration, including the ‘log likelihood’, even though this is not the likelihood of the fitted GAMM.

The routine will be very slow and memory intensive if correlation structures are used for the very large groups of data. e.g. attempting to run the spatial example in the examples section with many 1000’s of data is definitely not recommended: often the correlations should only apply within clusters that can be defined by a grouping factor, and provided these clusters do not get too huge then fitting is usually possible.

Models must contain at least one random effect: either a smooth with non-zero smoothing parameter, or a random effect specified in argument `random`.

`gamm` is not as numerically stable as `gam`: an `lme` call will occasionally fail. See details section for suggestions, or try the ‘`gamm4`’ package.

`gamm` is usually much slower than `gam`, and on some platforms you may need to increase the memory available to R in order to use it with large data sets (see [memory.limit](#)).

Note that the weights returned in the fitted GAM object are dummy, and not those used by the PQL iteration: this makes partial residual plots look odd.

Note that the `gam` object part of the returned object is not complete in the sense of having all the elements defined in [gamObject](#) and does not inherit from `glm`: hence e.g. multi-model anova calls will not work. It is also based on the working model when PQL is used.

The parameterization used for the smoothing parameters in `gamm`, bounds them above and below by an effective infinity and effective zero. See [notExp2](#) for details of how to change this.

Linked smoothing parameters and adaptive smoothing are not supported.

### Examples

```
library(mgcv)
simple examples using gamm as alternative to gam
set.seed(0)
dat <- gamSim(1,n=200,scale=2)
b <- gamm(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
plot(b$gam,pages=1)
summary(b$lme) # details of underlying lme fit
summary(b$gam) # gam style summary of fitted model
anova(b$gam)
gam.check(b$gam) # simple checking plots

b <- gamm(y~te(x0,x1)+s(x2)+s(x3),data=dat)
op <- par(mfrow=c(2,2))
plot(b$gam)
par(op)
rm(dat)

Add a factor to the linear predictor, to be modelled as random
dat <- gamSim(6,n=200,scale=.2,dist="poisson")
b2 <- gamm(y~s(x0)+s(x1)+s(x2),family=poisson,
 data=dat,random=list(fac=~1))
plot(b2$gam,pages=1)
fac <- dat$fac
rm(dat)
vis.gam(b2$gam)

In the generalized case the 'gam' object is based on the working
model used in the PQL fitting. Residuals for this are not
that useful on their own as the following illustrates...

gam.check(b2$gam)

But more useful residuals are easy to produce on a model
by model basis. For example...

fv <- exp(fitted(b2$lme)) ## predicted values (including re)
rsd <- (b2gamy - fv)/sqrt(fv) ## Pearson residuals (Poisson case)
```

```

op <- par(mfrow=c(1,2))
qqnorm(rsd);plot(fv^.5,rsd)
par(op)

now an example with autocorrelated errors....
n <- 200;sig <- 2
x <- 0:(n-1)/(n-1)
f <- 0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10
e <- rnorm(n,0,sig)
for (i in 2:n) e[i] <- 0.6*e[i-1] + e[i]
y <- f + e
op <- par(mfrow=c(2,2))
Fit model with AR1 residuals
b <- gamm(y~s(x,k=20),correlation=corAR1())
plot(b$gam);lines(x,f-mean(f),col=2)
Raw residuals still show correlation, of course...
acf(residuals(b$gam),main="raw residual ACF")
But standardized are now fine...
acf(residuals(b$lme,type="normalized"),main="standardized residual ACF")
compare with model without AR component...
b <- gam(y~s(x,k=20))
plot(b);lines(x,f-mean(f),col=2)

more complicated autocorrelation example - AR errors
only within groups defined by `fac'
e <- rnorm(n,0,sig)
for (i in 2:n) e[i] <- 0.6*e[i-1]*(fac[i-1]==fac[i]) + e[i]
y <- f + e
b <- gamm(y~s(x,k=20),correlation=corAR1(form=~1|fac))
plot(b$gam);lines(x,f-mean(f),col=2)
par(op)

more complex situation with nested random effects and within
group correlation

set.seed(0)
n.g <- 10
n<-n.g*10*4
simulate smooth part...
dat <- gamSim(1,n=n,scale=2)
f <- dat$f
simulate nested random effects....
fa <- as.factor(rep(1:10,rep(4*n.g,10)))
ra <- rep(rnorm(10),rep(4*n.g,10))
fb <- as.factor(rep(rep(1:4,rep(n.g,4)),10))
rb <- rep(rnorm(4),rep(n.g,4))
for (i in 1:9) rb <- c(rb,rep(rnorm(4),rep(n.g,4)))
simulate auto-correlated errors within groups
e<-array(0,0)
for (i in 1:40) {
 eg <- rnorm(n.g, 0, sig)
 for (j in 2:n.g) eg[j] <- eg[j-1]*0.6+ eg[j]
 e<-c(e,eg)
}
dat$y <- f + ra + rb + e
dat$fa <- fa;dat$fb <- fb
fit model

```

```

b <- gamm(y~s(x0,bs="cr")+s(x1,bs="cr")+s(x2,bs="cr")+
 s(x3,bs="cr"),data=dat,random=list(fa=~1,fb=~1),
 correlation=corAR1())
plot(b$gam,pages=1)
summary(b$gam)
vis.gam(b$gam)

Prediction from gam object, optionally adding
in random effects.

Extract random effects and make names more convenient...
refa <- ranef(b$lme,level=5)
rownames(refa) <- substr(rownames(refa),start=9,stop=20)
refb <- ranef(b$lme,level=6)
rownames(refb) <- substr(rownames(refb),start=9,stop=20)

make a prediction, with random effects zero...
p0 <- predict(b$gam,data.frame(x0=.3,x1=.6,x2=.98,x3=.77))

add in effect for fa = "2" and fb="2/4"...
p <- p0 + refa["2",1] + refb["2/4",1]

and a "spatial" example...
library(nlme);set.seed(1);n <- 100
dat <- gamSim(2,n=n,scale=0) ## standard example
attach(dat)
old.par<-par(mfrow=c(2,2))
contour(truth$x,truth$z,truth$f) ## true function
f <- data$f ## true expected response
Now simulate correlated errors...
cstr <- corGaus(.1,form = ~x+z)
cstr <- Initialize(cstr,data.frame(x=data$x,z=data$z))
V <- corMatrix(cstr) ## correlation matrix for data
Cv <- chol(V)
e <- t(Cv) %*% rnorm(n)*0.05 # correlated errors
next add correlated simulated errors to expected values
data$y <- f + e ## ... to produce response
b<- gamm(y~s(x,z,k=50),correlation=corGaus(.1,form=~x+z),
 data=data)
plot(b$gam) # gamm fit accounting for correlation
overfits when correlation ignored....
b1 <- gamm(y~s(x,z,k=50),data=data);plot(b1$gam)
b2 <- gam(y~s(x,z,k=50),data=data);plot(b2)
par(old.par)

```

## Description

The `gammals` family implements gamma location scale additive models in which the log of the mean,  $\mu$ , and the log of the scale parameter,  $\phi$  (see details) can depend on additive smooth predictors. The parameterization is of the usual GLM type where the variance of the response is given by  $\phi\mu^2$ . Useable only with `gam`, the linear predictors are specified via a list of formulae.

**Usage**

```
gammals(link=list("identity","log"),b=-7)
```

**Arguments**

|      |                                                                                                                                |
|------|--------------------------------------------------------------------------------------------------------------------------------|
| link | two item list specifying the link for the mean and the standard deviation. See details for meaning which may not be intuitive. |
| b    | The minimum log scale parameter.                                                                                               |

**Details**

Used with `gam` to fit gamma location - scale models parameterized in terms of the log mean and the log scale parameter (the response variance is the squared mean multiplied by the scale parameter). Note that `identity` links mean that the linear predictors give the log mean and log scale directly. By default the log link for the scale parameter simply forces the log scale parameter to have a lower limit given by argument `b`: if  $\eta$  is the linear predictor for the log scale parameter,  $\phi$ , then  $\log \phi = b + \log(1 + e^{\eta-b})$ .

`gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the log mean on the right hand side. The second is one sided, specifying the linear predictor for the log scale on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the mean (on original, not log, scale), and the second column is the log scale. Predictions using `predict.gam` will also produce 2 column matrices for type `"link"` and `"response"`. The first column is on the original data scale when type=`"response"` and on the log mean scale of the linear predictor when type=`"link"`. The second column when type=`"response"` is again the log scale parameter, but is on the linear predictor when type=`"link"`.

The null deviance reported for this family computed by setting the fitted values to the mean response, but using the model estimated scale.

**Value**

An object inheriting from class `general.family`.

**Examples**

```
library(mgcv)
simulate some data
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x) exp(2 * x)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
f3 <- function(x) 0 * x
n <- 400; set.seed(9)
x0 <- runif(n); x1 <- runif(n);
x2 <- runif(n); x3 <- runif(n);
mu <- exp((f0(x0)+f2(x2))/5)
th <- exp(f1(x1)/2-2)
```

```

y <- rgamma(n, shape=1/th, scale=mu*th)

b1 <- gam(list(y~s(x0)+s(x2), ~s(x1)+s(x3)), family=gammals)
plot(b1, pages=1)
summary(b1)
gam.check(b1)
plot(mu, fitted(b1)[,1]); abline(0,1,col=2)
plot(log(th), fitted(b1)[,2]); abline(0,1,col=2)

```

gamObject

*Fitted gam object*

## Description

A fitted GAM object returned by function `gam` and of class `"gam"` inheriting from classes `"glm"` and `"lm"`. Method functions `anova`, `logLik`, `influence`, `plot`, `predict`, `print`, `residuals` and `summary` exist for this class.

All compulsory elements of `"glm"` and `"lm"` objects are present, but the fitting method for a GAM is different to a linear model or GLM, so that the elements relating to the QR decomposition of the model matrix are absent.

## Value

A gam object has the following elements:

|                           |                                                                                                                                                                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>aic</code>          | AIC of the fitted model: bear in mind that the degrees of freedom used to calculate this are the effective degrees of freedom of the model, and the likelihood is evaluated at the maximum of the penalized likelihood in most cases, not at the MLE. |
| <code>assign</code>       | Array whose elements indicate which model term (listed in <code>pterm</code> s) each parameter relates to: applies only to non-smooth terms.                                                                                                          |
| <code>boundary</code>     | did parameters end up at boundary of parameter space?                                                                                                                                                                                                 |
| <code>call</code>         | the matched call (allows update to be used with gam objects, for example).                                                                                                                                                                            |
| <code>cmX</code>          | column means of the model matrix (with elements corresponding to smooths set to zero) — useful for componentwise CI calculation.                                                                                                                      |
| <code>coefficients</code> | the coefficients of the fitted model. Parametric coefficients are first, followed by coefficients for each spline term in turn.                                                                                                                       |
| <code>control</code>      | the gam control list used in the fit.                                                                                                                                                                                                                 |
| <code>converged</code>    | indicates whether or not the iterative fitting method converged.                                                                                                                                                                                      |
| <code>data</code>         | the original supplied data argument (for class <code>"glm"</code> compatibility). Only included if <code>gam</code> control argument element <code>keepData</code> is set to TRUE (default is FALSE).                                                 |
| <code>db.drho</code>      | matrix of first derivatives of model coefficients w.r.t. log smoothing parameters.                                                                                                                                                                    |
| <code>deviance</code>     | model deviance (not penalized deviance).                                                                                                                                                                                                              |
| <code>df.null</code>      | null degrees of freedom.                                                                                                                                                                                                                              |
| <code>df.residual</code>  | effective residual degrees of freedom of the model.                                                                                                                                                                                                   |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| edf               | estimated degrees of freedom for each model parameter. Penalization means that many of these are less than 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| edf1              | similar, but using alternative estimate of EDF. Useful for testing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| edf2              | if estimation is by ML or REML then an edf that accounts for smoothing parameter uncertainty can be computed, this is it. edf1 is a heuristic upper bound for edf2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| family            | family object specifying distribution and link used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| fitted.values     | fitted model predictions of expected value for each datum.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| formula           | the model formula.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| full.sp           | full array of smoothing parameters multiplying penalties (excluding any contribution from min.sp argument to gam). May be larger than sp if some terms share smoothing parameters, and/or some smoothing parameter values were supplied in the sp argument of <a href="#">gam</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| F                 | Degrees of freedom matrix. This may be removed at some point, and should probably not be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| gcv.ubre          | The minimized smoothing parameter selection score: GCV, UBRE(AIC), GACV, negative log marginal likelihood or negative log restricted likelihood.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| hat               | array of elements from the leading diagonal of the ‘hat’ (or ‘influence’) matrix. Same length as response data vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| iter              | number of iterations of P-IRLS taken to get convergence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| linear.predictors | fitted model prediction of link function of expected value for each datum.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| method            | One of "GCV" or "UBRE", "REML", "P-REML", "ML", "P-ML", "PQL", "lme.ML" or "lme.REML", depending on the fitting criterion used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| mgcv.conv         | A list of convergence diagnostics relating to the "magic" parts of smoothing parameter estimation - this will not be very meaningful for pure "outer" estimation of smoothing parameters. The items are: full.rank, The apparent rank of the problem given the model matrix and constraints; rank, The numerical rank of the problem; fully.converged, TRUE is multiple GCV/UBRE converged by meeting convergence criteria and FALSE if method stopped with a steepest descent step failure; hess.pos.defWas the hessian of the GCV/UBRE score positive definite at smoothing parameter estimation convergence?; iter How many iterations were required to find the smoothing parameters? score.calls, and how many times did the GCV/UBRE score have to be evaluated?; rms.grad, root mean square of the gradient of the GCV/UBRE score at convergence. |
| min.edf           | Minimum possible degrees of freedom for whole model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| model             | model frame containing all variables needed in original model fit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| na.action         | The <a href="#">na.action</a> used in fitting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| nsdf              | number of parametric, non-smooth, model terms including the intercept.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| pterm           | terms object for strictly parametric part of model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| R               | Factor R from QR decomposition of weighted model matrix, unpivoted to be in same column order as model matrix (so need not be upper triangular).                                                                                                                                                                                                                                                                                                                                                                                                                              |
| rank            | apparent rank of fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| reml.scale      | The scale (RE)ML scale parameter estimate, if (P-)(RE)ML used for smoothness estimation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| residuals       | the working residuals for the fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| rV              | If present, $rV \% \% t(rV) * sig2$ gives the estimated Bayesian covariance matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| scale           | when present, the scale (as sig2)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| scale.estimated | TRUE if the scale parameter was estimated, FALSE otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| sig2            | estimated or supplied variance/scale parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| smooth          | list of smooth objects, containing the basis information for each term in the model formula in the order in which they appear. These smooth objects are what gets returned by the <a href="#">smooth.construct</a> objects.                                                                                                                                                                                                                                                                                                                                                   |
| sp              | estimated smoothing parameters for the model. These are the underlying smoothing parameters, subject to optimization. For the full set of smoothing parameters multiplying the penalties see <a href="#">full.sp</a> . Divide the scale parameter by the smoothing parameters to get, variance components, but note that this is not valid for smooths that have used rescaling to improve conditioning.                                                                                                                                                                      |
| terms           | terms object of model model frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| var.summary     | A named list of summary information on the predictor variables. If a parametric variable is a matrix, then the summary is a one row matrix, containing the observed data value closest to the column median, for each matrix column. If the variable is a factor the then summary is the modal factor level, returned as a factor, with levels corresponding to those of the data. For numerics and matrix arguments of smooths, the summary is the mean, nearest observed value to median and maximum, as a numeric vector. Used by <a href="#">vis.gam</a> , in particular. |
| Ve              | frequentist estimated covariance matrix for the parameter estimators. Particularly useful for testing whether terms are zero. Not so useful for CI's as smooths are usually biased.                                                                                                                                                                                                                                                                                                                                                                                           |
| Vp              | estimated covariance matrix for the parameters. This is a Bayesian posterior covariance matrix that results from adopting a particular Bayesian model of the smoothing process. Particularly useful for creating credible/confidence intervals.                                                                                                                                                                                                                                                                                                                               |
| Vc              | Under ML or REML smoothing parameter estimation it is possible to correct the covariance matrix Vp for smoothing parameter uncertainty. This is the corrected version.                                                                                                                                                                                                                                                                                                                                                                                                        |
| weights         | final weights used in IRLS iteration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| y               | response data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**WARNINGS**

This model object is different to that described in Chambers and Hastie (1993) in order to allow smoothing parameter estimation etc.

*Simulate example data for GAMs*

---

**Description**

Function used to simulate data sets to illustrate the use of [gam](#) and [gamm](#). Mostly used in help files to keep down the length of the example code sections.

**Usage**

```
gamSim(eg=1,n=400,dist="normal",scale=2,verbose=TRUE)
```

**Arguments**

|         |                                                                                 |
|---------|---------------------------------------------------------------------------------|
| eg      | numeric value specifying the example required.                                  |
| n       | number of data to simulate.                                                     |
| dist    | character string which may be used to specify the distribution of the response. |
| scale   | Used to set noise level.                                                        |
| verbose | Should information about simulation type be printed?                            |

## Details

See the source code for exactly what is simulated in each case.

1. Gu and Wahba 4 univariate term example.
2. A smooth function of 2 variables.
3. Example with continuous by variable.
4. Example with factor by variable.
5. An additive example plus a factor variable.
6. Additive + random effect.
7. As 1 but with correlated covariates.

## Value

Depends on eg, but usually a dataframe, which may also contain some information on the underlying truth. Sometimes a list with more items, including a data frame for model fitting. See source code or helpfile examples where the function is used for further information.

|--------|---------------------------------------------|
| gaulss | <i>Gaussian location-scale model family</i> |
|--------|---------------------------------------------|

---

## Description

The gaulss family implements Gaussian location scale additive models in which the mean and the logb of the standard deviation (see details) can depend on additive smooth predictors. Useable only with [gam](#), the linear predictors are specified via a list of formulae.

## Usage

```
gaulss(link=list("identity", "logb"), b=0.01)
```

## Arguments

- |      |                                                                                         |
|------|-----------------------------------------------------------------------------------------|
| link | two item list specifying the link for the mean and the standard deviation. See details. |
| b    | The minumum standard deviation, for the "logb" link.                                    |

## Details

Used with `gam` to fit Gaussian location - scale models. `gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the mean on the right hand side. The second is one sided, specifying the linear predictor for the standard deviation on the right hand side.

Link functions "identity", "inverse", "log" and "sqrt" are available for the mean. For the standard deviation only the "logb" link is implemented:  $\eta = \log(\sigma - b)$  and  $\sigma = b + \exp(\eta)$ . This link is designed to avoid singularities in the likelihood caused by the standard deviation tending to zero. Note that internally the family is parameterized in terms of the  $\tau = \sigma^{-1}$ , i.e. the standard deviation of the precision, so the link and inverse link are coded to reflect this, however the relationships between the linear predictor and the standard deviation are as given above.

The fitted values for this family will be a two column matrix. The first column is the mean, and the second column is the inverse of the standard deviation. Predictions using `predict.gam` will also produce 2 column matrices for type "link" and "response". The second column when type="response" is again on the reciprocal standard deviation scale (i.e. the square root precision scale). The second column when type="link" is  $\log(\sigma - b)$ . Also `plot.gam` will plot smooths relating to  $\sigma$  on the  $\log(\sigma - b)$  scale (so high values correspond to high standard deviation and low values to low standard deviation). Similarly the smoothing penalties are applied on the (log) standard deviation scale, not the log precision scale.

The null deviance reported for this family is the sum of squares of the difference between the response and the mean response divided by the standard deviation of the response according to the model. The deviance is the sum of squares of residuals divided by model standard deviations.

## Value

An object inheriting from class `general.family`.

## Examples

```
library(mgcv);library(MASS)
b <- gam(list(accel~s(times,k=20,bs="ad"),~s(times)),
 data=mcycle,family=gaulss())
summary(b)
plot(b,pages=1,scale=0)
```

---

get.var

*Get named variable or evaluate expression from list or data.frame*

---

## Description

This routine takes a text string and a data frame or list. It first sees if the string is the name of a variable in the data frame/ list. If it is then the value of this variable is returned. Otherwise the routine tries to evaluate the expression within the data.frame/list (but nowhere else) and if successful returns the result. If neither step works then NULL is returned. The routine is useful for processing gam formulae. If the variable is a matrix then it is coerced to a numeric vector, by default.

**Usage**

```
get.var(txt,data,vecMat=TRUE)
```

**Arguments**

|        |                                                                                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| txt    | a text string which is either the name of a variable in data or when parsed is an expression that can be evaluated in data. It can also be neither in which case the function returns NULL. |
| data   | A data frame or list.                                                                                                                                                                       |
| vecMat | Should matrices be coerced to numeric vectors?                                                                                                                                              |

**Value**

The evaluated variable or NULL. May be coerced to a numeric vector if it's a matrix.

---

gevlss

*Generalized Extreme Value location-scale model family*

---

**Description**

The gevlss family implements Generalized Extreme Value location scale additive models in which the location, scale and shape parameters depend on additive smooth predictors. Usable only with [gam](#), the linear predictors are specified via a list of formulae.

**Usage**

```
gevlss(link=list("identity","identity","logit"))
```

**Arguments**

|      |                                                                                               |
|------|-----------------------------------------------------------------------------------------------|
| link | three item list specifying the link for the location scale and shape parameters. See details. |
|------|-----------------------------------------------------------------------------------------------|

## Details

Used with `gam` to fit Generalized Extreme Value distribution location scale and shape models. The p.d.f. is

$$t(y)^{\xi+1}e^{-t(y)}/\sigma$$

where  $t(y) = \{1 + \xi(y - \mu)/\sigma\}^{-1/\xi}$  if  $\xi \neq 0$  and  $t(y) = \exp\{-(y - \mu)/\sigma\}$  if  $\xi = 0$ .

`gam` is called with a list containing 3 formulae: the first specifies the response on the left hand side and the structure of the linear predictor for the location parameter,  $\mu$ , on the right hand side. The second is one sided, specifying the linear predictor for the log scale parameter,  $\rho = \log(\sigma)$ , on the right hand side. The third is one sided specifying the linear predictor for the shape parameter,  $\xi$ .

Link functions "identity" and "log" are available for the location ( $\mu$ ) parameter. There is no choice of link for the log scale parameter ( $\rho = \log(\sigma)$ ). The shape parameter ( $\xi$ ) defaults to a modified logit link restricting its range to (-1,.5), the upper limit is required to ensure finite variance, while the lower limit ensures consistency of the MLE (Smith, 1985).

The fitted values for this family will be a three column matrix. The first column is the location parameter, the second column is the log scale parameter, the third column is the shape parameter.

This family does not produce a null deviance. Note that the distribution for  $\xi = 0$  is approximated by setting  $\xi$  to a small number.

The derivative system code for this family is mostly auto-generated, and the family is still somewhat experimental.

The GEV distribution is rather challenging numerically, and for small datasets or poorly fitting models improved numerical robustness may be obtained by using the extended Fellner-Schall method of Wood and Fasiolo (2017) for smoothing parameter estimation. See examples.

## Value

An object inheriting from class `general.family`.

---

gfam

*Grouped families*

---

## Description

Family for use with [gam](#) or [bam](#) allowing a univariate response vector to be made up of variables from several different distributions. The response variable is supplied as a 2 column matrix, where the first column contains the response observations and the second column indexes the distribution (family) from which it comes. `gfam` takes a list of families as its single argument.

Useful for modelling data from different sources that are linked by a model sharing some components. Smooth model components that are not shared are usually handled with by variables (see [gam.models](#)).

## Usage

```
gfam(fl)
```

## Arguments

**f1** A list of families. These can be any families inheriting from `family` or `extended.family` usable with `gam`, provided that they do not usually require a matrix response variable.

## Details

Each component function of `gfam` uses the families supplied in the list `f1` to obtain the required quantities for that family's subset of data, and combines the results appropriately. For example it provides the total deviance (twice negative log-likelihood) of the model, along with its derivatives, by computing the family specific deviance and derivatives from each family applied to its subset of data, and summing them. Other quantities are computed in the same way.

Regular exponential families do not compute the same quantities as extended families, so `gfam` converts what these families produce to `extended.family` form internally.

Scale parameters obviously have to be handled separately for each family, and treated as parameters to be estimated, just like other `extended.family` non-location distribution parameters. Again this is handled internally. This requirement is part of the reason that an `extended.family` is always produced, even if all elements of `f1` are standard exponential families. In consequence smoothing parameter estimation is always by REML or NCV.

Note that the null deviance is currently computed by assuming a single parameter model for each family, rather than just one parameter, which may slightly lower explained deviances. Note also that residual checking should probably be done by disaggregating the residuals by family. For this reason functions are not provided to facilitate residual checking with `qq.gam`.

Prediction on the response scale requires that a family index vector is supplied, with the name of the response, as part of the new prediction data. However, families such as `ocat` which usually produce matrix predictions for prediction type "response", will not be able to do so when part of `gfam`.

`gfam` relies on the methods in Wood, Pya and Saeften (2016).

## Value

An object of class `extended.family`.

```

## Description

Apply Integrated Nested Laplace Approximation (INLA, Rue et al. 2009) to models estimable by `gam` or `bam`, using the INLA variant described in Wood (2019). Produces marginal posterior densities for each coefficient, selected coefficients or linear transformations of the coefficient vector.

## Usage

```
ginla(G,A=NULL,nk=16,nb=100,J=1,interactive=FALSE,integ=0,approx=0)
```

## Arguments

|             |                                                                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| G           | A pre-fit gam object, as produced by <code>gam(...,fit=FALSE)</code> or <code>bam(...,discrete=TRUE,fit=FALSE)</code> .                                                                                                                                            |
| A           | Either a matrix whose rows are transforms of the coefficients that are of interest (no more rows than columns, full row rank), or an array of indices of the parameters of interest. If NULL then distributions are produced for all coefficients.                 |
| nk          | Number of values of each coefficient at which to evaluate its log marginal posterior density. These points are then spline interpolated.                                                                                                                           |
| nb          | Number of points at which to evaluate posterior density of coefficients for returning as a gridded function.                                                                                                                                                       |
| J           | How many determinant updating steps to take in the log determinant approximation step. Not recommended to increase this.                                                                                                                                           |
| interactive | If this is >0 or TRUE then every approximate posterior is plotted in red, overlaid on the simple Gaussian approximate posterior. If 2 then waits for user to press return between each plot. Useful for judging whether anything is gained by using INLA approach. |
| integ       | 0 to skip integration and just use the posterior modal smoothing parameter. >0 for integration using the CCD approach proposed in Rue et al. (2009).                                                                                                               |
| approx      | 0 for full approximation; 1 to update Hessian, but use approximate modes; 2 as 1 and assume constant Hessian. See details.                                                                                                                                         |

## Details

Let  $\beta$ ,  $\theta$  and  $y$  denote the model coefficients, hyperparameters/smoothing parameters and response data, respectively. In principle, INLA employs Laplace approximations for  $\pi(\beta_i|\theta, y)$  and  $\pi(\theta|y)$  and then obtains the marginal posterior distribution  $\pi(\beta_i|y)$  by integrating the approximations to  $\pi(\beta_i|\theta, y)\pi(\theta|y)$  w.r.t  $\theta$  (marginals for the hyperparameters can also be produced). In practice the Laplace approximation for  $\pi(\beta_i|\theta, y)$  is too expensive to compute for each  $\beta_i$  and must itself be approximated. To this end, there are two quantities that have to be computed: the posterior mode  $\beta^*|\beta_i$  and the determinant of the Hessian of the joint log density  $\log \pi(\beta, \theta, y)$  w.r.t.  $\beta$  at the mode. Rue et al. (2009) originally approximated the posterior conditional mode by the conditional mode implied by a simple Gaussian approximation to the posterior  $\pi(\beta|y)$ . They then approximated the log determinant of the Hessian as a function of  $\beta_i$  using a first order Taylor expansion, which is cheap to compute for the sparse model representation that they use, but not when using the dense low rank basis expansions used by `gam`. They also offer a more expensive alternative approximation based on computing the log determinant with respect only to those elements of  $\beta$  with sufficiently high correlation with  $\beta_i$  according to the simple Gaussian posterior approximation: efficiency again seems to rest on sparsity. Wood (2020) suggests computing the required posterior modes exactly, and basing the log determinant approximation on a BFGS update of the Hessian at the unconditional

model. The latter is efficient with or without sparsity, whereas the former is a ‘for free’ improvement. Both steps are efficient because it is cheap to obtain the Cholesky factor of  $H[-i, -i]$  from that of  $H$  - see [choldrop](#). This is the approach taken by this routine.

The `approx` argument allows two further approximations to speed up computations. For `approx==1` the exact posterior conditional modes are not used, but instead the conditional modes implied by the simple Gaussian posterior approximation. For `approx==2` the same approximation is used for the modes and the Hessian is assumed constant. The latter is quite fast as no log joint density gradient evaluations are required.

Note that for many models the INLA estimates are very close to the usual Gaussian approximation to the posterior, the `interactive` argument is useful for investigating this issue.

[bam](#) models are only supported with the `discrete=TRUE` option. The `discrete=FALSE` approach would be too inefficient. AR1 models are not supported (related arguments are simply ignored).

### Value

A list with elements `beta` and `density`, both of which are matrices. Each row relates to one coefficient (or linear coefficient combination) of interest. Both matrices have `nb` columns. If `int!=0` then a further element `reml` gives the integration weights used in the CCD integration, with the central point weight given first.

### WARNINGS

This routine is still somewhat experimental, so details are liable to change. Also currently not all steps are optimally efficient.

The routine is written for relatively expert users.

`ginla` is not designed to deal with rank deficient models.

### Examples

```
require(mgcv); require(MASS)

example using a scale location model for the motorcycle data. A simple
plotting routine is produced first...

plot.inla <- function(x,inla,k=1,levels=c(.025,.1,.5,.9,.975),
 lcol = c(2,4,4,4,2),lwd = c(1,1,2,1,1),lty=c(1,1,1,1,1),
 xlab="x",ylab="y",cex.lab=1.5) {
 ## a simple effect plotter, when distributions of function values of
 ## 1D smooths have been computed
 require(splines)
```

```

p <- length(x)
betaq <- matrix(0,length(levels),p) ## storage for beta quantiles
for (i in 1:p) { ## work through x and betas
 j <- i + k - 1
 p <- cumsum(inla$density[j,])*(inla$beta[j,2]-inla$beta[j,1])
 ## getting quantiles of function values...
 betaq[,i] <- approx(p,y=inla$beta[j,],levels)$y
}
xg <- seq(min(x),max(x),length=200)
ylim <- range(betaq)
ylim <- 1.1*(ylim-mean(ylim))+mean(ylim)
for (j in 1:length(levels)) { ## plot the quantiles
 din <- interpSpline(x,betaq[j,])
 if (j==1) {
 plot(xg,predict(din,xg)$y,ylim=ylim,type="l",col=lcol[j],
 xlab=xlab,ylab=ylab,lwd=lwd[j],cex.lab=1.5,lty=lty[j])
 } else lines(xg,predict(din,xg)$y,col=lcol[j],lwd=lwd[j],lty=lty[j])
}
} ## plot.inla

set up the model with a `gam' call...

G <- gam(list(accel~s(times,k=20,bs="ad"),~s(times)),
 data=mcycle,family=gaulss(),fit=FALSE)
b <- gam(G,method="REML") ## regular GAM fit for comparison

Now use ginla to get posteriors of estimated effect values
at evenly spaced times. Create A matrix for this...

rat <- range(mcycle$times)
pd0 <- data.frame(times=seq(rat[1],rat[2],length=20))
X0 <- predict(b,newdata=pd0,type="lpmatrix")
X0[,21:30] <- 0
pd1 <- data.frame(times=seq(rat[1],rat[2],length=10))
X1 <- predict(b,newdata=pd1,type="lpmatrix")
X1[,1:20] <- 0
A <- rbind(X0,X1) ## A maps coefs to required function values

call ginla. Set integ to 1 for integrated version.
Set interactive = 1 or 2 to plot marginal posterior distributions
(red) and simple Gaussian approximation (black).

inla <- ginla(G,A,integ=0)

par(mfrow=c(1,2),mar=c(5,5,1,1))
fv <- predict(b,se=TRUE) ## usual Gaussian approximation, for comparison

plot inla mean smooth effect...
plot.inla(pd0$times,inla,k=1,xlab="time",ylab=expression(f[1](time)))

overlay simple Gaussian equivalent (in grey) ...
points(mcycle$times,mcycle$accel,col="grey")
lines(mcycle$times,fv$fit[,1],col="grey",lwd=2)
lines(mcycle$times,fv$fit[,1]+2*fv$se.fit[,1],lty=2,col="grey",lwd=2)
lines(mcycle$times,fv$fit[,1]-2*fv$se.fit[,1],lty=2,col="grey",lwd=2)

same for log sd smooth...

```

```

plot.inla(pd1$times,inla,k=21,xlab="time",ylab=expression(f[2](time)))
lines(mcycle$times,fv$fit[,2],col="grey",lwd=2)
lines(mcycle$times,fv$fit[,2]+2*fv$se.fit[,2],col="grey",lty=2,lwd=2)
lines(mcycle$times,fv$fit[,2]-2*fv$se.fit[,2],col="grey",lty=2,lwd=2)

... notice some real differences for the log sd smooth, especially
at the lower and upper ends of the time interval.

```

gumb1s

*Gumbel location-scale model family*

## Description

The `gumb1s` family implements Gumbel location scale additive models in which the location and scale parameters (see details) can depend on additive smooth predictors. Useable only with `gam`, the linear predictors are specified via a list of formulae.

## Usage

```
gumb1s(link=list("identity","log"),b=-7)
```

## Arguments

|                   |                                                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>link</code> | two item list specifying the link for the location $\mu$ and log scale parameter $\beta$ . See details for meaning, which may not be intuitive. |
| <code>b</code>    | The minimum log scale parameter.                                                                                                                |

## Details

Let  $z = (y - \mu)e^{-\beta}$ , then the log Gumbel density is  $l = -\beta - z - e^{-z}$ . The expected value of a Gumbel r.v. is  $\mu + \gamma e^{\beta}$  where  $\gamma$  is Eulers constant (about 0.57721566). The corresponding variance is  $\pi^2 e^{2\beta} / 6$ .

`gumb1s` is used with `gam` to fit Gumbel location - scale models parameterized in terms of location parameter  $\mu$  and the log scale parameter  $\beta$ . Note that `identity` link for the scale parameter means that the corresponding linear predictor gives  $\beta$  directly. By default the `log` link for the scale parameter simply forces the log scale parameter to have a lower limit given by argument `b`: if  $\eta$  is the linear predictor for the log scale parameter,  $\beta$ , then  $\beta = b + \log(1 + e^{\eta-b})$ .

`gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for location parameter,  $\mu$ , on the right hand side. The second is one sided, specifying the linear predictor for the log scale,  $\beta$ , on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the mean, and the second column is the log scale parameter,  $\beta$ . Predictions using `predict.gam` will also produce 2 column matrices for type `"link"` and `"response"`. The first column is on the original data scale when type=`"response"` and on the log mean scale of the linear predictor when type=`"link"`. The second column when type=`"response"` is again the log scale parameter, but is on the linear predictor when type=`"link"`.

## Value

An object inheriting from class `general.family`.

## Examples

```
library(mgcv)
simulate some data
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x) exp(2 * x)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
n <- 400; set.seed(9)
x0 <- runif(n); x1 <- runif(n);
x2 <- runif(n); x3 <- runif(n);
mu <- f0(x0) + f1(x1)
beta <- exp(f2(x2)/5)
y <- mu - beta * log(-log(runif(n))) ## Gumbel quantile function

b <- gam(list(y ~ s(x0) + s(x1), ~ s(x2) + s(x3)), family = gumbles)
plot(b, pages = 1, scale = 0)
summary(b)
gam.check(b)
```

---

identifiability

*Identifiability constraints*

---

## Description

Smooth terms are generally only identifiable up to an additive constant. In consequence sum-to-zero identifiability constraints are imposed on most smooth terms. The exceptions are terms with by variables which cause the smooth to be identifiable without constraint (that doesn't include factor by variables), and random effect terms. Alternatively smooths can be set up to pass through zero at a user specified point.

## Details

By default each smooth term is subject to the sum-to-zero constraint

$$\sum_i f(x_i) = 0.$$

The constraint is imposed by reparameterization. The sum-to-zero constraint causes the term to be orthogonal to the intercept: alternative constraints lead to wider confidence bands for the constrained smooth terms.

No constraint is used for random effect terms, since the penalty (random effect covariance matrix) anyway ensures identifiability in this case. Also if a by variable means that the smooth is anyway identifiable, then no extra constraint is imposed. Constraints are imposed for factor by variables, so that the main effect of the factor must usually be explicitly added to the model (the example below is an exception).

Occasionally it is desirable to substitute the constraint that a particular smooth curve should pass through zero at a particular point: the `pc` argument to `s`, `te`, `ti` and `t2` allows this: if specified then such constraints are always applied.

### Examples

```
Example of three groups, each with a different smooth dependence on x
but each starting at the same value...
require(mgcv)
set.seed(53)
n <- 100; x <- runif(3*n); z <- runif(3*n)
fac <- factor(rep(c("a", "b", "c"), each=100))
y <- c(sin(x[1:100]*4), exp(3*x[101:200])/10-.1, exp(-10*(x[201:300]-.5))/
 (1+exp(-10*(x[201:300]-.5)))-0.9933071) + z*(1-z)*5 + rnorm(100)*.4

'pc' used to constrain smooths to 0 at x=0...
b <- gam(y~s(x,by=fac,pc=0)+s(z))
plot(b,pages=1)
```

---

in.out

---

*Which of a set of points lie within a polygon defined region*

---

### Description

Tests whether each of a set of points lie within a region defined by one or more (possibly nested) polygons. Points count as ‘inside’ if they are interior to an odd number of polygons.

### Usage

```
in.out(bnd, x)
```

### Arguments

|     |                                                                                                                                                                                                                                                                                                                                       |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bnd | A two column matrix, the rows of which define the vertices of polygons defining the boundary of a region. Different polygons should be separated by an NA row, and the polygons are assumed closed. Alternatively can be a lists where <code>bnd[[i]][[1]]</code> , <code>bnd[[i]][[2]]</code> defines the <i>i</i> th boundary loop. |
| x   | A two column matrix. Each row is a point to test for inclusion in the region defined by bnd. Can also be a 2-vector, defining a single point.                                                                                                                                                                                         |

### Details

The algorithm works by counting boundary crossings (using compiled C code).

### Value

A logical vector of length `nrow(x)`. TRUE if the corresponding row of `x` is inside the boundary and FALSE otherwise.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

```
library(mgcv)
data(columb.polys)
bnd <- columb.polys[[2]]
plot(bnd,type="n")
polygon(bnd)
x <- seq(7.9,8.7,length=20)
y <- seq(13.7,14.3,length=20)
gr <- as.matrix(expand.grid(x,y))
inside <- in.out(bnd,gr)
points(gr,col=as.numeric(inside)+1)
```

---

influence.gam

*Extract the diagonal of the influence/hat matrix for a GAM*

---

**Description**

Extracts the leading diagonal of the influence matrix (hat matrix) of a fitted gam object.

**Usage**

```
S3 method for class 'gam'
influence(model,...)
```

**Arguments**

|       |                                                         |
|-------|---------------------------------------------------------|
| model | fitted model objects of class gam as produced by gam(). |
| ...   | un-used in this case                                    |

**Details**

Simply extracts hat array from fitted model. (More may follow!)

**Value**

An array (see above).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

[gam](#)

initial.sp

*Starting values for multiple smoothing parameter estimation***Description**

Finds initial smoothing parameter guesses for multiple smoothing parameter estimation. The idea is to find values such that the estimated degrees of freedom per penalized parameter should be well away from 0 and 1 for each penalized parameter, thus ensuring that the values are in a region of parameter space where the smoothing parameter estimation criterion is varying substantially with smoothing parameter value.

**Usage**

```
initial.sp(X,S,off,expensive=FALSE,XX=FALSE)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X         | is the model matrix.                                                                                                                                                                                                                                                                                                                                                   |
| S         | is a list of of penalty matrices. $S[[i]]$ is the $i$ th penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of $S[[i]]$ occupies element $off[i]$ , $off[i]$ of the $i$ th penalty matrix. Each $S[[i]]$ must be positive semi-definite. |
| off       | is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving $S[[i]]$ .                                                                                                                                                                                                                                               |
| expensive | if TRUE then the overall amount of smoothing is adjusted so that the average degrees of freedom per penalized parameter is exactly 0.5: this is numerically costly.                                                                                                                                                                                                    |
| XX        | if TRUE then X contains $X^T X$ , rather than $X$ .                                                                                                                                                                                                                                                                                                                    |

**Details**

Basically uses a crude approximation to the estimated degrees of freedom per model coefficient, to try and find smoothing parameters which bound these e.d.f.'s away from 0 and 1.

Usually only called by [magic](#) and [gam](#).

**Value**

An array of initial smoothing parameter estimates.

**Author(s)**

inSide

---

*Are points inside boundary?*

---

### Description

Assesses whether points are inside a boundary. The boundary must enclose the domain, but may include islands.

### Usage

```
inSide(bnd,x,y,xname=NULL,yname=NULL)
```

### Arguments

|       |                                                                                                                                                                                                                                                                                |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bnd   | This should have two equal length columns with names matching whatever is supplied in x and y. This may contain several sections of boundary separated by NA. Alternatively bnd may be a list, each element of which contains 2 columns named as above. See below for details. |
| x     | x co-ordinates of points to be tested.                                                                                                                                                                                                                                         |
| y     | y co-ordinates of points to be tested.                                                                                                                                                                                                                                         |
| xname | name of variable in bnd that x relates to. Defaults to name of variable supplied as x.                                                                                                                                                                                         |
| yname | name of variable in bnd that y relates to. Defaults to name of variable supplied as y.                                                                                                                                                                                         |

### Details

Segments of boundary are separated by NAs, or are in separate list elements. The boundary co-ordinates are taken to define nodes which are joined by straight line segments in order to create the boundary. Each segment is assumed to define a closed loop, and the last point in a segment will be assumed to be joined to the first. Loops must not intersect (no test is made for this).

The method used is to count how many times a line, in the y-direction from a point, crosses a boundary segment. An odd number of crossings defines an interior point. Hence in geographic applications it would be usual to have an outer boundary loop, possibly with some inner 'islands' completely enclosed in the outer loop.

The routine calls compiled C code and operates by an exhaustive search for each point in x, y.

### Value

The function returns a logical array of the same dimension as x and y. TRUE indicates that the corresponding x, y point lies inside the boundary.

## Examples

```
require(mgcv)
m <- 300; n <- 150
xm <- seq(-1,4,length=m); yn <- seq(-1,1,length=n)
x <- rep(xm,n); y <- rep(yn,rep(m,n))
er <- matrix(fs.test(x,y),m,n)
bnd <- fs.boundary()
in.bnd <- inSide(bnd,x,y)
plot(x,y,col=as.numeric(in.bnd)+1,pch=".")
lines(bndx,bndy,col=3)
points(x,y,col=as.numeric(in.bnd)+1,pch=".")
check boundary details ...
plot(x,y,col=as.numeric(in.bnd)+1,pch=".",ylim=c(-1,0),xlim=c(3,3.5))
lines(bndx,bndy,col=3)
points(x,y,col=as.numeric(in.bnd)+1,pch=".")

alternatively, give the names of x and y
d <- data.frame(x, y); rm(x, y)
in.bnd2 <- inSide(bnd, dx, dy, xname="x", yname="y")
all.equal(in.bnd, in.bnd2)
```

---

interpret.gam

*Interpret a GAM formula*

---

## Description

This is an internal function of package mgcv. It is a service routine for gam which splits off the strictly parametric part of the model formula, returning it as a formula, and interprets the smooth parts of the model formula.

Not normally called directly.

## Usage

```
interpret.gam(gf, extra.special = NULL)
```

## Arguments

|               |                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| gf            | A GAM formula as supplied to <a href="#">gam</a> or <a href="#">gamm</a> , or a list of such formulae, as supplied for some <a href="#">gam</a> families. |
| extra.special | Name of any extra special in formula in addition to s, te, ti and t2.                                                                                     |

## Value

An object of class `split.gam.formula` with the following items:

|             |                                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pf          | A model formula for the strictly parametric part of the model.                                                                                                                                                              |
| pfok        | TRUE if there is a pf formula.                                                                                                                                                                                              |
| smooth.spec | A list of class <code>xx.smooth.spec</code> objects where <code>xx</code> depends on the basis specified for the term. (These can be passed to smooth constructor method functions to actually set up penalties and bases.) |

|                           |                                                                                                                                                                  |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>full.formula</code> | An expanded version of the model formula in which the options are fully expanded, and the options do not depend on variables which might not be available later. |
| <code>fake.formula</code> | A formula suitable for use in evaluating a model frame.                                                                                                          |
| <code>response</code>     | Name of the response variable.                                                                                                                                   |

jagam

---

*Just Another Gibbs Additive Modeller: JAGS support for mgcv.*

---

**Description**

Facilities to auto-generate model specification code and associated data to simulate with GAMs in JAGS (or BUGS). This is useful for inference about models with complex random effects structure best coded in JAGS. It is a very inefficient approach to making inferences about standard GAMs. The idea is that `jagam` generates template JAGS code, and associated data, for the smooth part of the model. This template is then directly edited to include other stochastic components. After simulation with the resulting model, facilities are provided for plotting and prediction with the model smooth components.

**Usage**

```
jagam(formula,family=gaussian,data=list(),file,weights=NULL,na.action,
offset=NULL,knots=NULL,sp=NULL,drop.unused.levels=TRUE,
control=gam.control(),centred=TRUE,sp.prior = "gamma",diagonalize=FALSE)
```

```
sim2jam(sam,pregam,edf.type=2,burnin=0)
```

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code> | A GAM formula (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). This is exactly like the formula for a GLM except that smooth terms, <code>s</code> , <code>te</code> , <code>ti</code> and <code>t2</code> can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these). |
| <code>family</code>  | This is a family object specifying the distribution and link function to use. See <a href="#">glm</a> and <a href="#">family</a> for more details. Currently only <code>gaussian</code> , <code>poisson</code> , <code>binomial</code> and <code>Gamma</code> families are supported, but the user can easily modify the assumed distribution in the JAGS code.                        |
| <code>data</code>    | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>jagam</code> is called.                                                                                                                                     |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file               | Name of the file to which JAGS model specification code should be written. See <a href="#">setwd</a> for setting and querying the current working directory.                                                                                                                                                                                                                                                                                                                      |
| weights            | prior weights on the data.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| na.action          | a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.                                                                                                                                                                                                                                                               |
| offset             | Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula: this conforms to the behaviour of <code>lm</code> and <code>glm</code> .                                                                                                                                                                                                                                  |
| control            | A list of fit control parameters to replace defaults returned by <a href="#">gam.control</a> . Any control parameters not supplied stay at their default values. little effect on jagam.                                                                                                                                                                                                                                                                                          |
| knots              | this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the <code>k</code> value supplied (note that the number of knots is not always just <code>k</code> ). See <a href="#">tprs</a> for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.                                |
| sp                 | A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula (without forgetting null space penalties). Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters. |
| drop.unused.levels | by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.                                                                                                                                                                                                                                                                                         |
| centred            | Should centring constraints be applied to the smooths, as is usual with GAMS? Only set this to FALSE if you know exactly what you are doing. If FALSE there is a (usually global) intercept for each smooth.                                                                                                                                                                                                                                                                      |
| sp.prior           | "gamma" or "log.uniform" prior for the smoothing parameters? Do check that the default parameters are appropriate for your model in the JAGS code.                                                                                                                                                                                                                                                                                                                                |
| diagonalize        | Should smooths be re-parameterized to have i.i.d. Gaussian priors (where possible)? For Gaussian data this allows efficient conjugate samplers to be used, and it can also work well with GLMs if the JAGS "glm" module is loaded, but otherwise it is often better to update smoothers blockwise, and not do this.                                                                                                                                                               |
| sam                | jags sample object, containing at least fields <code>b</code> (coefficients) and <code>rho</code> (log smoothing parameters). May also contain field <code>mu</code> containing monitored expected response.                                                                                                                                                                                                                                                                      |
| pregam             | standard mgcv GAM setup data, as returned in jagam return list.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| edf.type           | Since EDF is not uniquely defined and may be affected by the stochastic structure added to the JAGS model file, 3 options are offered. See details.                                                                                                                                                                                                                                                                                                                               |
| burnin             | the amount of burn in to discard from the simulation chains. Limited to .9 of the chain length.                                                                                                                                                                                                                                                                                                                                                                                   |

## Details

Smooths are easily incorporated into JAGS models using multivariate normal priors on the smooth coefficients. The smoothing parameters and smoothing penalty matrices directly specify the prior

multivariate normal precision matrix. Normally a smoothing penalty does not correspond to a full rank precision matrix, implying an improper prior inappropriate for Gibbs sampling. To rectify this problem the null space penalties suggested in Marra and Wood (2011) are added to the usual penalties.

In an additive modelling context it is usual to centre the smooths, to avoid the identifiability issues associated with having an intercept for each smooth term (in addition to a global intercept). Under Gibbs sampling with JAGS it is technically possible to omit this centring, since we anyway force propriety on the priors, and this propriety implies formal model identifiability. However, in most situations this formal identifiability is rather artificial and does not imply statistically meaningful identifiability. Rather it serves only to massively inflate confidence intervals, since the multiple intercept terms are not identifiable from the data, but only from the prior. By default then, *jagam* imposes standard GAM identifiability constraints on all smooths. The centred argument does allow you to turn this off, but it is not recommended. If you do set `centred=FALSE` then chain convergence and mixing checks should be particularly stringent.

The final technical issue for model setup is the setting of initial conditions for the coefficients and smoothing parameters. The approach taken is to take the default initial smoothing parameter values used elsewhere by *mgcv*, and to take a single PIRLS fitting step with these smoothing parameters in order to obtain starting values for the smooth coefficients. In the setting of fully conjugate updating the initial values of the coefficients are not critical, and good results are obtained without supplying them. But in the usual setting in which slice sampling is required for at least some of the updates then very poor results can sometimes be obtained without initial values, as the sampler simply fails to find the region of the posterior mode.

The *sim2jam* function takes the partial gam object (*pregam*) from *jagam* along with simulation output in standard *rjags* form and creates a reduced version of a gam object, suitable for plotting and prediction of the model's smooth components. *sim2gam* computes effective degrees of freedom for each smooth, but it should be noted that there are several possibilities for doing this in the context of a model with a complex random effects structure. The simplest approach (`edf.type=0`) is to compute the degrees of freedom that the smooth would have had if it had been part of an unweighted Gaussian additive model. One might choose to use this option if the model has been modified so that the response distribution and/or link are not those that were specified to *jagam*. The second option is (`edf.type=1`) uses the edf that would have been computed by *gam* had it produced these estimates - in the context in which the JAGS model modifications have all been about modifying the random effects structure, this is equivalent to simply setting all the random effects to zero for the effective degrees of freedom calculation. The default option (`edf.type=2`) is to base the EDF on the sample covariance matrix, *Vp*, of the model coefficients. If the simulation output (*sim*) includes a *mu* field, then this will be used to form the weight matrix *W* in  $XWX = t(X) \%*\% W \%* X$ , where the EDF is computed from  $\text{rowSums}(Vp * XWX) * \text{scale}$ . If *mu* is not supplied then it is estimated from the the model matrix *X* and the mean of the simulated coefficients, but the resulting *W* may not be strictly compatible with the *Vp* matrix in this case. In the situation in which the fitted model is very different in structure from the regression model of the template produced by *jagam* then the default option may make no sense, and indeed it may be best to use option 0.

## Value

For *jagam* a three item list containing

|                  |                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------|
| <i>pregam</i>    | standard <i>mgcv</i> GAM setup data.                                                               |
| <i>jags.data</i> | list of arguments to be supplied to JAGS containing information referenced in model specification. |
| <i>jags.ini</i>  | initialization data for smooth coefficients and smoothing parameters.                              |

For *sim2jam* an object of class "jam": a partial version of an *mgcv* *gamObject*, suitable for plotting and predicting.

## WARNINGS

Gibb's sampling is a very slow inferential method for standard GAMs. It is only likely to be worthwhile when complex random effects structures are required above what is possible with direct GAMM methods.

Check that the parameters of the priors on the parameters are fit for your purpose.

## Examples

```
the following illustrates a typical workflow. To run the
'Not run' code you need rjags (and JAGS) to be installed.
require(mgcv)

set.seed(2) ## simulate some data...
n <- 400
dat <- gamSim(1,n=n,dist="normal",scale=2)
regular gam fit for comparison...
b0 <- gam(y~s(x0)+s(x1) + s(x2)+s(x3),data=dat,method="REML")

Set directory and file name for file containing jags code.
In real use you would *never* use tempdir() for this. It is
only done here to keep CRAN happy, and avoid any chance of
an accidental overwrite. Instead you would use
setwd() to set an appropriate working directory in which
to write the file, and just set the file name to what you
want to call it (e.g. "test.jags" here).

jags.file <- paste(tempdir(),"/test.jags",sep="")

Set up JAGS code and data. In this one might want to diagonalize
to use conjugate samplers. Usually call 'setwd' first, to set
directory in which model file ("test.jags") will be written.

jd <- jagam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat,file=jags.file,
 sp.prior="gamma",diagonalize=TRUE)
```

```

In normal use the model in "test.jags" would now be edited to add
the non-standard stochastic elements that require use of JAGS....

Not run:
require(rjags)
load.module("glm") ## improved samplers for GLMs often worth loading
jm <- jags.model(jags.file,data=jd$jags.data,init=jd$jags.ini,n.chains=1)
list.samplers(jm)
sam <- jags.samples(jm,c("b","rho","scale"),n.iter=10000,thin=10)
jam <- sim2jam(sam,jd$pregam)
plot(jam,pages=1)
jam
pd <- data.frame(x0=c(.5,.6),x1=c(.4,.2),x2=c(.8,.4),x3=c(.1,.1))
fv <- predict(jam,newdata=pd)
and some minimal checking...
require(coda)
effectiveSize(as.mcmc.list(sam$b))

End(Not run)

a gamma example...
set.seed(1); n <- 400
dat <- gamSim(1,n=n,dist="normal",scale=2)
scale <- .5; Ey <- exp(dat$f/2)
dat$y <- rgamma(n,shape=1/scale,scale=Ey*scale)
jd <- jagam(y~s(x0)+te(x1,x2)+s(x3),data=dat,family=Gamma(link=log),
 file=jags.file,sp.prior="log.uniform")

In normal use the model in "test.jags" would now be edited to add
the non-standard stochastic elements that require use of JAGS....

Not run:
require(rjags)
following sets random seed, but note that under JAGS 3.4 many
models are still not fully repeatable (JAGS 4 should fix this)
jd$jags.ini$.RNG.name <- "base::Mersenne-Twister" ## setting RNG
jd$jags.ini$.RNG.seed <- 6 ## how to set RNG seed
jm <- jags.model(jags.file,data=jd$jags.data,init=jd$jags.ini,n.chains=1)
list.samplers(jm)
sam <- jags.samples(jm,c("b","rho","scale","mu"),n.iter=10000,thin=10)
jam <- sim2jam(sam,jd$pregam)
plot(jam,pages=1)
jam
pd <- data.frame(x0=c(.5,.6),x1=c(.4,.2),x2=c(.8,.4),x3=c(.1,.1))
fv <- predict(jam,newdata=pd)

End(Not run)

```

---

k.check

---

*Checking smooth basis dimension*

---

## Description

Takes a fitted gam object produced by `gam()` and runs diagnostic tests of whether the basis dimension choices are adequate.

**Usage**

```
k.check(b, subsample=5000, n.rep=400)
```

**Arguments**

|           |                                                                                   |
|-----------|-----------------------------------------------------------------------------------|
| b         | a fitted gam object as produced by <a href="#">gam()</a> .                        |
| subsample | above this number of data, testing uses a random sub-sample of data of this size. |
| n.rep     | how many re-shuffles to do to get p-value for k testing.                          |

**Details**

The test of whether the basis dimension for a smooth is adequate (Wood, 2017, section 5.9) is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the k-index reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The p-value is computed by simulation: the residuals are randomly re-shuffled n.rep times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than subsample data, the tests are based of subsample randomly sampled data. Low p-values may indicate that the basis dimension, k, has been set too low, especially if the reported edf is close to  $k'$ , the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated p-values will of course vary widely from one replicate to the next. Currently smooths of factor variables are not supported and will give an NA p-value.

Doubling a suspect k and re-fitting is sensible: if the reported edf increases substantially then you may have been missing something in the first fit. Of course p-values can be low for reasons other than a too low k. See [choose.k](#) for fuller discussion.

**Value**

A matrix containing the output of the tests described above.

**Examples**

```
library(mgcv)
set.seed(0)
dat <- gamSim(1,n=200)
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
plot(b,pages=1)
k.check(b)
```

ldetS

*Getting log generalized determinant of penalty matrices***Description**

INTERNAL function calculating the log generalized determinant of penalty matrix  $S$  stored block-wise in an  $Sl$  list (which is the output of  $Sl.setup$ ).

**Usage**

```
ldetS(Sl, rho, fixed, np, root = FALSE, Stot=FALSE, repara = TRUE,
 nt = 1, deriv=2, sparse=FALSE)
```

**Arguments**

|                     |                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Sl</code>     | the output of <code>Sl.setup</code> .                                                                                                                 |
| <code>rho</code>    | the log smoothing parameters.                                                                                                                         |
| <code>fixed</code>  | an array indicating whether the smoothing parameters are fixed (or free).                                                                             |
| <code>np</code>     | number of coefficients.                                                                                                                               |
| <code>root</code>   | indicates whether or not to return the matrix square root, $E$ , of the total penalty $S_{tot}$ .                                                     |
| <code>Stot</code>   | indicates whether or not to return the total penalty $S_{tot}$ .                                                                                      |
| <code>repara</code> | if TRUE multi-term blocks will be re-parameterized using <code>gam.reparam</code> , and a re-parameterization object supplied in the returned object. |
| <code>nt</code>     | number of parallel threads to use.                                                                                                                    |
| <code>deriv</code>  | order of derivative to use                                                                                                                            |
| <code>sparse</code> | should $E$ and/or $S$ be sparse?                                                                                                                      |

**Value**

A list containing:

- `ldetS`: the log-determinant of  $S$ .
- `ldetS1`: the gradient of the log-determinant of  $S$ .
- `ldetS2`: the Hessian of the log-determinant of  $S$ .
- `Sl`: with modified  $rS$  terms, if needed and  $\rho$  added to each block
- `rp`: a re-parameterization list.
- `E`: a total penalty square root such that  $t(E) \%*\% E = S_{tot}$  (if `root==TRUE`).
- `S`: the total penalty matrix (if `Stot==TRUE`).

ldTweedie

*Log Tweedie density evaluation***Description**

A function to evaluate the log of the Tweedie density for variance powers between 1 and 2, inclusive. Also evaluates first and second derivatives of log density w.r.t. its scale parameter, phi, and p, or w.r.t.  $\rho = \log(\phi)$  and theta where  $p = (a + b \cdot \exp(\theta)) / (1 + \exp(\theta))$ .

**Usage**

```
ldTweedie(y, mu=y, p=1.5, phi=1, rho=NA, theta=NA, a=1.001, b=1.999, all.derivs=FALSE)
```

**Arguments**

|            |                                                                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| y          | values at which to evaluate density.                                                                                                               |
| mu         | corresponding means (either of same length as y or a single value).                                                                                |
| p          | the variance of y is proportional to its mean to the power p. p must be between 1 and 2. 1 is Poisson like (exactly Poisson if phi=1), 2 is gamma. |
| phi        | The scale parameter. Variance of y is $\phi \cdot \mu^p$ .                                                                                         |
| rho        | optional log scale parameter. Over-rides phi if theta also supplied.                                                                               |
| theta      | parameter such that $p = (a + b \cdot \exp(\theta)) / (1 + \exp(\theta))$ . Over-rides p if rho also supplied.                                     |
| a          | lower limit parameter ( $>1$ ) used in definition of p from theta.                                                                                 |
| b          | upper limit parameter ( $<2$ ) used in definition of p from theta.                                                                                 |
| all.derivs | if TRUE then derivatives w.r.t. mu are also returned. Only available with rho and phi parameterization.                                            |

**Details**

A Tweedie random variable with  $1 < p < 2$  is a sum of N gamma random variables where N has a Poisson distribution. The  $p=1$  case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For  $1 < p < 2$  the distribution is supported on the positive reals with a point mass at zero.  $p=2$  is a gamma distribution. As p gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at  $p=1$ .

ldTweedie is based on the series evaluation method of Dunn and Smyth (2005). Without the restriction on p the calculation of Tweedie densities is less straightforward. If you really need this case then the tweedie package is the place to start.

The rho, theta parameterization is useful for optimization of p and phi, in order to keep p bounded well away from 1 and 2, and phi positive. The derivatives near  $p=1$  tend to infinity.

Note that if p and phi (or theta and rho) both contain only a single unique value, then the underlying code is able to use buffering to avoid repeated calls to expensive log gamma, di-gamma and tri-gamma functions (mu can still be a vector of different values). This is much faster than is possible when these parameters are vectors with different values.

**Value**

A matrix with 6 columns, or 10 if `all.derivs=TRUE`. The first is the log density of  $y$  (log probability if  $p=1$ ). The second and third are the first and second derivatives of the log density w.r.t.  $\phi$ . 4th and 5th columns are first and second derivative w.r.t.  $p$ , final column is second derivative w.r.t.  $\phi$  and  $p$ .

If  $\rho$  and  $\theta$  were supplied then derivatives are w.r.t. these. In this case, and if `all.derivs=TRUE` then the 7th column is the derivative w.r.t.  $\mu$ , the 8th is the 2nd derivative w.r.t.  $\mu$ , the 9th is the mixed derivative w.r.t.  $\theta$  and  $\mu$  and the 10th is the mixed derivative w.r.t.  $\rho$  and  $\mu$ .

linear.functional.terms

*Linear functionals of a smooth in GAMs*

---

**Description**

`gam` allows the response variable to depend on linear functionals of smooth terms. Specifically dependencies of the form

$$g(\mu_i) = \dots + \sum_j L_{ij} f(x_{ij}) + \dots$$

are allowed, where the  $x_{ij}$  are covariate values and the  $L_{ij}$  are fixed weights. i.e. the response can depend on the weighted sum of the same smooth evaluated at different covariate values. This allows, for example, for the response to depend on the derivatives or integrals of a smooth (approximated by finite differencing or quadrature, respectively). It also allows dependence on predictor functions (sometimes called ‘signal regression’).

The mechanism by which this is achieved is to supply matrices of covariate values to the model smooth terms specified by **s** or **te** terms in the model formula. Each column of the covariate matrix gives rise to a corresponding column of predictions from the smooth. Let the resulting matrix of evaluated smooth values be **F** (**F** will have the same dimension as the covariate matrices). In the absence of a by variable then these columns are simply summed and added to the linear predictor. i.e. the contribution of the term to the linear predictor is `rowSums(F)`. If a by variable is present then it must be a matrix, **L**, say, of the same dimension as **F** (and the covariate matrices), and it contains the weights  $L_{ij}$  in the summation given above. So in this case the contribution to the linear predictor is `rowSums(L*F)`.

Note that if a **L1** (i.e. `rowSums(L)`) is a constant vector, or there is no by variable then the smooth will automatically be centred in order to ensure identifiability. Otherwise it will not be. Note also that for centred smooths it can be worth replacing the constant term in the model with `rowSums(L)` in order to ensure that predictions are automatically on the right scale.

`predict.gam` can accept matrix predictors for prediction with such terms, in which case its `newdata` argument will need to be a list. However when predicting from the model it is not necessary to provide matrix covariate and by variable values. For example to simply examine the underlying smooth function one would use vectors of covariate values and vector by variables, with the by variable and equivalent of **L1**, above, set to vectors of ones.

The mechanism is usable with random effect smooths which take factor arguments, by using a trick to create a 2D array of factors. Simply create a factor vector containing the columns of the factor matrix stacked end to end (column major order). Then reset the dimensions of this vector to create the appropriate 2D array: the first dimension should be the number of response data and the second the number of columns of the required factor matrix. You can not use `matrix` or `data.matrix` to set up the required matrix of factor levels. See example below.

dim(fac) <- c(n,2)

simulate data from such a model...
nb <- length(levels(fac))
b <- rnorm(nb)
y <- 20*(x-.3)^4 + b[fac[,1]] - b[fac[,2]] + rnorm(n)*.5

L <- matrix(-1,n,2);L[,1] <- 1 ## the differencing 'by' variable

mod <- gam(y ~ s(x) + s(fac,by=L,bs="re"),method="REML")
gam.vcomp(mod)
plot(mod,page=1)

example of prediction using matrices...
dat <- list(L=L[1:20,],fac=fac[1:20,],x=x[1:20],y=y[1:20])
predict(mod,newdata=dat)

#####
multivariate integral example. Function 'test1' will be integrated#
(by midpoint quadrature) over 100 equal area sub-squares covering
the unit square. Noise is added to the resulting simulated data.
'test1' is estimated from the resulting data using two alternative#
smooths.
#####

test1 <- function(x,z,sx=0.3,sz=0.4)
{ (pi*sx*sz)*(1.2*exp(-(x-0.2)^2/sx^2-(z-0.3)^2/sz^2)+
 0.8*exp(-(x-0.7)^2/sx^2-(z-0.8)^2/sz^2))
}

create quadrature (integration) grid, in useful order
ig <- 5 ## integration grid within square

```

```

mx <- mz <- (1:ig-.5)/ig
ix <- rep(mx,ig); iz <- rep(mz,rep(ig,ig))

og <- 10 ## observarion grid
mx <- mz <- (1:og-1)/og
ox <- rep(mx,og); ox <- rep(ox,rep(ig^2,og^2))
oz <- rep(mz,rep(og,og)); oz <- rep(oz,rep(ig^2,og^2))

x <- ox + ix/og; z <- oz + iz/og ## full grid, subsquare by subsquare

create matrix covariates...
X <- matrix(x,og^2,ig^2,byrow=TRUE)
Z <- matrix(z,og^2,ig^2,byrow=TRUE)

create simulated test data...
dA <- 1/(og*ig)^2 ## quadrature square area
F <- test1(X,Z) ## evaluate on grid
f <- rowSums(F)*dA ## integrate by midpoint quadrature
y <- f + rnorm(og^2)*5e-4 ## add noise
... so each y is a noisy observation of the integral of `test1'
over a 0.1 by 0.1 sub-square from the unit square

Now fit model to simulated data...

L <- X*0 + dA

... let F be the matrix of the smooth evaluated at the x,z values
in matrices X and Z. rowSums(L*F) gives the model predicted
integrals of `test1' corresponding to the observed `y'

L1 <- rowSums(L) ## smooths are centred --- need to add in L%*%1

fit models to reconstruct `test1'....

b <- gam(y~s(X,Z,by=L)+L1-1) ## (L1 and const are confounded here)
b1 <- gam(y~te(X,Z,by=L)+L1-1) ## tensor product alternative

plot results...

old.par<-par(mfrow=c(2,2))
x<-runif(n); z<-runif(n);
xs<-seq(0,1,length=30); zs<-seq(0,1,length=30)
pr<-data.frame(x=rep(xs,30), z=rep(zs,rep(30,30)))
truth<-matrix(test1(prx,prz),30,30)
contour(xs,zs,truth)
plot(b)
vis.gam(b,view=c("X","Z"),cond=list(L1=1,L=1),plot.type="contour")
vis.gam(b1,view=c("X","Z"),cond=list(L1=1,L=1),plot.type="contour")

#####
A "signal" regression example...#
#####

rf <- function(x=seq(0,1,length=100)) {
 ## generates random functions...
 m <- ceiling(runif(1)*5) ## number of components
 f <- x*0;

```

```

mu <- runif(m,min(x),max(x));sig <- (runif(m)+.5)*(max(x)-min(x))/10
for (i in 1:m) f <- f+ dnorm(x,mu[i],sig[i])
f
}

x <- seq(0,1,length=100) ## evaluation points

example functional predictors...
par(mfrow=c(3,3));for (i in 1:9) plot(x,rf(x),type="l",xlab="x")

simulate 200 functions and store in rows of L...
L <- matrix(NA,200,100)
for (i in 1:200) L[i,] <- rf() ## simulate the functional predictors

f2 <- function(x) { ## the coefficient function
 (0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10)/10
}

f <- f2(x) ## the true coefficient function

y <- L%*%f + rnorm(200)*20 ## simulated response data

Now fit the model E(y) = L%*%f(x) where f is a smooth function.
The summation convention is used to evaluate smooth at each value
in matrix X to get matrix F, say. Then rowSum(L*F) gives E(y).

create matrix of eval points for each function. Note that
`smoothCon' is smart and will recognize the duplication...
X <- matrix(x,200,100,byrow=TRUE)

b <- gam(y~s(X,by=L,k=20))
par(mfrow=c(1,1))
plot(b,shade=TRUE);lines(x,f,col=2)

```

logLik.gam

*AIC and Log likelihood for a fitted GAM***Description**

Function to extract the log-likelihood for a fitted gam model (note that the models are usually fitted by penalized likelihood maximization). Used by [AIC](#). See details for more information on AIC computation.

**Usage**

```
S3 method for class 'gam'
logLik(object,...)
```

**Arguments**

|        |                                                         |
|--------|---------------------------------------------------------|
| object | fitted model objects of class gam as produced by gam(). |
| ...    | un-used in this case                                    |

## Details

Modification of `logLik.glm` which corrects the degrees of freedom for use with `gam` objects.

The function is provided so that [AIC](#) functions correctly with `gam` objects, and uses the appropriate degrees of freedom (accounting for penalization). See e.g. Wood, Pya and Saefken (2016) for a derivation of an appropriate AIC.

For [gaussian](#) family models the MLE of the scale parameter is used. For other families with a scale parameter the estimated scale parameter is used. This is usually not exactly the MLE, and is not the simple deviance based estimator used with [glm](#) models. This is because the simple deviance based estimator can be badly biased in some cases, for example when a Tweedie distribution is employed with low count data.

There are two possible AIC's that might be considered for use with GAMs. Marginal AIC is based on the marginal likelihood of the GAM, that is the likelihood based on treating penalized (e.g. spline) coefficients as random and integrating them out. The degrees of freedom is then the number of smoothing/variance parameters + the number of fixed effects. The problem with Marginal AIC is that marginal likelihood underestimates variance components/oversmooths, so that the approach favours simpler models excessively (substituting REML does not work, because REML is not comparable between models with different unpenalized/fixed components). Conditional AIC uses the likelihood of all the model coefficients, evaluated at the penalized MLE. The degrees of freedom to use then is the effective degrees of freedom for the model. However, Greven and Kneib (2010) show that the neglect of smoothing parameter uncertainty can lead to this conditional AIC being excessively likely to select larger models. Wood, Pya and Saefken (2016) propose a simple correction to the effective degrees of freedom to fix this problem. `mgcv` applies this correction whenever possible: that is when using ML or REML smoothing parameter selection with [gam](#) or [bam](#). The correction is not computable when using the Extended Fellner Schall or BFGS optimizer (since the correction requires an estimate of the covariance matrix of the log smoothing parameters).

## Value

Standard `logLik` object: see [logLik](#).

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)> based directly on `logLik.glm`

[AIC](#)

lp

*Basic linear programming***Description**

Solves, for  $\mathbf{x}$ , linear programming problems in the standard form

$$\min \mathbf{c}^T \mathbf{x} \text{ s.t. } \mathbf{A}\mathbf{x} = \mathbf{b}, \mathbf{b} \geq \mathbf{0}$$

or in the form

$$\min \mathbf{c}^T \mathbf{x} \text{ s.t. } \mathbf{A}\mathbf{x} \geq \mathbf{b}, \mathbf{C}\mathbf{x} = \mathbf{d}$$

A lightweight implementation of the simplex method, designed for problems of modest size, not large scale problems requiring sparse methods.

`feasible` finds starting values meeting the constraints, which is also useful for finding feasible initial values for quadratic programming.

**Usage**

```
lp(c,A,b,C=NULL,d=NULL,Bi=NULL,maxit=max(1000, nrow(A) * 10), phase1 = FALSE)
feasible(A,b,C=NULL,d=NULL,maxit = max(1000, nrow(A) * 10))
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>c</code>      | The vector defining the linear program objective function $\mathbf{c}^T \mathbf{x}$ .                                                                                                                                                                                                        |
| <code>A</code>      | The constraint matrix.                                                                                                                                                                                                                                                                       |
| <code>b</code>      | The vector defining the r.h.s. of the constraint involving <code>A</code> .                                                                                                                                                                                                                  |
| <code>C</code>      | NULL to signal a problem in standard form. Otherwise the matrix defining the equality constraints.                                                                                                                                                                                           |
| <code>d</code>      | NULL to signal a problem in standard form. Otherwise the vector defining the r.h.s. of the equality constraint.                                                                                                                                                                              |
| <code>Bi</code>     | For a problem in standard form, index of the elements of $\mathbf{x}$ initially non-zero. $\mathbf{A}[:, Bi] \mathbf{x}^* = \mathbf{b}$ must have a unique solution with $\mathbf{x}^* \geq \mathbf{0}$ . NULL to have this set found automatically by solution of a phase 1 linear program. |
| <code>maxit</code>  | Maximum number of iterations of the simplex method to allow.                                                                                                                                                                                                                                 |
| <code>phase1</code> | signals that function is being called to solve a phase 1 problem.                                                                                                                                                                                                                            |

**Details**

This code was written to provide a lightweight method for finding feasible initial coefficients for shape constrained splines, but is suitable for solving general linear programming problems of modest size. Given that it uses dense matrix computations, it is not suitable for large scale problems where it is important to exploit sparsity. Neither is it suitable for the sort of linear programming problems arising from integer programs, where degeneracy may be a substantial problem.

The function uses the simplex method (see e.g. Chapter 13 of Nocedal and Wright, 2006). Computational efficiency is ensured by QR decomposing  $\mathbf{A}[:, Bi]$  and then efficiently updating the decomposition, every time the active set `Bi` changes, using Givens based updating schemes broadly similar to those given in Golub and van Loan (2013) 5.1.3 p240 and 6.5.3 p337. Given the QR factorization solution of systems involving  $\mathbf{A}[:, Bi]$  is efficient.

**Value**

A vector. Either the solution of the problem (lp), or a feasible initial vector (feasible). Produces an error if there is no solution or maxit is exceeded.

**WARNINGS**

Not designed for large scale problems requiring sparse methods, nor for problems where significant degeneracy is expected.

**Examples**

```
library(mgcv)
very simple linear program...
c <- c(-4,-2,0,0)
A <- matrix(c(1,2,1,.5,1,0,0,1),2,4)
b <- c(5,8)
x <- lp(c,A,b,c(3,4));sum(c*x);x ## Bi given

x <- lp(c,A,b);sum(c*x);x ## Bi found automatically

equivalent formulation Ax>b
A <- -matrix(c(1,2,1,.5),2,2)
b <- -c(5,8)
C <- matrix(0,0,2); d <- numeric(0)
c <- c(-4,-2)
x <- lp(c,A,b,C=C,d=d);sum(c*x);x

equivalent formulation Ax>b, Cx=d
c <- c(-4,-2,0)
A <- matrix(c(0,-2,0,-.5,1,0),2,3)
C <- matrix(c(1,1,1),1,3); d <- 5
b <- c(0,-8)
x <- lp(c,A,b,C=C,d=d);sum(c*x);x
```

|         |                              |
|---------|------------------------------|
| ls.size | <i>Size of list elements</i> |
|---------|------------------------------|

---

**Description**

Produces a named array giving the size, in bytes, of the elements of a list.

**Usage**

```
ls.size(x)
```

**Arguments**

x                      A list.

**Value**

A numeric vector giving the size in bytes of each element of the list x. The elements of the array have the same names as the elements of the list. If x is not a list then its size in bytes is returned, un-named.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

```
library(mgcv)
b <- list(M=matrix(runif(100),10,10),quote=
"The world is ruled by idiots because only an idiot would want to rule the world.",
fam=binomial())
ls.size(b)
```

|       |                                                                      |
|-------|----------------------------------------------------------------------|
| magic | <i>Stable Multiple Smoothing Parameter Estimation by GCV or UBRE</i> |
|-------|----------------------------------------------------------------------|

---

**Description**

Function to efficiently estimate smoothing parameters in generalized ridge regression problems with multiple (quadratic) penalties, by GCV or UBRE. The function uses Newton's method in multi-dimensions, backed up by steepest descent to iteratively adjust the smoothing parameters for each penalty (one penalty may have a smoothing parameter fixed at 1).

For maximal numerical stability the method is based on orthogonal decomposition methods, and attempts to deal with numerical rank deficiency gracefully using a truncated singular value decomposition approach.

**Usage**

```
magic(y,X,sp,S,off,L=NULL,lsp0=NULL,rank=NULL,H=NULL,C=NULL,
 w=NULL,gamma=1,scale=1,gcv=TRUE,ridge.parameter=NULL,
 control=list(tol=1e-6,step.half=25,rank.tol=
 .Machine$double.eps^0.5),extra.rss=0,n.score=length(y),nthreads=1)
```

**Arguments**

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>               | is the response data vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>X</code>               | is the model matrix (more columns than rows are allowed).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>sp</code>              | is the array of smoothing parameters. The vector $L\%*\log(sp) + 1sp0$ contains the logs of the smoothing parameters that actually multiply the penalty matrices stored in <code>S</code> ( <code>L</code> is taken as the identity if <code>NULL</code> ). Any <code>sp</code> values that are negative are autoinitialized, otherwise they are taken as supplying starting values. A supplied starting value will be reset to a default starting value if the gradient of the GCV/UBRE score is too small at the supplied value. |
| <code>S</code>               | is a list of of penalty matrices. <code>S[[i]]</code> is the <i>i</i> th penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of <code>S[[i]]</code> occupies element <code>off[i]</code> , <code>off[i]</code> of the <i>i</i> th penalty matrix. Each <code>S[[i]]</code> must be positive semi-definite. Set to <code>list()</code> if there are no smoothing parameters to be estimated.           |
| <code>off</code>             | is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving <code>S[[i]]</code> .                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>L</code>               | is a matrix mapping $\log(sp)$ to the log smoothing parameters that actually multiply the penalties defined by the elements of <code>S</code> . Taken as the identity, if <code>NULL</code> . See above under <code>sp</code> .                                                                                                                                                                                                                                                                                                    |
| <code>1sp0</code>            | If <code>L</code> is not <code>NULL</code> this is a vector of constants in the linear transformation from $\log(sp)$ to the actual log smoothing parameters. So the logs of the smoothing parameters multiplying the <code>S[[i]]</code> are given by $L\%*\log(sp) + 1sp0$ . Taken as 0 if <code>NULL</code> .                                                                                                                                                                                                                   |
| <code>rank</code>            | is an array specifying the ranks of the penalties. This is useful, but not essential, for forming square roots of the penalty matrices.                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>H</code>               | is the optional offset penalty - i.e. a penalty with a smoothing parameter fixed at 1. This is useful for allowing regularization of the estimation process, fixed smoothing penalties etc.                                                                                                                                                                                                                                                                                                                                        |
| <code>C</code>               | is the optional matrix specifying any linear equality constraints on the fitting problem. If <code>b</code> is the parameter vector then the parameters are forced to satisfy $Cb = 0$ .                                                                                                                                                                                                                                                                                                                                           |
| <code>w</code>               | the regression weights. If this is a matrix then it is taken as being the square root of the inverse of the covariance matrix of <code>y</code> , specifically $V_y^{-1} = w'w$ . If <code>w</code> is an array then it is taken as the diagonal of this matrix, or simply the weight for each element of <code>y</code> . See below for an example using this.                                                                                                                                                                    |
| <code>gamma</code>           | is an inflation factor for the model degrees of freedom in the GCV or UBRE score.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>scale</code>           | is the scale parameter for use with UBRE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>gcv</code>             | should be set to <code>TRUE</code> if GCV is to be used, <code>FALSE</code> for UBRE.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>ridge.parameter</code> | It is sometimes useful to apply a ridge penalty to the fitting problem, penalizing the parameters in the constrained space directly. Setting this parameter to a value greater than zero will cause such a penalty to be used, with the magnitude given by the parameter value.                                                                                                                                                                                                                                                    |
| <code>control</code>         | is a list of iteration control constants with the following elements:<br><b>tol</b> The tolerance to use in judging convergence.                                                                                                                                                                                                                                                                                                                                                                                                   |

|                        |                                                                                                                                                                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | <b>step.half</b> If a trial step fails then the method tries halving it up to a maximum of <code>step.half</code> times.                                                                                                                                            |
|                        | <b>rank.tol</b> is a constant used to test for numerical rank deficiency of the problem. Basically any singular value less than <code>rank_tol</code> multiplied by the largest singular value of the problem is set to zero.                                       |
| <code>extra.rss</code> | is a constant to be added to the residual sum of squares (squared norm) term in the calculation of the GCV, UBRE and scale parameter estimate. In conjunction with <code>n.score</code> , this is useful for certain methods for dealing with very large data sets. |
| <code>n.score</code>   | number to use as the number of data in GCV/UBRE score calculation: usually the actual number of data, but there are methods for dealing with very large datasets that change this.                                                                                  |
| <code>nthreads</code>  | <code>magic</code> can make use of multiple threads if this is set to <code>&gt;1</code> .                                                                                                                                                                          |

## Details

The method is a computationally efficient means of applying GCV or UBRE (often approximately AIC) to the problem of smoothing parameter selection in generalized ridge regression problems of the form:

$$\text{minimise } \|\mathbf{W}(\mathbf{X}\mathbf{b} - \mathbf{y})\|^2 + \mathbf{b}'\mathbf{H}\mathbf{b} + \sum_{i=1}^m \theta_i \mathbf{b}'\mathbf{S}_i\mathbf{b}$$

possibly subject to constraints  $\mathbf{C}\mathbf{b} = \mathbf{0}$ .  $\mathbf{X}$  is a design matrix,  $\mathbf{b}$  a parameter vector,  $\mathbf{y}$  a data vector,  $\mathbf{W}$  a weight matrix,  $\mathbf{S}_i$  a positive semi-definite matrix of coefficients defining the  $i$ th penalty with associated smoothing parameter  $\theta_i$ ,  $\mathbf{H}$  is the positive semi-definite offset penalty matrix and  $\mathbf{C}$  a matrix of coefficients defining any linear equality constraints on the problem.  $\mathbf{X}$  need not be of full column rank.

The  $\theta_i$  are chosen to minimize either the GCV score:

$$V_g = \frac{n\|\mathbf{W}(\mathbf{y} - \mathbf{A}\mathbf{y})\|^2}{[\text{tr}(\mathbf{I} - \gamma\mathbf{A})]^2}$$

or the UBRE score:

$$V_u = \|\mathbf{W}(\mathbf{y} - \mathbf{A}\mathbf{y})\|^2/n - 2\phi\text{tr}(\mathbf{I} - \gamma\mathbf{A})/n + \phi$$

where  $\gamma$  is gamma the inflation factor for degrees of freedom (usually set to 1) and  $\phi$  is scale, the scale parameter.  $\mathbf{A}$  is the hat matrix (influence matrix) for the fitting problem (i.e the matrix mapping data to fitted values). Dependence of the scores on the smoothing parameters is through  $\mathbf{A}$ .

The method operates by Newton or steepest descent updates of the logs of the  $\theta_i$ . A key aspect of the method is stable and economical calculation of the first and second derivatives of the scores w.r.t. the log smoothing parameters. Because the GCV/UBRE scores are flat w.r.t. very large or very small  $\theta_i$ , it's important to get good starting parameters, and to be careful not to step into a flat region of the smoothing parameter space. For this reason the algorithm rescales any Newton step that would result in a  $\log(\theta_i)$  change of more than 5. Newton steps are only used if the Hessian of the GCV/UBRE is positive definite, otherwise steepest descent is used. Similarly steepest descent is used if the Newton step has to be contracted too far (indicating that the quadratic model underlying Newton is poor). All initial steepest descent steps are scaled so that their largest component is 1. However a step is calculated, it is never expanded if it is successful (to avoid flat portions of the objective), but steps are successively halved if they do not decrease the GCV/UBRE score, until

they do, or the direction is deemed to have failed. (Given the smoothing parameters the optimal **b** parameters are easily found.)

The method is coded in C with matrix factorizations performed using LINPACK and LAPACK routines.

## Value

The function returns a list with the following items:

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>b</b>        | The best fit parameters given the estimated smoothing parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>scale</b>    | the estimated (GCV) or supplied (UBRE) scale parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>score</b>    | the minimized GCV or UBRE score.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>sp</b>       | an array of the estimated smoothing parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>sp.full</b>  | an array of the smoothing parameters that actually multiply the elements of <b>S</b> (same as <b>sp</b> if <b>L</b> was <b>NULL</b> ). This is $\exp(L\%*\log(sp))$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>rV</b>       | a factored form of the parameter covariance matrix. The (Bayesian) covariance matrix of the parameters <b>b</b> is given by $rV\%*t(rV)*scale$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>gcv.info</b> | is a list of information about the performance of the method with the following elements:<br><b>full.rank</b> The apparent rank of the problem: number of parameters less number of equality constraints.<br><b>rank</b> The estimated actual rank of the problem (at the final iteration of the method).<br><b>fully.converged</b> is <b>TRUE</b> if the method converged by satisfying the convergence criteria, and <b>FALSE</b> if it covered by failing to decrease the score along the search direction.<br><b>hess.pos.def</b> is <b>TRUE</b> if the hessian of the UBRE or GCV score was positive definite at convergence.<br><b>iter</b> is the number of Newton/Steepest descent iterations taken.<br><b>score.calls</b> is the number of times that the GCV/UBRE score had to be evaluated.<br><b>rms.grad</b> is the root mean square of the gradient of the UBRE/GCV score w.r.t. the smoothing parameters.<br><b>R</b> The factor <b>R</b> from the QR decomposition of the weighted model matrix. This is un-pivoted so that column order corresponds to <b>X</b> . So it may not be upper triangular. |

Note that some further useful quantities can be obtained using [magic.post.proc](#).

## Examples

```
Use 'magic' for a standard additive model fit ...
library(mgcv)
set.seed(1); n <- 200; sig <- 1
dat <- gamSim(1, n=n, scale=sig)
k <- 30
set up additive model
G <- gam(y~s(x0,k=k)+s(x1,k=k)+s(x2,k=k)+s(x3,k=k), fit=FALSE, data=dat)
fit using magic (and gam default tolerance)
mgfit <- magic(Gy, GX, Gsp, GS, G$off, rank=G$rank,
 control=list(tol=1e-7, step.half=15))
and fit using gam as consistency check
b <- gam(G=G)
mgfit$sp; b$sp # compare smoothing parameter estimates
edf <- magic.post.proc(G$X, mgfit, G$w)$edf # get e.d.f. per param
range(edf-b$edf) # compare

p>n example... fit model to first 100 data only, so more
params than data...

mgfit <- magic(G$y[1:100], G$X[1:100,], Gsp, GS, G$off, rank=G$rank)
edf <- magic.post.proc(G$X[1:100,], mgfit, G$w[1:100])$edf

constrain first two smooths to have identical smoothing parameters
L <- diag(3); L <- rbind(L[1,], L)
mgfit <- magic(Gy, GX, rep(-1, 3), GS, Goff, L=L, rank=G$rank, C=G$C)

Now a correlated data example ...
library(nlme)
simulate truth
set.seed(1); n <- 400; sig <- 2
x <- 0:(n-1)/(n-1)
f <- 0.2*x^11*(10*(1-x))^6 + 10*(10*x)^3*(1-x)^10
produce scaled covariance matrix for AR1 errors...
V <- corMatrix(Initialize(corAR1(.6), data.frame(x=x)))
Cv <- chol(V) # t(Cv)%*%Cv=V
Simulate AR1 errors ...
e <- t(Cv)%*%rnorm(n, 0, sig) # so cov(e) = V * sig^2
Observe truth + AR1 errors
y <- f + e
GAM ignoring correlation
par(mfrow=c(1,2))
b <- gam(y~s(x, k=20))
plot(b); lines(x, f - mean(f), col=2); title("Ignoring correlation")
Fit smooth, taking account of *known* correlation...
w <- solve(t(Cv)) # V^{-1} = w'w
Use 'gam' to set up model for fitting...
G <- gam(y~s(x, k=20), fit=FALSE)
fit using magic, with weight *matrix*
mgfit <- magic(Gy, GX, Gsp, GS, G$off, rank=G$rank, C=G$C, w=w)
Modify previous gam object using new fit, for plotting...
mg.stuff <- magic.post.proc(G$X, mgfit, w)
b$edf <- mg.stuff$edf; b$Vp <- mg.stuff$Vb
b$coefficients <- mgfit$b
plot(b); lines(x, f - mean(f), col=2); title("Known correlation")
```

magic.post.proc

*Auxilliary information from magic fit***Description**

Obtains Bayesian parameter covariance matrix, frequentist parameter estimator covariance matrix, estimated degrees of freedom for each parameter and leading diagonal of influence/hat matrix, for a penalized regression estimated by magic.

**Usage**

```
magic.post.proc(X,object,w=NULL)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X      | is the model matrix.                                                                                                                                                                                                                                                                                                                                                          |
| object | is the list returned by magic after fitting the model with model matrix X.                                                                                                                                                                                                                                                                                                    |
| w      | is the weight vector used in fitting, or the weight matrix used in fitting (i.e. supplied to magic, if one was.). If w is a vector then its elements are typically proportional to reciprocal variances (but could even be negative). If w is a matrix then $t(w) \% \% w$ should typically give the inverse of the covariance matrix of the response data supplied to magic. |

**Details**

object contains  $rV$  ( $V$ , say), and scale ( $\phi$ , say) which can be used to obtain the require quantities as follows. The Bayesian covariance matrix of the parameters is  $VV'\phi$ . The vector of estimated degrees of freedom for each parameter is the leading diagonal of  $VV'X'W'WX$  where  $W$  is either the weight matrix w or the matrix  $\text{diag}(w)$ . The hat/influence matrix is given by  $WXVV'X'W'$ .

The frequentist parameter estimator covariance matrix is  $VV'X'W'WXVV'\phi$ : it is sometimes useful for testing terms for equality to zero.

**Value**

A list with three items:

|     |                                                                                   |
|-----|-----------------------------------------------------------------------------------|
| Vb  | the Bayesian covariance matrix of the model parameters.                           |
| Ve  | the frequentist covariance matrix for the parameter estimators.                   |
| hat | the leading diagonal of the hat (influence) matrix.                               |
| edf | the array giving the estimated degrees of freedom associated with each parameter. |

|       |                             |
|-------|-----------------------------|
| mchol | <i>Sparse chol function</i> |
|-------|-----------------------------|

---

## Description

A wrapper for the Cholesky function from the *Matrix* package that produces the sparse pivoted Cholesky factor of a positive definite matrix, and returns the pivot vector for this as an attribute. The *Matrix* package `chol` function no longer returns the pivots.

## Usage

```
mchol(A)
```

## Arguments

|   |                                                                                           |
|---|-------------------------------------------------------------------------------------------|
| A | A sparse matrix suitable for passing to Cholesky function from the <i>Matrix</i> package. |
|---|-------------------------------------------------------------------------------------------|

## Details

The *Matrix* version of `chol` performs sparse Cholesky decomposition with sparsity maintaining pivoting, but no longer returns the pivot vector, rendering the returned factor useless for many purposes. This wrapper function simply fixes this. It also ensures that there are no numerical zeroes below the leading diagonal (not the default behaviour of `expand1`, which can put some numerical zeroes there, in place of structural ones, at least at version 1.6-5). Calls `chol(A, pivot=TRUE)` if A inherits from class `matrix`.

## Value

If A is positive definite then the upper triangular Cholesky factor matrix, with "pivot" attribute and "rank" attribute which is the dimension of A. Otherwise -1 with "rank" attribute -1.

## Examples

```
library(mgcv)
A sparse +ve def matrix
u <- sample(1:100,10)*.001
x <- i <- j <- 1:10
ii <- sample(1:10,10,replace=TRUE);
jj <- sample(1:10,10,replace=TRUE)
x <- c(x,u,u);
i <- c(i,ii,jj)
j <- c(j,jj,ii)
A <- Matrix::sparseMatrix(i=i,j=j,x=x)
R <- mchol(A)
piv <- attr(R,"pivot")
range(crossprod(R)-A[piv,piv])

i <- sample(1:5,10,replace=TRUE)
```

```
j <- sample(1:10,10,replace=TRUE)
u <- sample(1:100,10)*.001
A <- crossprod(Matrix::sparseMatrix(i=j,j=x,x=u))
mchol(A)
```

## Description

This page provides answers to some of the questions that get asked most often about mgcv

## FAQ list

1. **How can I compare gamm models?** In the identity link normal errors case, then AIC and hypothesis testing based methods are fine. Otherwise it is best to work out a strategy based on the [summary.gam](#). Alternatively, simple random effects can be fitted with [gam](#), which makes comparison straightforward. Package gamm4 is an alternative, which allows AIC type model selection for generalized models.
2. **How do I get the equation of an estimated smooth?** This slightly misses the point of semi-parametric modelling: the idea is that we estimate the form of the function from data without assuming that it has a particular simple functional form. Of course for practical computation the functions do have underlying mathematical representations, but they are not very helpful, when written down. If you do need the functional forms then see chapter 5 of Wood (2017). However for most purposes it is better to use [predict.gam](#) to evaluate the function for whatever argument values you need. If derivatives are required then the simplest approach is to use finite differencing (which also allows SEs etc to be calculated).
3. **Some of my smooths are estimated to be straight lines and their confidence intervals vanish at some point in the middle. What is wrong?** Nothing. Smooths are subject to sum-to-zero identifiability constraints. If a smooth is estimated to be a straight line then it consequently has one degree of freedom, and there is no choice about where it passes through zero — so the CI must vanish at that point.
4. **How do I test whether a smooth is significantly different from a straight line.** See [tprs](#) and the example therein.
5. **An example from an mgcv helpfile gives an error - is this a bug?** It might be, but first please check that the version of mgcv you have loaded into R corresponds to the version from which the helpfile came. Many such problems are caused by trying to run code only supported in a later mgcv version in an earlier version. Another possibility is that you have an object loaded whose name clashes with an mgcv function (for example you are trying to use the mgcv multinom function, but have another object called multinom loaded.)
6. **Some code from Wood (2006) causes an error: why?** The book was written using mgcv version 1.3. To allow for REML estimation of smoothing parameters in versions 1.5, some changes had to be made to the syntax. In particular the function gam.method no longer exists. The smoothness selection method (GCV, REML etc) is now controlled by the method argument to gam while the optimizer is selected using the optimizer argument. See [gam](#) for details.

7. **Why is a model object saved under a previous mgcv version not usable with the current mgcv version?** I'm sorry about this issue, I know it's really annoying. Here's my defence. Each mgcv version is run through an extensive test suite before release, to ensure that it gives the same results as before, unless there are good statistical reasons why not (e.g. improvements to p-value approximation, fixing of an error). However it is sometimes necessary to modify the internal structure of model objects in a way that makes an old style object unusable with a newer version. For example, bug fixes or new R features sometimes require changes in the way that things are computed which in turn require modification of the object structure. Similarly improvements, such as the ability to compute smoothing parameters by RE/ML require object level changes. The only fix to this problem is to access the old object using the original mgcv version (available on CRAN), or to recompute the fit using the current mgcv version.
8. **When using gamm or gamm4, the reported AIC is different for the gam object and the lme or lmer object. Why is this?** There are several reasons for this. The most important is that the models being used are actually different in the two representations. When treating the GAM as a mixed model, you are implicitly assuming that if you gathered a replicate dataset, the smooths in your model would look completely different to the smooths from the original model, except for having the same degree of smoothness. Technically you would expect the smooths to be drawn afresh from their distribution under the random effects model. When viewing the gam from the usual penalized regression perspective, you would expect smooths to look broadly similar under replication of the data. i.e. you are really using Bayesian model for the smooths, rather than a random effects model (it's just that the frequentist random effects and Bayesian computations happen to coincide for computing the estimates). As a result of the different assumptions about the data generating process, AIC model comparisons can give rather different answers depending on the model adopted. Which you use should depend on which model you really think is appropriate. In addition the computations of the AICs are different. The mixed model AIC uses the marginal likelihood and the corresponding number of model parameters. The gam model uses the penalized likelihood and the effective degrees of freedom.
9. **What does 'mgcv' stand for?** 'Mixed GAM Computation Vehicle', is my current best effort (let me know if you can do better). Originally it stood for 'Multiple GCV', which has long since ceased to be usefully descriptive, (and I can't really change 'mgcv' now without causing disruption). On a bad inbox day 'Mad GAM Computing Vulture'.
10. **My new method is failing to beat mgcv, what can I do?** If speed is the problem, then make sure that you use the slowest basis possible ("tp") with a large sample size, and experiment with different optimizers to find one that is slow for your problem. For prediction error/MSE, then leaving the smoothing basis dimensions at their arbitrary defaults, when these are inappropriate for the problem setting, is a good way of reducing performance. Similarly, using p-splines in place of derivative penalty based splines will often shave a little more from the performance here. Unlike REML/ML, prediction error based smoothness selection criteria such as Mallows Cp and GCV often produce a small proportion of severe overfits, so careful choice of smoothness selection method can help further. In particular GCV etc. usually result in worse confidence interval and p-value performance than ML or REML. If all this fails, try using a really odd simulation setup for which mgcv is clearly not suited: for example poor performance is almost guaranteed for small noisy datasets with large numbers of predictors.

mgcv.package

Mixed GAM Computation Vehicle with GCV/AIC/REML/NCV smoothness estimation and GAMMs by REML/PQL

---

## Description

mgcv provides functions for generalized additive modelling ([gam](#) and [bam](#)) and generalized additive mixed modelling ([gamm](#), and [random.effects](#)), including location scale and shape extensions. Shape constrained models can be estimated using [scasm](#). The term GAM is taken to include any model dependent on unknown smooth functions of predictors and estimated by quadratically penalized (possibly quasi-) likelihood maximization. Available distributions are covered in [family.mgcv](#) and available smooths in [smooth.terms](#).

Particular features of the package are facilities for automatic smoothness selection (Wood, 2004, 2011), and the provision of a variety of smooths of more than one variable. User defined smooths can be added. A Bayesian approach to confidence/credible interval calculation is provided. Linear functionals of smooths, penalization of parametric model terms and linkage of smoothing parameters are all supported. Lower level routines for generalized ridge regression and penalized linearly constrained least squares are also available. In addition to the main modelling functions, [jagam](#) provided facilities to ease the set up of models for use with JAGS, while [ginla](#) provides marginal inference via a version of Integrated Nested Laplace Approximation.

## Details

mgcv provides generalized additive modelling functions [gam](#), [predict.gam](#) and [plot.gam](#), which are very similar in use to the S functions of the same name designed by Trevor Hastie (with some extensions). However the underlying representation and estimation of the models is based on a penalized regression spline approach, with automatic smoothness selection. A number of other functions such as [summary.gam](#) and [anova.gam](#) are also provided, for extracting information from a fitted [gamObject](#).

Use of [gam](#) is much like use of [glm](#), except that within a gam model formula, isotropic smooths of any number of predictors can be specified using [s](#) terms, while scale invariant smooths of any number of predictors can be specified using [te](#), [ti](#) or [t2](#) terms. [smooth.terms](#) provides an overview of the built in smooth classes, and [random.effects](#) should be referred to for an overview of random effects terms (see also [mrf](#) for Markov random fields). Estimation is by penalized likelihood or quasi-likelihood maximization, with smoothness selection by GCV, GACV, gAIC/UBRE, [NCV](#) or (RE)ML. See [gam](#), [gam.models](#), [linear.functional.terms](#) and [gam.selection](#) for some discussion of model specification and selection. For detailed control of fitting see [gam.convergence](#), [gam](#) arguments method and optimizer and [gam.control](#). For checking and visualization see [gam.check](#), [choose.k](#), [vis.gam](#) and [plot.gam](#). While a number of types of smoother are built into the package, it is also extendable with user defined smooths, see [smooth.construct](#), for example.

A Bayesian approach to smooth modelling is used to derive standard errors on predictions, and hence credible intervals (see Marra and Wood, 2012). The Bayesian covariance matrix for the model coefficients is returned in [Vp](#) of the [gamObject](#). See [predict.gam](#) for examples of how this

can be used to obtain credible regions for any quantity derived from the fitted model, either directly, or by direct simulation from the posterior distribution of the model coefficients. Approximate p-values can also be obtained for testing individual smooth terms for equality to the zero function, using similar ideas (see Wood, 2013a,b). Frequentist approximations can be used for hypothesis testing based model comparison. See [anova.gam](#) and [summary.gam](#) for more on hypothesis testing.

For large datasets (that is large  $n$ ) see [bam](#) which is a version of [gam](#) with a much reduced memory footprint. `bam(..., discrete=TRUE)` offers the very efficient methods of Wood et al. (2017) and Li and Wood (2020).

The package also provides a generalized additive mixed modelling function, [gamm](#), based on a PQL approach and `lme` from the `nlme` library (for an `lme4` based version, see package `gamm4`). [gamm](#) is particularly useful for modelling correlated data (i.e. where a simple independence model for the residual variation is inappropriate). See [random.effects](#) for including random effects in models estimated by `gam`, `bam` or `scasm`.

In addition, low level routine [magic](#) can fit models to data with a known correlation structure.

Some underlying GAM fitting methods are available as low level fitting functions: see [magic](#). But there is little functionality that can not be more conveniently accessed via [gam](#). Penalized weighted least squares with linear equality and inequality constraints is provided by [pcls](#).

For a complete list of functions type `library(help=mgcv)`. See also [mgcv.FAQ](#).

```

---

mgcv.parallel

Parallel computation in mgcv.

---

## Description

mgcv can make some use of multiple cores or a cluster.

**bam** can use an openMP based parallelization approach alongside discretisation of covariates to achieve substantial speed ups. This is selected using the `discrete=TRUE` option to **bam**, with the number of threads controlled via the `nthreads` argument. This is the approach that scales best. See example below.

Alternatively, function **bam** can use the facilities provided in the **parallel** package. See examples below. Note that most multi-core machines are memory bandwidth limited, so parallel speed up tends to be rather variable.

Function **gam** can use parallel threads on a (shared memory) multi-core machine via openMP (where this is supported). To do this, set the desired number of threads by setting `nthreads` to the number of cores to use, in the `control` argument of **gam**. Note that, for the most part, only the dominant  $O(np^2)$  steps are parallelized (n is number of data, p number of parameters). For additive Gaussian models estimated by GCV, the speed up can be disappointing as these employ an  $O(p^3)$  SVD step that can also have substantial cost in practice. **magic** can also use multiple cores, but the same comments apply as for the GCV Gaussian additive model.

When using **NCV** with **gam** worthwhile performance improvements are available by setting `ncv.threads` in **gam.control**.

If `control$nthreads` is set to more than the number of cores detected, then only the number of detected cores is used. Note that using virtual cores usually gives very little speed up, and can even slow computations slightly. For example, many Intel processors reporting 4 cores actually have 2 physical cores, each with 2 virtual cores, so using 2 threads gives a marked increase in speed, while using 4 threads makes little extra difference.

Note that on Intel and similar processors the maximum performance is usually achieved by disabling Hyper-Threading in BIOS, and then setting the number of threads to the number of physical cores

used. This prevents the operating system scheduler from sending 2 floating point intensive threads to the same physical core, where they have to share a floating point unit (and cache) and therefore slow each other down. The scheduler tends to do this under the manager - worker multi-threading approach used in mgcv, since the manager thread looks very busy up to the point at which the workers are set to work, and at the point of scheduling the scheduler has no way of knowing that the manager thread actually has nothing more to do until the workers are finished. If you are working on a many cored platform where you can not disable hyper-threading then it may be worth setting the number of threads to one less than the number of physical cores, to reduce the frequency of such scheduling problems.

mgcv's work splitting always makes the simple assumption that all your cores are equal, and you are not sharing them with other floating point intensive threads.

In addition to hyper-threading several features may lead to apparently poor scaling. The first is that many CPUs have a Turbo mode, whereby a few cores can be run at higher frequency, provided the overall power used by the CPU does not exceed design limits, however it is not possible for all cores on the CPU to run at this frequency. So as you add threads eventually the CPU frequency has to be reduced below the Turbo frequency, with the result that you don't get the expected speed up from adding cores. Secondly, most modern CPUs have their frequency set dynamically according to load. You may need to set the system power management policy to favour high performance in order to maximize the chance that all threads run at the speed you were hoping for (you can turn off dynamic power control in BIOS, but then you turn off the possibility of Turbo also).

Because the computational burden in mgcv is all in the linear algebra, then parallel computation may provide reduced or no benefit with a tuned BLAS. This is particularly the case if you are using a multi threaded BLAS, but a BLAS that is tuned to make efficient use of a particular cache size may also experience loss of performance if threads have to share the cache.

### Examples

```
illustration of multi-threading with gam...

require(mgcv);set.seed(9)
dat <- gamSim(1,n=2000,dist="poisson",scale=.1)
k <- 12;bs <- "cr";ctrl <- list(nthreads=2)

system.time(b1<-gam(y~s(x0,bs=bs)+s(x1,bs=bs)+s(x2,bs=bs,k=k)
, family=poisson,data=dat,method="REML"))[3]

system.time(b2<-gam(y~s(x0,bs=bs)+s(x1,bs=bs)+s(x2,bs=bs,k=k),
family=poisson,data=dat,method="REML",control=ctrl))[3]

Poisson example on a cluster with 'bam'.
Note that there is some overhead in initializing the
computation on the cluster, associated with loading
the Matrix package on each node. Sample sizes are low
here to keep example quick -- for such a small model
little or no advantage is likely to be seen.
k <- 13;set.seed(9)
```

```

dat <- gamSim(1,n=6000,dist="poisson",scale=.1)

require(parallel)
nc <- 2 ## cluster size, set for example portability
if (detectCores()>1) { ## no point otherwise
 cl <- makeCluster(nc)
 ## could also use makeForkCluster, but read warnings first!
} else cl <- NULL

system.time(b3 <- bam(y ~ s(x0,bs=bs,k=7)+s(x1,bs=bs,k=7)+s(x2,bs=bs,k=k)
 ,data=dat,family=poisson(),chunk.size=5000,cluster=cl))

fv <- predict(b3,cluster=cl) ## parallel prediction

if (!is.null(cl)) stopCluster(cl)
b3

Alternative, better scaling example, using the discrete option with bam...

system.time(b4 <- bam(y ~ s(x0,bs=bs,k=7)+s(x1,bs=bs,k=7)+s(x2,bs=bs,k=k)
 ,data=dat,family=poisson(),discrete=TRUE,nthreads=2))

```

mini.roots

---

*Obtain square roots of penalty matrices*

---

## Description

INTERNAL function to obtain square roots,  $B[[i]]$ , of the penalty matrices  $S[[i]]$ 's having as few columns as possible.

## Usage

```
mini.roots(S, off, np, rank = NULL)
```

## Arguments

|                   |                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>S</code>    | a list of penalty matrices, in packed form.                                                                                                    |
| <code>off</code>  | a vector where the $i$ -th element is the offset for the $i$ -th matrix. The elements in columns $1:off[i]$ of $B[[i]]$ will be equal to zero. |
| <code>np</code>   | total number of parameters.                                                                                                                    |
| <code>rank</code> | here $rank[i]$ is optional supplied rank of $S[[i]]$ . Set $rank[i] < 1$ , or $rank=NULL$ to estimate.                                         |

## Value

A list of matrix square roots such that  $S[[i]] = B[[i]] \%*\% t(B[[i]])$ .

## Author(s)

missing.data

*Missing data in GAMs***Description**

If there are missing values in the response or covariates of a GAM then the default is simply to use only the ‘complete cases’. If there are many missing covariates, this can get rather wasteful. One possibility is then to use imputation. Another is to substitute a simple random effects model in which the by variable mechanism is used to set  $s(x)$  to zero for any missing  $x$ , while a Gaussian random effect is then substituted for the ‘missing’  $s(x)$ . See the example for details of how this works, and [gam.models](#) for the necessary background on by variables.

**Author(s)**

Simon Wood <simon.wood@r-project.org>

**See Also**

**Examples**

```
The example takes a couple of minutes to run...

require(mgcv)
par(mfrow=c(4,4),mar=c(4,4,1,1))
for (sim in c(1,7)) { ## cycle over uncorrelated and correlated covariates
 n <- 350;set.seed(2)
 ## simulate data but randomly drop 300 covariate measurements
 ## leaving only 50 complete cases...
 dat <- gamSim(sim,n=n,scale=3) ## 1 or 7
 drop <- sample(1:n,300) ## to
 for (i in 2:5) dat[drop[1:75+(i-2)*75],i] <- NA

 ## process data.frame producing binary indicators of missingness,
 ## mx0, mx1 etc. For each missing value create a level of a factor
 ## idx0, idx1, etc. So idx0 has as many levels as x0 has missing
 ## values. Replace the NA's in each variable by the mean of the
 ## non missing for that variable...

 dname <- names(dat)[2:5]
 dat1 <- dat
 for (i in 1:4) {
 by.name <- paste("m",dname[i],sep="")
 dat1[[by.name]] <- is.na(dat1[[dname[i]]])
 dat1[[dname[i]][dat1[[by.name]]]] <- mean(dat1[[dname[i]]],na.rm=TRUE)
 lev <- rep(1,n);lev[dat1[[by.name]]] <- 1:sum(dat1[[by.name]])
 id.name <- paste("id",dname[i],sep="")
 dat1[[id.name]] <- factor(lev)
 dat1[[by.name]] <- as.numeric(dat1[[by.name]])
 }

 ## Fit a gam, in which any missing value contributes zero
 ## to the linear predictor from its smooth, but each
```

```

missing has its own random effect, with the random effect
variances being specific to the variable. e.g.
for s(x0,by=ordered(!mx0)), declaring the `by' as an ordered
factor ensures that the smooth is centred, but multiplied
by zero when mx0 is one (indicating a missing x0). This means
that any value (within range) can be put in place of the
NA for x0. s(id0,bs="re",by=mx0) produces a separate Gaussian
random effect for each missing value of x0 (in place of s(x0),
effectively). The `by' variable simply sets the random effect to
zero when x0 is non-missing, so that we can set id0 to any
existing level for these cases.

b <- bam(y~s(x0,by=ordered(!mx0))+s(x1,by=ordered(!mx1))+
 s(x2,by=ordered(!mx2))+s(x3,by=ordered(!mx3))+
 s(id0,bs="re",by=mx0)+s(id1,bs="re",by=mx1)+
 s(id2,bs="re",by=mx2)+s(id3,bs="re",by=mx3)
 ,data=dat1,discrete=TRUE)

for (i in 1:4) plot(b,select=i) ## plot the smooth effects from b

fit the model to the `complete case' data...
b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat,method="REML")
plot(b2) ## plot the complete case results
}

```

model.matrix.gam

*Extract model matrix from GAM fit*

---

## Description

Obtains the model matrix from a fitted gam object.

## Usage

```

S3 method for class 'gam'
model.matrix(object, ...)

```

## Arguments

|        |                                                          |
|--------|----------------------------------------------------------|
| object | fitted model object of class gam as produced by gam().   |
| ...    | other arguments, passed to <a href="#">predict.gam</a> . |

## Details

Calls [predict.gam](#) with no newdata argument and type="lpmatrix" in order to obtain the model matrix of object.

## Value

A model matrix.

model.matrix(mod)
```

---

mono.con

*Monotonicity constraints for a cubic regression spline*

---

**Description**

Finds linear constraints sufficient for monotonicity (and optionally upper and/or lower boundedness) of a cubic regression spline. The basis representation assumed is that given by the gam, "cr" basis: that is the spline has a set of knots, which have fixed x values, but the y values of which constitute the parameters of the spline.

**Usage**

```
mono.con(x, up=TRUE, lower=NA, upper=NA)
```

**Arguments**

|       |                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------|
| x     | The array of knot locations.                                                                          |
| up    | If TRUE then the constraints imply increase, if FALSE then decrease.                                  |
| lower | This specifies the lower bound on the spline unless it is NA in which case no lower bound is imposed. |
| upper | This specifies the upper bound on the spline unless it is NA in which case no upper bound is imposed. |

**Details**

Consider the natural cubic spline passing through the points  $\{x_i, p_i : i = 1 \dots n\}$ . Then it is possible to find a relatively small set of linear constraints on  $\mathbf{p}$  sufficient to ensure monotonicity (and bounds if required):  $\mathbf{A}\mathbf{p} \geq \mathbf{b}$ . Details are given in Wood (1994).

**Value**

a list containing constraint matrix **A** and constraint vector **b**.

|       |                                       |
|-------|---------------------------------------|
| mroot | <i>Smallest square root of matrix</i> |
|-------|---------------------------------------|

---

**Description**

Find a square root of a positive semi-definite matrix, having as few columns as possible. Uses either pivoted Cholesky decomposition or singular value decomposition to do this.

**Usage**

```
mroot(A, rank=NULL, method="chol")
```

**Arguments**

|               |                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>A</b>      | The positive semi-definite matrix, a square root of which is to be found.                                                                                                                              |
| <b>rank</b>   | if the rank of the matrix <b>A</b> is known then it should be supplied. <code>NULL</code> or <code>&lt;1</code> imply that it should be estimated.                                                     |
| <b>method</b> | "chol" to use pivoted Cholesky decompositon, which is fast but tends to over-estimate rank. "svd" to use singular value decomposition, which is slower, but is the most accurate way to estimate rank. |

**Details**

The function is primarily of use for turning penalized regression problems into ordinary regression problems. Given that **A** is positive semi-definite the SVD option actually uses a symmetric eigen routine, which gives the same result more efficiently.

**Value**

A matrix, **B** with as many columns as the rank of **A**, and such that  $\mathbf{A} = \mathbf{B}\mathbf{B}'$ .

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

```
require(mgcv)
set.seed(0)
a <- matrix(runif(24),6,4)
A <- a%*%t(a) ## A is +ve semi-definite, rank 4
B <- mroot(A) ## default pivoted choleski method
tol <- 100*.Machine$double.eps
chol.err <- max(abs(A-B%*%t(B)));chol.err
if (chol.err>tol) warning("mroot (chol) suspect")
B <- mroot(A,method="svd") ## svd method
svd.err <- max(abs(A-B%*%t(B)));svd.err
if (svd.err>tol) warning("mroot (svd) suspect")
```

---

multinom

---

*GAM multinomial logistic regression*

---

**Description**

Family for use with [gam](#), implementing regression for categorical response data. Categories must be coded 0 to K, where K is a positive integer. [gam](#) should be called with a list of K formulae, one for each category except category zero (extra formulae for shared terms may also be supplied: see [formula.gam](#)). The first formula also specifies the response variable.

**Usage**

```
multinom(K=1)
```

**Arguments**

K                      There are K+1 categories and K linear predictors.

**Details**

The model has K linear predictors,  $\eta_j$ , each dependent on smooth functions of predictor variables, in the usual way. If response variable, y, contains the class labels 0,...,K then the likelihood for  $y>0$  is  $\exp(\eta_y)/\{1 + \sum_j \exp(\eta_j)\}$ . If  $y=0$  the likelihood is  $1/\{1 + \sum_j \exp(\eta_j)\}$ . In the two class case this is just a binary logistic regression model. The implementation uses the approach to GAMLSS models described in Wood, Pya and Saefken (2016).

The residuals returned for this model are simply the square root of -2 times the deviance for each observation, with a positive sign if the observed y is the most probable class for this observation, and a negative sign otherwise.

Use predict with type="response" to get the predicted probabilities in each category.

Note that the model is not completely invariant to category relabelling, even if all linear predictors have the same form. Realistically this model is unlikely to be suitable for problems with large numbers of categories. Missing categories are not supported.

**Value**

An object of class `general.family`.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>, with a variance bug fix from Max Goplerud.

---

mvn*Multivariate normal additive models*

---

**Description**

Family for use with [gam](#) implementing smooth multivariate Gaussian regression. The means for each dimension are given by a separate linear predictor, which may contain smooth components. Extra linear predictors may also be specified giving terms which are shared between components (see [formula.gam](#)). The Choleski factor of the response precision matrix is estimated as part of fitting.

**Usage**

```
mvn(d=2)
```

**Arguments**

`d`                      The dimension of the response (>1).

**Details**

The response is `d` dimensional multivariate normal, where the covariance matrix is estimated, and the means for each dimension have separate linear predictors. Model specification is via a list of `gam` like formulae - one for each dimension. See example.

Currently the family ignores any prior weights, and is implemented using first derivative information sufficient for BFGS estimation of smoothing parameters. "response" residuals give raw residuals, while "deviance" residuals are standardized to be approximately independent standard normal if all is well.

**Value**

An object of class `general.family`.

## Description

NCV estimates smoothing parameters by optimizing the average ability of a model to predict subsets of data when subsets of data are omitted from fitting. Usually the predicted subset is a subset of the omitted subset. If both subsets are the same single datapoint, and the average is over all datapoints, then NCV is leave-one-out cross validation. QNCV is a quadratic approximation to NCV, guaranteed finite for any family link combination.

In detail, suppose that a model is estimated by minimizing a penalized loss

$$\sum_i D(y_i, \theta_i) + \sum_j \lambda_j \beta^T S_j \beta$$

where  $D$  is a loss (such as a negative log likelihood), dependent on response  $y_i$  and parameter vector  $\theta_i$ , which in turn depends on covariates via one or more smooth linear predictors with coefficients  $\beta$ . The quadratic penalty terms penalize model complexity:  $S_j$  is a known matrix and  $\lambda_j$  an unknown smoothing parameter. Given smoothing parameters the penalized loss is readily minimized to estimate  $\beta$ .

The smoothing parameters also have to be estimated. To this end, choose  $k = 1, \dots, m$  subsets  $\alpha(k) \subset \{1, \dots, n\}$  and  $\delta(k) \subset \{1, \dots, n\}$ . Usually  $\delta(k)$  is a subset of (or equal to)  $\alpha(k)$ . Let  $\theta_i^{\alpha(k)}$  denote the estimate of  $\theta_i$  when the points indexed by  $\alpha(k)$  are omitted from fitting. Then the NCV criterion

$$V = \sum_{k=1}^m \sum_{i \in \delta(k)} D(y_i, \theta_i^{\alpha(k)})$$

is minimized w.r.t. the smoothing parameters,  $\lambda_j$ . If  $m = n$  and  $\alpha(k) = \delta(k) = k$  then ordinary leave-one-out cross validation is recovered. This formulation covers many of the variants of cross validation reviewed in Arlot and Celisse (2010), for example.

Except for a quadratic loss,  $V$  can not be computed exactly, but it can be computed to  $O(n^{-2})$  accuracy (fixed basis size), by taking single Newton optimization steps from the full data  $\beta$  estimates to the equivalent when each  $\alpha(k)$  is dropped. This is what `mgcv` does. The Newton steps require update of the full model Hessian to the equivalent when each datum is dropped. This can be achieved at  $O(p^2)$  cost, where  $p$  is the dimension of  $\beta$ . Hence, for example, the ordinary cross validation criterion is computable at the  $O(np^2)$  cost of estimating the model given smoothing parameters.

The NCV score computed in this way is optimized using a BFGS quasi-Newton method, adapted to the case in which smoothing parameters tending to infinity may cause indefiniteness.

For `bam(..., discrete=TRUE)` NCV can be used to estimate the smoothing parameters of the working penalized weighted linear model. This is typically very expensive relative to REML estimation, but the cost can be mitigated by basing the NCV criterion on a sample (usually random of the neighbourhoods). Note that in the case in which leave-out-neighbourhood CV is used to reduce the effects of autocorrelation, it is important to supply a neighbourhood for each observation, and to supply a sample element in `nei`. This ensures that the parameter covariance matrix is estimated correctly.

### Spatial and temporal short range autocorrelation

A routine applied problem is that smoothing parameters tend to be underestimated in the presence of un-modelled short range autocorrelation, as the smooths try to fit the local excursions in the data caused by the local autocorrelation. Cross validation will tend to 'fit the noise' when there is autocorrelation, since a model that fits the noise in the data correlated with an omitted datum, will also tend to closely fit the noise in the omitted datum, because of the correlation. That is autocorrelation works against the avoidance of overfit that cross validation seeks to achieve.

For short range autocorrelation the problems can be avoided, or at least mitigated, by predicting each datum when all the data in its 'local' neighbourhood are omitted. The neighbourhoods being constructed in order that un-modelled correlation is minimized between the point of interest and points outside its neighbourhood. That is we set  $m = n$ ,  $\delta(k) = k$  and  $\alpha(k) = \text{nei}(k)$ , where  $\text{nei}(k)$  are the indices of the neighbours of point  $k$ . This approach has been known for a long time (e.g. Chu and Marron, 1991; Robert et al. 2017), but was previously rather too expensive for regular use for smoothing parameter estimation.

### Specifying the neighbourhoods

The neighbourhood subsets  $\alpha(k)$  and  $\delta(k)$  have to be supplied to `gam`, and the `nei` argument does this. It is a list with the following arguments.

- `a` is the vector of indices to be dropped for each neighbourhood.
- `ma` gives the end of each neighbourhood. So `nei$a[(nei$ma[j-1]+1):nei$ma[j]]` gives the points dropped for the neighbourhood `j`: that is  $\alpha(j)$ .
- `d` is the vector of indices of points to predict.
- `md` gives the corresponding endpoints `md`. So `nei$d[(nei$md[j-1]+1):nei$md[j]]` indexes the points to predict for neighbourhood `j`: that is  $\delta(j)$ .
- `sample` is an optional element used by `bam`. If it is a single number it gives the number of neighbourhoods to randomly sample to construct the NCV criterion. If it is a vector then it should contain the indices of the neighbourhoods to use.

- `jackknife` is an optional element used by `gam`. If supplied and `TRUE` then variance estimates are based on the raw Jackknife estimate, if `FALSE` then on the standard Bayesian results. If not supplied (usual) then an estimator accounting for the neighbourhood structure is used, that largely accounts for any correlation present within neighbourhoods. `jackknife` is ignored if NCV is being calculated for a model where another method is used for smoothing parameter selection.

If `nei==NULL` (or `a` or `ma` are missing) then leave-one-out cross validation is used. If `nei` is supplied but NCV is not selected as the smoothing parameter estimation method, then it is simply computed (but not optimized).

### Numerical issues

If a model is specified in which some coefficient values,  $\beta$ , have non-finite likelihood then the NCV criterion computed with single Newton steps could also be non-finite. A simple fix replaces the NCV criterion with a quadratic approximation to the criterion around the full data fit. The quadratic approximation is always finite. This 'QNCV' is essential for some families, such as `gevlss`. QNCV is not needed for `bam` estimation.

Although the leading order cost of NCV is the same as REML or GCV, the actual cost is higher because the dominant operations costs are in matrix-vector, rather than matrix-matrix, operations, so BLAS speed ups are small. However multi-core computing is worthwhile for NCV. See the option `ncv.threads` in `gam.control`.

```

negbin

*GAM negative binomial families*

## Description

The gam modelling function is designed to be able to use the [negbin](#) family (a modification of MASS library negative.binomial family by Venables and Ripley), or the [nb](#) function designed for integrated estimation of parameter theta.  $\theta$  is the parameter such that  $\text{var}(y) = \mu + \mu^2/\theta$ , where  $\mu = E(y)$ .

Two approaches to estimating theta are available (with [gam](#) only):

- With negbin then if ‘performance iteration’ is used for smoothing parameter estimation (see [gam](#)), then smoothing parameters are chosen by GCV and theta is chosen in order to ensure that the Pearson estimate of the scale parameter is as close as possible to 1, the value that the scale parameter should have.
- If ‘outer iteration’ is used for smoothing parameter selection with the nb family then theta is estimated alongside the smoothing parameters by ML or REML.

To use the first option, set the optimizer argument of [gam](#) to "perf" (it can sometimes fail to converge).

## Usage

```

negbin(theta = stop("'theta' must be specified"), link = "log")
nb(theta = NULL, link = "log")

```

## Arguments

|       |                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| theta | Either i) a single value known value of theta or ii) two values of theta specifying the endpoints of an interval over which to search for theta (this is an option only for negbin, and is deprecated). For nb then a positive supplied theta is treated as a fixed known parameter, otherwise it is estimated (the absolute value of a negative theta is taken as a starting value). |
| link  | The link function: one of "log", "identity" or "sqrt"                                                                                                                                                                                                                                                                                                                                 |

## Details

nb allows estimation of the theta parameter alongside the model smoothing parameters, but is only usable with `gam` or `bam` (not `gamm`).

For negbin, if a single value of theta is supplied then it is always taken as the known fixed value and this is useable with `bam` and `gamm`. If theta is two numbers (`theta[2]>theta[1]`) then they are taken as specifying the range of values over which to search for the optimal theta. This option is deprecated and should only be used with performance iteration estimation (see `gam` argument optimizer), in which case the method of estimation is to choose  $\hat{\theta}$  so that the GCV (Pearson) estimate of the scale parameter is one (since the scale parameter is one for the negative binomial). In this case  $\theta$  estimation is nested within the IRLS loop used for GAM fitting. After each call to fit an iteratively weighted additive model to the IRLS pseudodata, the  $\theta$  estimate is updated. This is done by conditioning on all components of the current GCV/Pearson estimator of the scale parameter except  $\theta$  and then searching for the  $\hat{\theta}$  which equates this conditional estimator to one. The search is a simple bisection search after an initial crude line search to bracket one. The search will terminate at the upper boundary of the search region is a Poisson fit would have yielded an estimated scale parameter  $<1$ .

## Value

For negbin an object inheriting from class family, with additional elements

|          |                                                                                                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------|
| dvar     | the function giving the first derivative of the variance function w.r.t. mu.                                                       |
| d2var    | the function giving the second derivative of the variance function w.r.t. mu.                                                      |
| getTheta | A function for retrieving the value(s) of theta. This also useful for retriving the estimate of theta after fitting (see example). |

For nb an object inheriting from class extended.family.

## WARNINGS

`gamm` does not support theta estimation

The negative binomial functions from the MASS library are no longer supported.

## Author(s)

## Examples

```
library(mgcv)
set.seed(3)
n<-400
dat <- gamSim(1,n=n)
g <- exp(dat$f/5)
```

```
negative binomial data...
dat$y <- rnbinom(g,size=3,mu=g)
known theta fit ...
b0 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negbin(3),data=dat)
plot(b0,pages=1)
print(b0)

same with theta estimation...
b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=nb(),data=dat)
plot(b,pages=1)
print(b)
b$family$getTheta(TRUE) ## extract final theta estimate

another example...
set.seed(1)
f <- dat$f
f <- f - min(f)+5;g <- f^2/10
dat$y <- rnbinom(g,size=3,mu=g)
b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=nb(link="sqrt"),
 data=dat,method="REML")
plot(b2,pages=1)
print(b2)
rm(dat)
```

---

new.name

---

*Obtain a name for a new variable that is not already in use*

---

## Description

`gamm` works by transforming a GAMM into something that can be estimated by `lme`, but this involves creating new variables, the names of which should not clash with the names of other variables on which the model depends. This simple service routine checks a suggested name against a list of those in use, and if necessary modifies it so that there is no clash.

## Usage

```
new.name(proposed,old.names)
```

## Arguments

|           |                                               |
|-----------|-----------------------------------------------|
| proposed  | a suggested name                              |
| old.names | An array of names that must not be duplicated |

## Value

A name that is not in `old.names`.

## Author(s)

Simon N. Wood <simon.wood@r-project.org>

```
require(mgcv)
old <- c("a", "tuba", "is", "tubby")
new.name("tubby", old)
```

---

notExp*Functions for better-than-log positive parameterization*

---

**Description**

It is common practice in statistical optimization to use log-parameterizations when a parameter ought to be positive. i.e. if an optimization parameter  $a$  should be non-negative then we use  $a = \exp(b)$  and optimize with respect to the unconstrained parameter  $b$ . This often works well, but it does imply a rather limited working range for  $b$ : using 8 byte doubles, for example, if  $b$ 's magnitude gets much above 700 then  $a$  overflows or underflows. This can cause problems for numerical optimization methods.

notExp is a monotonic function for mapping the real line into the positive real line with much less extreme underflow and overflow behaviour than exp. It is a piece-wise function, but is continuous to second derivative: see the source code for the exact definition, and the example below to see what it looks like.

notLog is the inverse function of notExp.

The major use of these functions was originally to provide more robust pdMat classes for lme for use by [gamm](#). Currently the [notExp2](#) and [notLog2](#) functions are used in their place, as a result of changes to the nlme optimization routines.

**Usage**

```
notExp(x)
```

```
notLog(x)
```

**Arguments**

$x$                       Argument array of real numbers (notExp) or positive real numbers (notLog).

**Value**

An array of function values evaluated at the supplied argument values.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

**See Also**

[pdTens](#), [pdIdnot](#), [gamm](#)

## Examples

```
Illustrate the notExp function:
less steep than exp, but still monotonic.
require(mgcv)
x <- -100:100/10
op <- par(mfrow=c(2,2))
plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
x <- x/4
plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
par(op)
range(notLog(notExp(x))-x) # show that inverse works!
```

notExp2

*Alternative to log parameterization for variance components*

## Description

notLog2 and notExp2 are alternatives to log and exp or [notLog](#) and [notExp](#) for re-parameterization of variance parameters. They are used by the [pdTens](#) and [pdIdnot](#) classes which in turn implement smooths for [gamm](#).

The functions are typically used to ensure that smoothing parameters are positive, but the notExp2 is not monotonic: rather it cycles between ‘effective zero’ and ‘effective infinity’ as its argument changes. The notLog2 is the inverse function of the notExp2 only over an interval centered on zero.

Parameterizations using these functions ensure that estimated smoothing parameters remain positive, but also help to ensure that the likelihood is never indefinite: once a working parameter pushes a smoothing parameter below ‘effective zero’ or above ‘effective infinity’ the cyclic nature of the notExp2 causes the likelihood to decrease, where otherwise it might simply have flattened.

This parameterization is really just a numerical trick, in order to get lme to fit gamm models, without failing due to indefiniteness. Note in particular that asymptotic results on the likelihood/REML criterion are not invalidated by the trick, unless parameter estimates end up close to the effective zero or effective infinity: but if this is the case then the asymptotics would also have been invalid for a conventional monotonic parameterization.

This reparameterization was made necessary by some modifications to the underlying optimization method in lme introduced in nlme 3.1-62. It is possible that future releases will return to the [notExp](#) parameterization.

Note that you can reset ‘effective zero’ and ‘effective infinity’: see below.

## Usage

```
notExp2(x,d=.Options$mgcv.vc.logrange,b=1/d)
```

```
notLog2(x,d=.Options$mgcv.vc.logrange,b=1/d)
```

**Arguments**

|   |                                                                                                                                                               |
|---|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | Argument array of real numbers (notExp) or positive real numbers (notLog).                                                                                    |
| d | the range of notExp2 runs from $\exp(-d)$ to $\exp(d)$ . To change the range used by gamm reset <code>mgcv.vc.logrange</code> using <a href="#">options</a> . |
| b | determines the period of the cycle of notExp2.                                                                                                                |

**Value**

An array of function values evaluated at the supplied argument values.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

par(op)
```

---

null.space.dimension    *The basis of the space of un-penalized functions for a TPRS*

---

**Description**

The thin plate spline penalties give zero penalty to some functions. The space of these functions is spanned by a set of polynomial terms. `null.space.dimension` finds the dimension of this space,  $M$ , given the number of covariates that the smoother is a function of,  $d$ , and the order of the smoothing penalty,  $m$ . If  $m$  does not satisfy  $2m > d$  then the smallest possible dimension for the null space is found given  $d$  and the requirement that the smooth should be visually smooth.

**Usage**

```
null.space.dimension(d,m)
```

**Arguments**

- `d` is a positive integer - the number of variables of which the t.p.s. is a function.
- `m` a non-negative integer giving the order of the penalty functional, or signalling that the default order should be used.

**Details**

Thin plate splines are only visually smooth if the order of the wiggleness penalty,  $m$ , satisfies  $2m > d + 1$ . If  $2m < d + 1$  then this routine finds the smallest  $m$  giving visual smoothness for the given  $d$ , otherwise the supplied  $m$  is used. The null space dimension is given by:

$$M = (m + d - 1)! / (d!(m - 1)!)$$

which is the value returned.

**Value**

An integer (array), the null space dimension  $M$ .

**Examples**

```
require(mgcv)
null.space.dimension(2,0)
```

---

ocat

*GAM ordered categorical family*

---

**Description**

Family for use with [gam](#) or [bam](#), implementing regression for ordered categorical data. A linear predictor provides the expected value of a latent variable following a logistic distribution. The probability of this latent variable lying between certain cut-points provides the probability of the ordered categorical variable being of the corresponding category. The cut-points are estimated along side the model smoothing parameters (using the same criterion). The observed categories are coded 1, 2, 3, ... up to the number of categories.

**Usage**

```
ocat(theta=NULL,link="identity",R=NULL)
```

## Arguments

|                    |                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>theta</code> | cut point parameter vector (dimension $R-2$ ). If supplied and all positive, then taken to be the cut point increments (first cut point is fixed at -1). If any are negative then absolute values are taken as starting values for cutpoint increments. |
| <code>link</code>  | The link function: only "identity" allowed at present (possibly for ever).                                                                                                                                                                              |
| <code>R</code>     | the number of categories.                                                                                                                                                                                                                               |

## Details

Such cumulative threshold models are only identifiable up to an intercept, or one of the cut points. Rather than remove the intercept, `ocat` simply sets the first cut point to -1. Use `predict.gam` with `type="response"` to get the predicted probabilities in each category.

## Value

An object of class `extended.family`.

```

---

one.se.rule

*The one standard error rule for smoother models*

---

## Description

The ‘one standard error rule’ (see e.g. Hastie, Tibshirani and Friedman, 2009) is a way of producing smoother models than those directly estimated by automatic smoothing parameter selection methods. In the single smoothing parameter case, we select the largest smoothing parameter within one standard error of the optimum of the smoothing parameter selection criterion. This approach can be generalized to multiple smoothing parameters estimated by REML or ML.

## Details

Under REML or ML smoothing parameter selection an asymptotic distributional approximation is available for the log smoothing parameters. Let  $\rho$  denote the log smoothing parameters that we want to increase to obtain a smoother model. The large sample distribution of the estimator of  $\rho$  is  $N(\rho, V)$  where  $V$  is the matrix returned by [sp.vcov](#). Drop any elements of  $\rho$  that are already at ‘effective infinity’, along with the corresponding rows and columns of  $V$ . The standard errors of the log smoothing parameters can be obtained from the leading diagonal of  $V$ . Let the vector of these be  $d$ . Now suppose that we want to increase the estimated log smoothing parameters by an amount  $\alpha d$ . We choose  $\alpha$  so that  $\alpha d^T V^{-1} d = \sqrt{2p}$ , where  $p$  is the dimension of  $d$  and  $2p$  the variance of a chi-squared r.v. with  $p$  degrees of freedom.

The idea is that we increase the log smoothing parameters in proportion to their standard deviation, until the RE/ML is increased by 1 standard deviation according to its asymptotic distribution.

pcls

*Penalized Constrained Least Squares Fitting*

## Description

Solves least squares problems with quadratic penalties subject to linear equality and inequality constraints using quadratic programming.

## Usage

pcls(M)

## Arguments

- M** is the single list argument to pcls. It should have the following elements:
- y** The response data vector.
  - w** A vector of weights for the data (often proportional to the reciprocal of the variance).
  - X** The design matrix for the problem, note that `ncol(M$X)` must give the number of model parameters, while `nrow(M$X)` should give the number of data.
  - C** Matrix containing any linear equality constraints on the problem (e.g.  $C\mathbf{p} = \mathbf{c}$ ). If you have no equality constraints initialize this to a zero by zero matrix. Note that there is no need to supply the vector  $\mathbf{c}$ , it is defined implicitly by the initial parameter estimates  $\mathbf{p}$ .
  - S** A list of penalty matrices.  $S[[i]]$  is the smallest contiguous matrix including all the non-zero elements of the  $i$ th penalty matrix. The first parameter it penalizes is given by `off[i]+1` (starting counting at 1).
  - off** Offset values locating the elements of  $M\$S$  in the correct location within each penalty coefficient matrix. (Zero offset implies starting in first location)
  - sp** An array of smoothing parameter estimates.
  - p** An array of feasible initial parameter estimates - these must satisfy the constraints, but should avoid satisfying the inequality constraints as equality constraints (unless these are constraints in `active`).
  - Ain** Matrix for the inequality constraints  $\mathbf{A}_{in}\mathbf{p} > \mathbf{b}_{in}$ .
  - bin** vector in the inequality constraints.
  - active** if present this indexes any inequality constraints currently active. Typically only used in applications calling pcls sequentially. Must never exceed dimension of  $\mathbf{p}$  minus the number of fixed constraints.

## Details

This solves the problem:

$$\text{minimise } \|\mathbf{W}^{1/2}(\mathbf{X}\mathbf{p} - \mathbf{y})\|^2 + \sum_{i=1}^m \lambda_i \mathbf{p}' \mathbf{S}_i \mathbf{p}$$

subject to constraints  $\mathbf{C}\mathbf{p} = \mathbf{c}$  and  $\mathbf{A}_{in}\mathbf{p} > \mathbf{b}_{in}$ , w.r.t.  $\mathbf{p}$  given the smoothing parameters  $\lambda_i$ .  $\mathbf{X}$  is a design matrix,  $\mathbf{p}$  a parameter vector,  $\mathbf{y}$  a data vector,  $\mathbf{W}$  a diagonal weight matrix,  $\mathbf{S}_i$  a positive semi-definite matrix of coefficients defining the  $i$ th penalty and  $\mathbf{C}$  a matrix of coefficients defining the linear equality constraints on the problem. The smoothing parameters are the  $\lambda_i$ . Note that  $\mathbf{X}$  must be of full column rank, at least when projected into the null space of any equality constraints.  $\mathbf{A}_{in}$  is a matrix of coefficients defining the inequality constraints, while  $\mathbf{b}_{in}$  is a vector involved in defining the inequality constraints.

Quadratic programming is used to perform the solution. The method used is designed for maximum stability with least squares problems: i.e.  $\mathbf{X}'\mathbf{X}$  is not formed explicitly. See Gill et al. 1981.

## Value

The function returns a vector of the estimated parameter values. This has an attribute `active` giving the indices of the active constraints. If none are active this attribute will be of length 0.

---

pdIdnot

---

*Overflow proof pdMat class for multiples of the identity matrix*

---

## Description

This set of functions is a modification of the pdMat class pdIdent from library nlme. The modification is to replace the log parameterization used in pdMat with a [notLog2](#) parameterization, since the latter avoids indefiniteness in the likelihood and associated convergence problems: the parameters also relate to variances rather than standard deviations, for consistency with the [pdTens](#) class. The functions are particularly useful for working with Generalized Additive Mixed Models where variance parameters/smoothing parameters can be very large or very small, so that overflow or underflow can be a problem.

These functions would not normally be called directly, although unlike the [pdTens](#) class it is easy to do so.

**Usage**

```
pdIdnot(value = numeric(0), form = NULL,
 nam = NULL, data = sys.frame(sys.parent()))
```

**Arguments**

|       |                                                              |
|-------|--------------------------------------------------------------|
| value | Initialization values for parameters. Not normally used.     |
| form  | A one sided formula specifying the random effects structure. |
| nam   | a names argument, not normally used with this class.         |
| data  | data frame in which to evaluate formula.                     |

**Details**

The following functions are provided: `Dim.pdIndot`, `coef.pdIdnot`, `corMatrix.pdIdnot`, `logDet.pdIdnot`, `pdConstruct.pdIdnot`, `pdFactor.pdIdnot`, `pdMatrix.pdIdnot`, `solve.pdIdnot`, `summary.pdIdnot`. (e.g. `mgcv::coef.pdIdnot` to access.)

Note that while the `pdFactor` and `pdMatrix` functions return the inverse of the scaled random effect covariance matrix or its factor, the `pdConstruct` function is initialised with estimates of the scaled covariance matrix itself.

**Value**

A class `pdIdnot` object, or related quantities. See the `nlme` documentation for further details.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

**See Also**

[te](#), [pdTens](#), [notLog2](#), [gamm](#)

**Examples**

```
see gamm
```

**Description**

This set of functions implements an nlme library pdMat class to allow tensor product smooths to be estimated by lme as called by gamm. Tensor product smooths have a penalty matrix made up of a weighted sum of penalty matrices, where the weights are the smoothing parameters. In the mixed model formulation the penalty matrix is the inverse of the covariance matrix for the random effects of a term, and the smoothing parameters (times a half) are variance parameters to be estimated. It's not possible to transform the problem to make the required random effects covariance matrix look like one of the standard pdMat classes: hence the need for the pdTens class. A [notLog2](#) parameterization ensures that the parameters are positive.

These functions (pdTens, pdConstruct.pdTens, pdFactor.pdTens, pdMatrix.pdTens, coef.pdTens and summary.pdTens) would not normally be called directly.

**Usage**

```
pdTens(value = numeric(0), form = NULL,
 nam = NULL, data = sys.frame(sys.parent()))
```

**Arguments**

|       |                                                                                                                                                                                                                                            |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | Initialization values for parameters. Not normally used.                                                                                                                                                                                   |
| form  | A one sided formula specifying the random effects structure. The formula should have an attribute S which is a list of the penalty matrices the weighted sum of which gives the inverse of the covariance matrix for these random effects. |
| nam   | a names argument, not normally used with this class.                                                                                                                                                                                       |
| data  | data frame in which to evaluate formula.                                                                                                                                                                                                   |

**Details**

If using this class directly note that it is worthwhile scaling the S matrices to be of 'moderate size', for example by dividing each matrix by its largest singular value: this avoids problems with lme defaults ([smooth.construct.tensor.smooth.spec](#) does this automatically).

This appears to be the minimum set of functions required to implement a new pdMat class.

Note that while the pdFactor and pdMatrix functions return the inverse of the scaled random effect covariance matrix or its factor, the pdConstruct function is sometimes initialised with estimates of the scaled covariance matrix, and sometimes intialized with its inverse.

**Value**

A class pdTens object, or its coefficients or the matrix it represents or the factor of that matrix. pdFactor returns the factor as a vector (packed column-wise) (pdMatrix always returns a matrix).

|         |                                                                                           |
|---------|-------------------------------------------------------------------------------------------|
| pen.edf | <i>Extract the effective degrees of freedom associated with each penalty in a gam fit</i> |
|---------|-------------------------------------------------------------------------------------------|

---

## Description

Finds the coefficients penalized by each penalty and adds up their effective degrees of freedom. Very useful for [t2](#) terms, but hard to interpret for terms where the penalties penalize overlapping sets of parameters (e.g. [te](#) terms).

## Usage

```
pen.edf(x)
```

## Arguments

x                      an object inheriting from gam

## Details

Useful for models containing [t2](#) terms, since it splits the EDF for the term up into parts due to different components of the smooth. This is useful for figuring out which interaction terms are actually needed in a model.

## Value

A vector of EDFs, named with labels identifying which penalty each EDF relates to.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

## See Also

[t2](#)

**Examples**

```

require(mgcv)
set.seed(20)
dat <- gamSim(1,n=400,scale=2) ## simulate data
following `t2' smooth basically separates smooth
of x0,x1 into main effects + interaction...

b <- gam(y~t2(x0,x1,bs="tp",m=1,k=7)+s(x2)+s(x3),
 data=dat,method="ML")
pen.edf(b)

label "rr" indicates interaction edf (range space times range space)
label "nr" (null space for x0 times range space for x1) is main
effect for x1.
label "rn" is main effect for x0
clearly interaction is negligible

second example with higher order marginals.

b <- gam(y~t2(x0,x1,bs="tp",m=2,k=7,full=TRUE)
 +s(x2)+s(x3),data=dat,method="ML")
pen.edf(b)

In this case the EDF is negligible for all terms in the t2 smooth
apart from the `main effects' (r2 and 2r). To understand the labels
consider the following 2 examples...
"r1" relates to the interaction of the range space of the first
marginal smooth and the first basis function of the null
space of the second marginal smooth
"2r" relates to the interaction of the second basis function of
the null space of the first marginal smooth with the range
space of the second marginal smooth.

```

---

place.knots

*Automatically place a set of knots evenly through covariate values*

---

**Description**

Given a univariate array of covariate values, places a set of knots for a regression spline evenly through the covariate values.

**Usage**

```
place.knots(x,nk)
```

**Arguments**

**x**                      array of covariate values (need not be sorted).

**nk**                     integer indicating the required number of knots.

**Details**

Places knots evenly throughout a set of covariates. For example, if you had 11 covariate values and wanted 6 knots then a knot would be placed at the first (sorted) covariate value and every second (sorted) value thereafter. With less convenient numbers of data and knots the knots are placed within intervals between data in order to achieve even coverage, where even means having approximately the same number of data between each pair of knots.

**Value**

An array of knot locations.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**See Also**

[smooth.construct.cc.smooth.spec](#)

**Examples**

```
require(mgcv)
x<-runif(30)
place.knots(x,7)
rm(x)
```

---

plot.gam

*Default GAM plotting*

---

**Description**

Takes a fitted gam object produced by `gam()` and plots the component smooth functions that make it up, on the scale of the linear predictor. Optionally derivatives of 1-D plots may be plotted. Optionally produces term plots for parametric model components as well.

**Usage**

```
S3 method for class 'gam'
plot(x, residuals=FALSE, rug=NULL, se=TRUE, pages=0, select=NULL, scale=-1,
 n=100, n2=40, n3=3, theta=30, phi=30, jit=FALSE, xlab=NULL,
 ylab=NULL, main=NULL, ylim=NULL, xlim=NULL, too.far=0.1,
 all.terms=FALSE, shade.col="gray80", shift=0,
 trans=I, seWithMean=FALSE, unconditional=FALSE, by.resids=FALSE,
 scheme=0, deriv=FALSE, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a fitted gam object as produced by <code>gam()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>residuals</code> | If TRUE then partial residuals are added to plots of 1-D smooths. If FALSE then no residuals are added. If this is an array of the correct length then it is used as the array of residuals to be used for producing partial residuals. If TRUE then the residuals are the working residuals from the IRLS iteration weighted by the (square root) IRLS weights, in order that they have constant variance if the model is correct. Partial residuals for a smooth term are the residuals that would be obtained by dropping the term concerned from the model, while leaving all other estimates fixed (i.e. the estimates for the term plus the residuals). |
| <code>rug</code>       | When TRUE the covariate to which the plot applies is displayed as a rug plot at the foot of each plot of a 1-d smooth, and the locations of the covariates are plotted as points on the contour plot representing a 2-d smooth. The default of NULL sets rug to TRUE when the dataset size is $\leq 10000$ and FALSE otherwise.                                                                                                                                                                                                                                                                                                                               |
| <code>se</code>        | when TRUE (default) upper and lower lines are added to the 1-d plots corresponding to 95% confidence limits. For 2-d plots, surfaces corresponding to lower and upper limits of 68% confidence intervals are contoured and overlayed on the contour plot for the estimate. If one or more numbers (between 0 and 1) are supplied then these are the confidence level used whatever the dimension. Currently scheme 2 uses 2 levels. Any value 1 or above resets to TRUE, failing which any value 0 or below rests to FALSE.                                                                                                                                   |
| <code>pages</code>     | (default 0) the number of pages over which to spread the output. For example, if <code>pages=1</code> then all terms will be plotted on one page with the layout performed automatically. Set to 0 to have the routine leave all graphics settings as they are.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>select</code>    | Allows the plot for a single model term to be selected for printing. e.g. if you just want the plot for the second smooth term set <code>select=2</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>scale</code>     | set to -1 (default) to have the same y-axis scale for each plot, and to 0 for a different y axis for each plot. Ignored if <code>ylim</code> supplied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>n</code>         | number of points used for each 1-d plot - for a nice smooth plot this needs to be several times the estimated degrees of freedom for the smooth. Default value 100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>n2</code>        | Square root of number of points used to grid estimates of 2-d functions for contouring.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>n3</code>        | Square root of number of panels to use when displaying 3 or 4 dimensional functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>theta</code>     | One of the perspective plot angles.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>phi</code>       | The other perspective plot angle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>jitter</code>    | Set to TRUE if you want rug plots for 1-d terms to be jittered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>xlab</code>      | If supplied then this will be used as the x label for all plots.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>ylab</code>      | If supplied then this will be used as the y label for all plots.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>main</code>      | Used as title (or z axis label) for plots if supplied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>ylim</code>      | If supplied then this pair of numbers are used as the y limits for each plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>xlim</code>      | If supplied then this pair of numbers are used as the x limits for each plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>too.far</code>   | If greater than 0 then this is used to determine when a location is too far from data to be plotted when plotting 2-D smooths. This is useful since smooths tend to go wild away from data. The data are scaled into the unit square before                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            | deciding what to exclude, and <code>too.far</code> is a distance within the unit square. Setting to zero can make plotting faster for large datasets, but care then needed with interpretation of plots.                                                                                                                                                                                                                                                                                                |
| <code>all.terms</code>     | if set to TRUE then the partial effects of parametric model components are also plotted, via a call to <a href="#">termplot</a> . Only terms of order 1 can be plotted in this way. Also see warnings.                                                                                                                                                                                                                                                                                                  |
| <code>shade.col</code>     | define the color used for shading confidence bands, for schemes that use this. For schemes using 2 colours this should be a 2 element vector of colours to over-ride defaults ( <a href="#">rgb</a> can be useful).                                                                                                                                                                                                                                                                                     |
| <code>shift</code>         | constant to add to each smooth (on the scale of the linear predictor) before plotting. Can be useful for some diagnostics, or with <code>trans</code> .                                                                                                                                                                                                                                                                                                                                                 |
| <code>trans</code>         | monotonic function to apply to each smooth (after any shift), before plotting. Monotonicity is not checked, but default plot limits assume it. <code>shift</code> and <code>trans</code> are occasionally useful as a means for getting plots on the response scale, when the model consists only of a single smooth.                                                                                                                                                                                   |
| <code>seWithMean</code>    | if TRUE the component smooths are shown with confidence intervals that include the uncertainty about the overall mean. If FALSE then the uncertainty relates purely to the centred smooth itself. If <code>seWithMean=2</code> then the intervals include the uncertainty in the mean of the fixed effects (but not in the mean of any uncentred smooths or random effects). Marra and Wood (2012) suggests that TRUE results in better coverage performance, and this is also suggested by simulation. |
| <code>unconditional</code> | if TRUE then the smoothing parameter uncertainty corrected covariance matrix is used to compute uncertainty bands, if available. Otherwise the bands treat the smoothing parameters as fixed.                                                                                                                                                                                                                                                                                                           |
| <code>by.resids</code>     | Should partial residuals be plotted for terms with by variables? Usually the answer is no, they would be meaningless.                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>scheme</code>        | Integer or integer vector selecting a plotting scheme for each plot. See details.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>deriv</code>         | set to TRUE to plot derivative of smooth w.r.t covariate for 1-D terms supporting this.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>...</code>           | other graphics parameters to pass on to plotting commands. See details for smooth plot specific options.                                                                                                                                                                                                                                                                                                                                                                                                |

## Details

Produces default plot showing the smooth components of a fitted GAM, and optionally parametric terms as well, when these can be handled by [termplot](#).

For 1-D smooths with supporting plot methods `deriv=TRUE` specifies plotting of derivative of the smooth w.r.t. the covariate and its confidence band. Such derivatives are the direct analogues of the coefficients in a linear regression, giving the rate of change of the linear predictor w.r.t. the covariate. The plot label is modified to indicate that the derivative is being plotted.

For smooth terms `plot.gam` actually calls plot method functions depending on the class of the smooth. Currently [random.effects](#), Markov random fields ([mrf](#)), [Spherical.Spline](#) and [factor.smooth.interaction](#) terms have special methods (documented in their help files), the rest use the defaults described below.

For plots of 1-d smooths, the x axis of each plot is labelled with the covariate name, while the y axis is labelled `s(cov, edf)` where `cov` is the covariate name, and `edf` the estimated (or user defined for regression splines) degrees of freedom of the smooth. `scheme == 0` produces a smooth curve with dashed curves indicating 2 standard error bounds. `scheme == 1` illustrates the error bounds using a shaded region. `scheme == 2` shows 68% and 95% confidence regions (levels can be reset by `se`).

For `scheme==0`, contour plots are produced for 2-d smooths with the x-axes labelled with the first covariate name and the y axis with the second covariate name. The main title of the plot is something like `s(var1, var2, edf)`, indicating the variables of which the term is a function, and the estimated degrees of freedom for the term. When `se=TRUE`, estimator variability is shown by overlaying contour plots for 68% confidence limits. If `se` is a positive number in (0,1) then contour plots are at the estimate and confidence limits at the given level. Contour levels are chosen to try and ensure reasonable separation of the contours of the different plots, but this is not always easy to achieve. Note that these plots can not be modified to the same extent as the other plot.

For 2-d smooths `scheme==1` produces a perspective plot, while `scheme==2` produces a heatmap, with overlaid contours and `scheme==3` a greyscale heatmap (`contour.col` controls the contour colour).

Smooths of 3 and 4 variables are displayed as tiled heatmaps with overlaid contours. In the 3 variable case the third variable is discretized and a contour plot of the first 2 variables is produced for each discrete value. The panels in the lower and upper rows are labelled with the corresponding third variable value. The lowest value is bottom left, and highest at top right. For 4 variables, two of the variables are coarsely discretized and a square array of image plots is produced for each combination of the discrete values. The first two arguments of the smooth are the ones used for the image/contour plots, unless a tensor product term has 2D marginals, in which case the first 2D marginal is image/contour plotted. `n3` controls the number of panels. See also [vis.gam](#).

Fine control of plots for parametric terms can be obtained by calling [termplot](#) directly, taking care to use its `terms` argument.

Note that, if `seWithMean=TRUE`, the confidence bands include the uncertainty about the overall mean. In other words although each smooth is shown centred, the confidence bands are obtained as if every other term in the model was constrained to have average 0, (average taken over the covariate values), except for the smooth concerned. This seems to correspond more closely to how most users interpret componentwise intervals in practice, and also results in intervals with close to nominal (frequentist) coverage probabilities by an extension of Nychka's (1988) results presented in Marra and Wood (2012). There are two possible variants of this approach. In the default variant the extra uncertainty is in the mean of all other terms in the model (fixed and random, including uncentred smooths). Alternatively, if `seWithMean=2` then only the uncertainty in parametric fixed effects is included in the extra uncertainty (this latter option actually tends to lead to wider intervals when the model contains random effects).

Several smooth plots methods using [image](#) will accept an `hcolors` argument, which can be anything documented in [heat.colors](#) (in which case something like `hcolors=rainbow(50)` is appropriate), or the [grey](#) function (in which case something like `hcolors=grey(0:50/50)` is needed). Another option is `contour.col` which will set the contour colour for some plots. These options are useful for producing grey scale pictures instead of colour.

Sometimes you may want a small change to a default plot, and the arguments to `plot.gam` just won't let you do it. In this case, the quickest option is sometimes to clone the `smooth.construct` and `Predict.matrix` methods for the smooth concerned, modifying only the returned smoother class (e.g. to `foo.smooth`). Then copy the plot method function for the original class (e.g. `mgcv:::plot.mgcv.smooth`), modify the source code to plot exactly as you want and rename the plot method function (e.g. `plot.foo.smooth`). You can then use the cloned smooth in models (e.g. `s(x, bs="foo")`), and it will automatically plot using the modified plotting function.

## Value

The functions main purpose is its side effect of generating plots. It also silently returns a list of the data used to produce the plots, which can be used to generate customized plots.

**WARNING**

Note that the behaviour of this function is not identical to `plot.gam()` in S-PLUS.

Plotting can be slow for models fitted to large datasets. Set `rug=FALSE` to improve matters. If it's still too slow set `too.far=0`, but then take care not to overinterpret smooths away from supporting data.

Plots of 2-D smooths with standard error contours shown can not easily be customized.

`all.terms` uses `termplot` which looks for the original data in the environment of the fitted model object formula. Since `gam` resets this environment to avoid large saved model objects containing data in hidden environments, this can fail.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

Henric Nilsson <henric.nilsson@statisticon.se> donated the code for the shade option.

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

**Examples**

```
library(mgcv)
set.seed(0)
fake some data...
f1 <- function(x) {exp(2 * x)}
f2 <- function(x) {
 0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10
}
f3 <- function(x) {x*0}

n<-200
sig2<-4
x0 <- rep(1:4,50)
x1 <- runif(n, 0, 1)
x2 <- runif(n, 0, 1)
x3 <- runif(n, 0, 1)
e <- rnorm(n, 0, sqrt(sig2))
y <- 2*x0 + f1(x1) + f2(x2) + f3(x3) + e
x0 <- factor(x0)
```

```

fit and plot...
b<-gam(y~x0+s(x1)+s(x2)+s(x3))
plot(b,pages=1,residuals=TRUE,all.terms=TRUE,shade=TRUE,shade.col=2)
plot(b,pages=1,seWithMean=TRUE) ## better coverage intervals
plot(b,pages=1,scale=0,scheme=2,deriv=TRUE) ## plot derivs of smooths

just parametric term alone...
termplot(b,terms="x0",se=TRUE)

more use of color...
op <- par(mfrow=c(2,2),bg="blue")
x <- 0:1000/1000
for (i in 1:3) {
 plot(b,select=i,rug=FALSE,col="green",
 col.axis="white",col.lab="white",all.terms=TRUE)
 for (j in 1:2) axis(j,col="white",labels=FALSE)
 box(col="white")
 eval(parse(text=paste("fx <- f",i,"(x)",sep="")))
 fx <- fx-mean(fx)
 lines(x,fx,col=2) ## overlay 'truth' in red
}
par(op)

example with 2-d plots, and use of schemes...
b1 <- gam(y~x0+s(x1,x2)+s(x3))
op <- par(mfrow=c(2,2))
plot(b1,all.terms=TRUE)
par(op)
op <- par(mfrow=c(2,2))
plot(b1,all.terms=TRUE,scheme=1)
par(op)
op <- par(mfrow=c(2,2))
plot(b1,all.terms=TRUE,scheme=c(2,1))
par(op)

3 and 4 D smooths can also be plotted
dat <- gamSim(1,n=400)
b1 <- gam(y~te(x0,x1,x2,d=c(1,2),k=c(5,15))+s(x3),data=dat)

Now plot. Use cex.lab and cex.axis to control axis label size,
n3 to control number of panels, n2 to control panel grid size,
scheme=1 to get greyscale...

plot(b1,pages=1)

```

---

polys.plot

---

*Plot geographic regions defined as polygons*

---

### Description

Produces plots of geographic regions defined by polygons, optionally filling the polygons with a color or grey shade dependent on a covariate.

**Usage**

```
polys.plot(pc,z=NULL,scheme="heat",lab="",...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pc     | A named list of matrices. Each matrix has two columns. The matrix rows each define the vertex of a boundary polygon. If a boundary is defined by several polygons, then each of these must be separated by an NA row in the matrix. See <a href="#">mrf</a> for an example. |
| z      | A vector of values associated with each area (item) of pc. If the vector elements have names then these are used to match elements of z to areas defined in pc. Otherwise pc and z are assumed to be in the same order. If z is NULL then polygons are not filled.          |
| scheme | One of "heat" or "grey", indicating how to fill the polygons in accordance with the value of z.                                                                                                                                                                             |
| lab    | label for plot.                                                                                                                                                                                                                                                             |
| ...    | other arguments to pass to plot (currently only if z is NULL).                                                                                                                                                                                                              |

**Details**

Any polygon within another polygon counts as a hole in the area. Further nesting is dealt with by treating any point that is interior to an odd number of polygons as being within the area, and all other points as being exterior. The routine is provided to facilitate plotting with models containing [mrf](#) smooths.

**Value**

Simply produces a plot.

```

predict.bam

*Prediction from fitted Big Additive Model model***Description**

In most cases essentially a wrapper for `predict.gam` for prediction from a model fitted by `bam`. Can compute on a parallel cluster. For models fitted using discrete methods with `discrete=TRUE` then discrete prediction methods are used instead.

Takes a fitted bam object produced by `bam` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R.

**Usage**

```
S3 method for class 'bam'
predict(object, newdata, type="link", se.fit=FALSE, terms=NULL,
 exclude=NULL, block.size=50000, newdata.guaranteed=FALSE,
 na.action=na.pass, cluster=NULL, discrete=TRUE, n.threads=1, gc.level=0, ...)
```

**Arguments**

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | a fitted bam object as produced by <code>bam</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| newdata | A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If newdata is provided then it should contain all the variables needed for prediction: a warning is generated if not.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| type    | When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When type="terms" each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. type="iterms" is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When type="response" predictions on the scale of the response are returned (possibly with approximate standard errors). When type="lpmatrix" then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case se.fit is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below). |
| se.fit  | when this is TRUE (not default) standard error estimates are returned for each prediction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| terms   | if type=="terms" or type="iterms" then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any terms not                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | named in this array will be set to zero. If NULL then all terms are included. "(Intercept)" is the intercept term.                                                                                                                                                                                                                                                                                                  |
| exclude            | if type=="terms" or type=="iterms" then terms (smooth or parametric) named in this array will not be returned. Otherwise any terms named in this array will be set to zero. If NULL then no terms are excluded. To avoid supplying covariate values for excluded smooth terms, set newdata.guaranteed=TRUE, but note that this skips all checks of newdata.                                                         |
| block.size         | maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive.                                                                                                                                                                                                                                                                                                 |
| newdata.guaranteed | Set to TRUE to turn off all checking of newdata except for sanity of factor levels: this can speed things up for large prediction tasks, but newdata must be complete, with no NA values for predictors required in the model.                                                                                                                                                                                      |
| na.action          | what to do about NA values in newdata. With the default na.pass, any row of newdata containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). na.exclude or na.omit result in the dropping of newdata rows, if they contain any NA values for required predictors. If newdata is missing then NA handling is determined from object\$na.action. |
| cluster            | predict.bam can compute in parallel using <a href="#">parLapply</a> from the <a href="#">parallel</a> package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code for <a href="#">bam</a> .                                                                                                                                  |
| discrete           | if TRUE then discrete prediction methods used with model fitted by discrete methods. FALSE for regular prediction. See details.                                                                                                                                                                                                                                                                                     |
| n.threads          | if se.fit=TRUE and discrete prediction is used then parallel computation can be used to speed up se calculation. This specifies number of hthreads to use.                                                                                                                                                                                                                                                          |
| gc.level           | increase from 0 to up the level of garbage collection if default does not give enough.                                                                                                                                                                                                                                                                                                                              |
| ...                | other arguments.                                                                                                                                                                                                                                                                                                                                                                                                    |

## Details

The standard errors produced by `predict.gam` are based on the Bayesian posterior covariance matrix of the parameters  $V_p$  in the fitted `bam` object.

To facilitate plotting with [termplot](#), if object possesses an attribute "para.only" and type=="terms" then only parametric terms of order 1 are returned (i.e. those that `termplot` can handle).

Note that, in common with other prediction functions, any offset supplied to [bam](#) as an argument is always ignored when predicting, unlike offsets specified in the `bam` model formula.

See the examples in [predict.gam](#) for how to use the `lpmatrix` for obtaining credible regions for quantities derived from the model.

When `discrete=TRUE` the prediction data in `newdata` is discretized in the same way as is done when using discrete fitting methods with `bam`. However the discretization grids are not currently identical to those used during fitting. Instead, discretization is done afresh for the prediction data. This means that if you are predicting for a relatively small set of prediction data, or on a regular grid, then the results may in fact be identical to those obtained without discretization. The disadvantage to this approach is that if you make predictions with a large data frame, and then split it into smaller data frames to make the predictions again, the results may differ slightly, because of slightly different discretization errors.

**Value**

If `type=="lpmatrix"` then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if `se.fit` is `TRUE` then a 2 item list is returned with items (both arrays) `fit` and `se.fit` containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether `type` is `"terms"` or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

`newdata` can be a data frame, list or `model.frame`: if it's a model frame then all variables must be supplied.

**WARNING**

Predictions are likely to be incorrect if data dependent transformations of the covariates are used within calls to smooths. See examples in [predict.gam](#).

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

## Description

Takes a fitted gam object produced by `gam()` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).

## Usage

```
S3 method for class 'gam'
predict(object,newdata,type="link",se.fit=FALSE,terms=NULL,
 exclude=NULL,block.size=NULL,newdata.guaranteed=FALSE,
 na.action=na.pass,unconditional=FALSE,iterms.type=NULL,...)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <code>object</code>  | a fitted gam object as produced by <code>gam()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>newdata</code> | A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If <code>newdata</code> is provided then it should contain all the variables needed for prediction: a warning is generated if not. See details for use with <code>link{linear.functional.terms}</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>type</code>    | When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When <code>type="terms"</code> each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. <code>type="iterms"</code> is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When <code>type="response"</code> predictions on the scale of the response are returned (possibly with approximate standard errors). When <code>type="lpmatrix"</code> then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case <code>se.fit</code> is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below). |
| <code>se.fit</code>  | when this is TRUE (not default) standard error estimates are returned for each prediction. If set to a number between 0 and 1 then this is taken as the confidence level for intervals that are returned instead.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>terms</code>   | if <code>type=="terms"</code> or <code>type="iterms"</code> then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any terms not named in this array will be set to zero. If NULL then all terms are included.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>exclude</code> | if <code>type=="terms"</code> or <code>type="iterms"</code> then terms (smooth or parametric) named in this array will not be returned. Otherwise any terms named in this array will be set to zero. If NULL then no terms are excluded. Note that this is the term names as it appears in the model summary, see example. You can avoid providing the covariates for excluded smooth terms by setting <code>newdata.guaranteed=TRUE</code> ,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 | which will avoid all checks on newdata (covariates for parametric terms can not be skipped).                                                                                                                                                                                                                                                                                                                                                                              |
| <code>block.size</code>         | maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive. Set to $< 1$ to use total number of predictions as this. If NULL then block size is 1000 if new data supplied, and the number of rows in the model frame otherwise.                                                                                                                                                                                   |
| <code>newdata.guaranteed</code> | Set to TRUE to turn off all checking of newdata except for sanity of factor levels: this can speed things up for large prediction tasks, but newdata must be complete, with no NA values for predictors required in the model.                                                                                                                                                                                                                                            |
| <code>na.action</code>          | what to do about NA values in newdata. With the default <code>na.pass</code> , any row of newdata containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). <code>na.exclude</code> or <code>na.omit</code> result in the dropping of newdata rows, if they contain any NA values for required predictors. If newdata is missing then NA handling is determined from <code>object\$na.action</code> . |
| <code>unconditional</code>      | if TRUE then the smoothing parameter uncertainty corrected covariance matrix is used, when available, otherwise the covariance matrix conditional on the estimated smoothing parameters is used.                                                                                                                                                                                                                                                                          |
| <code>iterms.type</code>        | if <code>type="iterms"</code> then standard errors can either include the uncertainty in the overall mean (default, with fixed and random effects included) or the uncertainty in the mean of the non-smooth fixed effects only ( <code>iterms.type=2</code> ).                                                                                                                                                                                                           |
| <code>...</code>                | other arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

The standard errors produced by `predict.gam` are based on the Bayesian posterior covariance matrix of the parameters  $V_p$  in the fitted gam object.

When predicting from models with [linear.functional.terms](#) then there are two possibilities. If the summation convention is to be used in prediction, as it was in fitting, then newdata should be a list, with named matrix arguments corresponding to any variables that were matrices in fitting. Alternatively one might choose to simply evaluate the constituent smooths at particular values in which case arguments that were matrices can be replaced by vectors (and newdata can be a dataframe). See [linear.functional.terms](#) for example code.

To facilitate plotting with [termplot](#), if object possesses an attribute "para.only" and `type=="terms"` then only parametric terms of order 1 are returned (i.e. those that `termplot` can handle).

Note that, in common with other prediction functions, any offset supplied to [gam](#) as an argument is always ignored when predicting, unlike offsets specified in the gam model formula.

See the examples for how to use the `lpmatrix` for obtaining credible regions for quantities derived from the model.

## Value

If `type=="lpmatrix"` then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if `se.fit` is TRUE then a 2 item list is returned with items (both arrays) `fit` and `se.fit` containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether `type` is "terms" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array

is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept. If `se.fit` is a number between 0 and 1 then in place of `se.fit` two arrays are returned `ll` and `ul` giving the confidence interval limits.

`newdata` can be a data frame, list or `model.frame`: if it's a model frame then all variables must be supplied.

## WARNING

Predictions are likely to be incorrect if data dependent transformations of the covariates are used within calls to smooths. See examples.

Note that the behaviour of this function is not identical to `predict.gam()` in `SpluS`.

`type="terms"` does not exactly match what `predict.lm` does for parametric model components.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

The design is inspired by the `S` function of the same name described in Chambers and Hastie (1993) (but is not a clone).

---

Predict.matrix

---

*Prediction methods for smooth terms in a GAM*

---

## Description

Takes smooth objects produced by smooth.construct methods and obtains the matrix mapping the parameters associated with such a smooth to the predicted values of the smooth at a set of new covariate values.

In practice this method is often called via the wrapper function [PredictMat](#).

## Usage

```

Predict.matrix(object,data)
Predict.matrix2(object,data)

```

## Arguments

**object** is a smooth object produced by a smooth.construct method function. The object contains all the information required to specify the basis for a term of its

class, and this information is used by the appropriate `Predict.matrix` function to produce a prediction matrix for new covariate values. Further details are given in [smooth.construct](#).

**data** A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for [smooth.construct](#) and `smooth.construct2`.

.

### Details

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. The `Predict.matrix` functions are used to obtain the matrix that will map the parameters associated with a smooth term to the predicted values for the term at new covariate values.

Note that new smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function: see the example code provided for [smooth.construct](#) for details.

### Value

A matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in object. If the smooth class is one which generates offsets the corresponding offset is returned as attribute "offset" of the matrix.

See smooth.construct examples
```

---

Predict.matrix.cr.smooth

*Predict matrix method functions*

---

### Description

The various built in smooth classes for use with [gam](#) have associate `Predict.matrix` method functions to enable prediction from the fitted model.

**Usage**

```
S3 method for class 'cr.smooth'
Predict.matrix(object, data)
S3 method for class 'cs.smooth'
Predict.matrix(object, data)
S3 method for class 'cyclic.smooth'
Predict.matrix(object, data)
S3 method for class 'pspline.smooth'
Predict.matrix(object, data)
S3 method for class 'tensor.smooth'
Predict.matrix(object, data)
S3 method for class 'tprs.smooth'
Predict.matrix(object, data)
S3 method for class 'ts.smooth'
Predict.matrix(object, data)
S3 method for class 't2.smooth'
Predict.matrix(object, data)
```

**Arguments**

|        |                                                                                                                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | a smooth object, usually generated by a <a href="#">smooth.construct</a> method having processed a smooth specification object generated by an <a href="#">s</a> or <a href="#">te</a> term in a <a href="#">gam</a> formula. |
| data   | A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for <a href="#">smooth.construct</a> and <a href="#">smooth.construct2</a>                |
| .      |                                                                                                                                                                                                                               |

**Details**

The Predict matrix function is not normally called directly, but is rather used internally by [predict.gam](#) etc. to predict from a fitted [gam](#) model. See [Predict.matrix](#) for more details, or the specific [smooth.construct](#) pages for details on a particular smooth class.

**Value**

A matrix mapping the coefficients for the smooth term to its values at the supplied data values.

**Author(s)**

```

---

`Predict.matrix.soap.film`*Prediction matrix for soap film smooth*

---

## Description

Creates a prediction matrix for a soap film smooth object, mapping the coefficients of the smooth to the linear predictor component for the smooth. This is the `Predict.matrix` method function required by [gam](#).

## Usage

```
S3 method for class 'soap.film'
Predict.matrix(object,data)
S3 method for class 'sf.wiggly'
Predict.matrix(object,data)
S3 method for class 'sf.film'
Predict.matrix(object,data)
```

## Arguments

|                     |                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------|
| <code>object</code> | A class "soap.film", "sf.wiggly" or "sf.film" object.                                               |
| <code>data</code>   | A list list or data frame containing the arguments of the smooth at which predictions are required. |

## Details

The smooth object will be largely what is returned from `smooth.construct.so.smooth.spec`, although elements X and S are not needed, and need not be present, of course.

## Value

A matrix. This may have an "offset" attribute corresponding to the contribution from any known boundary conditions on the smooth.

## See Also

---

print.gam

---

*Print a Generalized Additive Model object.*

---

## Description

The default print method for a gam object.

## Usage

```
S3 method for class 'gam'
print(x, ...)
```

## Arguments

x, ...                      fitted model objects of class gam as produced by gam().

## Details

Prints out the family, model formula, effective degrees of freedom for each smooth term, and optimized value of the smoothness selection criterion used. See [gamObject](#) (or names(x)) for a listing of what the object contains. [summary.gam](#) provides more detail.

Note that the optimized smoothing parameter selection criterion reported is one of GCV, UBRE(AIC), GACV, negative log marginal likelihood (ML), or negative log restricted likelihood (REML).

If rank deficiency of the model was detected then the apparent rank is reported, along with the length of the coefficient vector (rank in absense of rank deficieny). Rank deficiency occurs when not all coefficients are identifiable given the data. Although the fitting routines (except gamm) deal gracefully with rank deficiency, interpretation of rank deficient models may be difficult.

psum.chisq

*Evaluate the c.d.f. of a weighted sum of chi-squared deviates***Description**

Evaluates the c.d.f. of a weighted sum of chi-squared random variables by the method of Davies (1973, 1980). That is it computes

$$P(q < \sum_{i=1}^r \lambda_i X_i + \sigma_z Z)$$

where  $X_j$  is a chi-squared random variable with `df[j]` (integer) degrees of freedom and non-centrality parameter `nc[j]`, while  $Z$  is a standard normal deviate.

**Usage**

```
psum.chisq(q, lb, df=rep(1, length(lb)), nc=rep(0, length(lb)), sigz=0,
 lower.tail=FALSE, tol=2e-5, nlim=100000, trace=FALSE)
```

**Arguments**

|                         |                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------|
| <code>q</code>          | is the vector of quantile values at which to evaluate.                                       |
| <code>lb</code>         | contains $\lambda_i$ , the weight for deviate $i$ . Weights can be positive and/or negative. |
| <code>df</code>         | is the integer vector of chi-squared degrees of freedom.                                     |
| <code>nc</code>         | is the vector of non-centrality parameters for the chi-squared deviates.                     |
| <code>sigz</code>       | is the multiplier for the standard normal deviate. Non- positive to exclude this term.       |
| <code>lower.tail</code> | indicates whether lower of upper tail probabilities are required.                            |
| <code>tol</code>        | is the numerical tolerance to work to.                                                       |
| <code>nlim</code>       | is the maximum number of integration steps to allow                                          |
| <code>trace</code>      | can be set to TRUE to return some trace information and a fault code as attributes.          |

**Details**

This calls a C translation of the original Algol60 code from Davies (1980), which numerically inverts the characteristic function of the distribution (see Davies, 1973). Some modifications have been made to remove goto statements and global variables, to use a slightly more efficient sorting of `lb` and to use R functions for  $\log(1+x)$ . In addition the integral and associated error are accumulated in single terms, rather than each being split into 2, since only their sums are ever used. If `q` is a vector then `psum.chisq` calls the algorithm separately for each `q[i]`.

If the Davies algorithm returns an error then an attempt will be made to use the approximation of Liu et al (2009) and a warning will be issued. If that is not possible then an NA is returned. A warning will also be issued if the algorithm detects that round off errors may be significant.

If `trace` is set to TRUE then the result will have two attributes. "`ifault`" is 0 for no problem, 1 if the desired accuracy can not be obtained, 2 if round-off error may be significant, 3 is invalid parameters have been supplied or 4 if integration parameters can not be located. "`trace`" is a 7 element vector: 1. absolute value sum; 2. total number of integration terms; 3. number of integrations; 4. integration interval in main integration; 5. truncation point in initial integration; 6. sd of convergence factor term; 7. number of cycles to locate integration parameters. See Davies (1980) for more details. Note that for vector `q` these attributes relate to the final element of `q`.

 qq.gam

*QQ plots for gam model residuals*

---

**Description**

Takes a fitted gam object produced by `gam()` and produces QQ plots of its residuals (conditional on the fitted model coefficients and scale parameter). If the model distributional assumptions are met then usually these plots should be close to a straight line (although discrete data can yield marked random departures from this line).

**Usage**

```
qq.gam(object, rep=0, level=.9,s.rep=10,
 type=c("deviance","pearson","response"),
 pch=".", rl.col=2, rep.col="gray80", ...)
```

## Arguments

|                      |                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | a fitted gam object as produced by <code>gam()</code> (or a <code>glm</code> object).                                                                                                                                       |
| <code>rep</code>     | How many replicate datasets to generate to simulate quantiles of the residual distribution. 0 results in an efficient simulation free method for direct calculation, if this is possible for the object family.             |
| <code>level</code>   | If simulation is used for the quantiles, then reference intervals can be provided for the QQ-plot, this specifies the level. 0 or less for no intervals, 1 or more to simply plot the QQ plot for each replicate generated. |
| <code>s.rep</code>   | how many times to randomize uniform quantiles to data under direct computation.                                                                                                                                             |
| <code>type</code>    | what sort of residuals should be plotted? See <a href="#">residuals.gam</a> .                                                                                                                                               |
| <code>pch</code>     | plot character to use. 19 is good.                                                                                                                                                                                          |
| <code>rl.col</code>  | color for the reference line on the plot.                                                                                                                                                                                   |
| <code>rep.col</code> | color for reference bands or replicate reference plots.                                                                                                                                                                     |
| <code>...</code>     | extra graphics parameters to pass to plotting functions.                                                                                                                                                                    |

## Details

QQ-plots of the the model residuals can be produced in one of two ways. The cheapest method generates reference quantiles by associating a quantile of the uniform distribution with each datum, and feeding these uniform quantiles into the quantile function associated with each datum. The resulting quantiles are then used in place of each datum to generate approximate quantiles of residuals. The residual quantiles are averaged over `s.rep` randomizations of the uniform quantiles to data.

The second method is to use direct simulation. For each replicate, data are simulated from the fitted model, and the corresponding residuals computed. This is repeated `rep` times. Quantiles are readily obtained from the empirical distribution of residuals so obtained. From this method reference bands are also computable.

Even if `rep` is set to zero, the routine will attempt to simulate quantiles if no quantile function is available for the family. If no random deviate generating function family is available (e.g. for the quasi families), then a normal QQ-plot is produced. The routine conditions on the fitted model coefficients and the scale parameter estimate.

The plots are very similar to those proposed in Ben and Yohai (2004), but are substantially cheaper to produce (the interpretation of residuals for binary data in Ben and Yohai is not recommended).

Note that plots for raw residuals from fits to binary data contain almost no useful information about model fit. Whether the residual is negative or positive is decided by whether the response is zero or one. The magnitude of the residual, given its sign, is determined entirely by the fitted values. In consequence only the most gross violations of the model are detectable from QQ-plots of residuals for binary data. To really check distributional assumptions from residuals for binary data you have to be able to group the data somehow. Binomial models other than binary are ok.

plot(b,residuals=TRUE,pch=19,cex=.3)
```

random.effects

*Random effects in GAMs*

## Description

The smooth components of GAMs can be viewed as random effects for estimation purposes. This means that more conventional random effects terms can be incorporated into GAMs in two ways. The first method converts all the smooths into fixed and random components suitable for estimation by standard mixed modelling software. Once the GAM is in this form then conventional random effects are easily added, and the whole model is estimated as a general mixed model. [gamm](#) and [gamm4](#) from the [gamm4](#) package operate in this way.

The second method represents the conventional random effects in a GAM in the same way that the smooths are represented — as penalized regression terms. This method can be used with [gam](#) by making use of `s(...,bs="re")` terms in a model: see [smooth.construct.re.smooth.spec](#), for full details. The basic idea is that, e.g., `s(x,z,g,bs="re")` generates an i.i.d. Gaussian random effect with model matrix given by `model.matrix(~x:z:g-1)` — in principle such terms can take any number of arguments. This simple approach is sufficient for implementing a wide range of commonly used random effect structures. For example if `g` is a factor then `s(g,bs="re")` produces a random coefficient for each level of `g`, with the random coefficients all modelled as i.i.d. normal. If `g` is a factor and `x` is numeric, then `s(x,g,bs="re")` produces an i.i.d. normal random slope relating the response to `x` for each level of `g`. If `h` is another factor then `s(h,g,bs="re")` produces the usual i.i.d. normal `g - h` interaction. Note that a rather useful approximate test for zero random effect is also implemented for such terms based on Wood (2013). If the precision matrix is known to within a multiplicative constant, then this can be supplied via the `xt` argument of `s`. See [smooth.construct.re.smooth.spec](#) for details and example. Some models require differences between different levels of the same random effect: these can be implemented as described in [linear.functional.terms](#).

Alternatively, but less straightforwardly, the `paraPen` argument to [gam](#) can be used: see [gam.models](#).

If smoothing parameter estimation is by ML or REML (e.g. `gam(...,method="REML")`) then this approach is a completely conventional likelihood based treatment of random effects, using a full Laplace approximation to the (restricted) marginal likelihood. However note that MAP estimates of the model coefficients are returned. For the fixed effects in non-Gaussian cases, these are only approximately the MLEs (with the random effects integrated out), and the difference can be large in some circumstances.

`gam` can be slow for fitting models with large numbers of random effects, because it does not exploit the sparsity that is often a feature of parametric random effects. It can not be used for models with more coefficients than data. However `gam` is often faster and more reliable than `gamm` or `gamm4`, when the number of random effects is modest.

To facilitate the use of random effects with `gam`, [gam.vcomp](#) is a utility routine for converting smoothing parameters to variance components. It also provides confidence intervals, if smoothness estimation is by ML or REML.

Note that treating random effects as smooths does not remove the usual problems associated with testing variance components for equality to zero: see [summary.gam](#) and [anova.gam](#).

residuals.gam

*Generalized Additive Model residuals***Description**

Returns residuals for a fitted gam model object. Pearson, deviance, working and response residuals are available.

**Usage**

```
S3 method for class 'gam'
residuals(object, type = "deviance",...)
```

**Arguments**

|        |                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------|
| object | a gam fitted model object.                                                                                      |
| type   | the type of residuals wanted. Usually one of "deviance", "pearson", "scaled.pearson", "working", or "response". |
| ...    | other arguments.                                                                                                |

**Details**

Response residuals are the raw residuals (data minus fitted values). Scaled Pearson residuals are raw residuals divided by the standard deviation of the data according to the model mean variance relationship and estimated scale parameter. Pearson residuals are the same, but multiplied by the square root of the scale parameter (so they are independent of the scale parameter):  $((y - \mu) / \sqrt{V(\mu)})$ , where  $y$  is data  $\mu$  is model fitted value and  $V$  is model mean-variance relationship.). Both are provided since not all texts agree on the definition of Pearson residuals. Deviance residuals simply return the deviance residuals defined by the model family. Working residuals are the residuals returned from model fitting at convergence.

Families can supply their own residual function, which is used in place of the standard function if present, (e.g. [cox.ph](#)).

**Value**

A vector of residuals.

rig

---

*Generate inverse Gaussian random deviates*

---

**Description**

Generates inverse Gaussian random deviates.

**Usage**

```
rig(n, mean, scale)
```

**Arguments**

|       |                                                                                                                      |
|-------|----------------------------------------------------------------------------------------------------------------------|
| n     | the number of deviates required. If this has length > 1 then the length is taken as the number of deviates required. |
| mean  | vector of mean values.                                                                                               |
| scale | vector of scale parameter values (lambda, see below)                                                                 |

**Details**

If  $x$  is the returned vector, then  $E(x) = \text{mean}$  while  $\text{var}(x) = \text{scale} * \text{mean}^3$ . For density and distribution functions see the `statmod` package. The algorithm used is Algorithm 5.7 of Gentle (2003), based on Michael et al. (1976). Note that `scale` here is the scale parameter in the GLM sense, which is the reciprocal of the usual ‘lambda’ parameter.

**Value**

A vector of inverse Gaussian random deviates.

*Generate from or evaluate multivariate normal or t densities.***Description**

Generates multivariate normal or t random deviates, and evaluates the corresponding log densities.

**Usage**

```

rmvn(n,mu,V)
r.mvt(n,mu,V,df)
dmvn(x,mu,V,R=NULL)
d.mvt(x,mu,V,df,R=NULL)

```

**Arguments**

|    |                                                                                                         |
|----|---------------------------------------------------------------------------------------------------------|
| n  | number of simulated vectors required.                                                                   |
| mu | the mean of the vectors: either a single vector of length $p = \text{ncol}(V)$ or an $n$ by $p$ matrix. |
| V  | A positive semi definite covariance matrix.                                                             |
| df | The degrees of freedom for a t distribution.                                                            |
| x  | A vector or matrix to evaluate the log density of.                                                      |
| R  | An optional Cholesky factor of V (not pivoted).                                                         |

**Details**

Uses a ‘square root’ of V to transform standard normal deviates to multivariate normal with the correct covariance matrix.

**Value**

An  $n$  row matrix, with each row being a draw from a multivariate normal or t density with covariance matrix V and mean vector mu. Alternatively each row may have a different mean vector if mu is a vector.

For density functions, a vector of log densities.

**Examples**

```
library(mgcv)
V <- matrix(c(2,1,1,2),2,2)
mu <- c(1,3)
n <- 1000
z <- rmvn(n,mu,V)
crossprod(sweep(z,2,colMeans(z)))/n ## observed covariance matrix
colMeans(z) ## observed mu
dmvn(z,mu,V)
```

Rrank

*Find rank of upper triangular matrix***Description**

Finds rank of upper triangular matrix R, by estimating condition number of upper rank by rank block, and reducing rank until this is acceptably low. Assumes R has been computed by a method that uses pivoting, usually pivoted QR or Choleski.

**Usage**

```
Rrank(R,tol=.Machine$double.eps^.9)
```

**Arguments**

|     |                                                                         |
|-----|-------------------------------------------------------------------------|
| R   | An upper triangular matrix, obtained by pivoted QR or pivoted Choleski. |
| tol | the tolerance to use for judging rank.                                  |

**Details**

The method is based on Cline et al. (1979) as described in Golub and van Loan (1996).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

Cline, A.K., C.B. Moler, G.W. Stewart and J.H. Wilkinson (1979) An estimate for the condition number of a matrix. SIAM J. Num. Anal. 16, 368-375

Golub, G.H, and C.F. van Loan (1996) Matrix Computations 3rd ed. Johns Hopkins University Press, Baltimore.

**Examples**

```
set.seed(0)
n <- 10;p <- 5
x <- runif(n*(p-1))
X <- matrix(c(x,x[1:n]),n,p)
qrx <- qr(X,LAPACK=TRUE)
Rrank(qr.R(qrx))
```

rTweedie

*Generate Tweedie random deviates***Description**

Generates Tweedie random deviates, for powers between 1 and 2.

**Usage**

```
rTweedie(mu,p=1.5,phi=1)
```

**Arguments**

|     |                                                                                                                                                                |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mu  | vector of expected values for the deviates to be generated. One deviate generated for each element of mu.                                                      |
| p   | the variance of a deviate is proportional to its mean, mu to the power p. p must be between 1 and 2. 1 is Poisson like (exactly Poisson if phi=1), 2 is gamma. |
| phi | The scale parameter. Variance of the deviates is given by $\phi \cdot \mu^p$ .                                                                                 |

**Details**

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution, with mean  $\mu^{(2-p)/((2-p)\phi)}$ . The Gamma random variables that are summed have shape parameter  $(2-p)/(p-1)$  and scale parameter  $\phi \cdot (p-1) \cdot \mu^{(p-1)}$  (note that this scale parameter is different from the scale parameter for a GLM with Gamma errors).

This is a restricted, but faster, version of `rtweedie` from the `tweedie` package.

**Value**

A vector of random deviates from a Tweedie distribution, expected value vector mu, variance vector  $\phi \cdot \mu^p$ .

## Examples

```
library(mgcv)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
n <- 300
x <- runif(n)
mu <- exp(f2(x)/3+1.1); x <- x*10 - 4
y <- rTweedie(mu,p=1.5,phi=1.3)
b <- gam(y~s(x,k=20),family=Tweedie(p=1.5))
b
plot(b)
```

s

*Defining smooths in GAM formulae*

## Description

Function used in definition of smooth terms within gam model formulae. The function does not evaluate a (spline) smooth - it exists purely to help set up a model using spline based smooths.

## Usage

```
s(..., k=-1, fx=FALSE, bs="tp", m=NA, by=NA, xt=NULL, id=NULL, sp=NULL, pc=NULL)
```

## Arguments

- |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ... | a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. <code>s(log(x))</code> is fine, but <code>s(I(x/sd(x)))</code> is not (see <a href="#">predict.gam</a> ).                                                                                                                                                                                                  |
| k   | the dimension of the basis used to represent the smooth term. The default depends on the number of variables that the smooth is a function of. <code>k</code> should not be less than the dimension of the null space of the penalty for the term (see <a href="#">null.space.dimension</a> ), but will be reset if it is. See <a href="#">choose.k</a> for further information.                                                                                                   |
| fx  | indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).                                                                                                                                                                                                                                                                                                                                                                      |
| bs  | a two letter character string indicating the (penalized) smoothing basis to use. (eg "tp" for thin plate regression spline, "cr" for cubic regression spline). see <a href="#">smooth.terms</a> for an over view of what is available.                                                                                                                                                                                                                                             |
| m   | The order of the penalty for this term (e.g. 2 for normal cubic spline penalty with 2nd derivatives when using default t.p.s basis). NA signals autoinitialization. Only some smooth classes use this. The "ps" class can use a 2 item array giving the basis and penalty order separately.                                                                                                                                                                                        |
| by  | a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth, evaluated at the corresponding covariate values (a 'varying coefficient model' results). For the numeric by variable case the resulting smooth is not usually subject to a centering constraint (so the by variable should not be added as an additional main effect). In the factor by variable case a replicate of the smooth is produced for |

each factor level (these smooths will be centered, so the factor usually needs to be added as a main effect as well). See [gam.models](#) for further details. A by variable may also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see [gam.models](#) and [linear.functional.terms](#) for details).

|    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xt | Any extra information required to set up a particular basis. Used e.g. to set large data set handling behaviour for "tp" basis. If <code>xt\$sumConv</code> exists and is <code>FALSE</code> then the summation convention for matrix arguments is turned off.                                                                                                                                                                                                             |
| id | A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more terms have the same <code>id</code> then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction). An <code>id</code> with a factor by variable causes the smooths at each factor level to have the same smoothing parameter. |
| sp | any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in <code>sp</code> argument to <a href="#">gam</a> . Ignored by <a href="#">gamm</a> .                                                                                                        |
| pc | If not <code>NULL</code> , signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied as a number. See <a href="#">identifiability</a> . Can also be supplied as a list of lists to specify general linear constraints as described in <a href="#">scasm</a> - ignored by other modelling routines.                                             |

## Details

The function does not evaluate the variable arguments. To use this function to specify use of your own smooths, note the relationships between the inputs and the output object and see the example in [smooth.construct](#).

## Value

A class `xx.smooth.spec` object, where `xx` is a basis identifying code given by the `bs` argument of `s`. These `smooth.spec` objects define smooths and are turned into bases and penalties by `smooth.construct` method functions.

The returned object contains the following items:

|         |                                                                                                                                                                                        |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| term    | An array of text strings giving the names of the covariates that the term is a function of.                                                                                            |
| bs.dim  | The dimension of the basis used to represent the smooth.                                                                                                                               |
| fixed   | <code>TRUE</code> if the term is to be treated as a pure regression spline (with fixed degrees of freedom); <code>FALSE</code> if it is to be treated as a penalized regression spline |
| dim     | The dimension of the smoother - i.e. the number of covariates that it is a function of.                                                                                                |
| p.order | The order of the t.p.r.s. penalty, or 0 for auto-selection of the penalty order.                                                                                                       |
| by      | is the name of any by variable as text (" <code>NA</code> " for none).                                                                                                                 |
| label   | A suitable text label for this smooth term.                                                                                                                                            |
| xt      | The object passed in as argument <code>xt</code> .                                                                                                                                     |

|    |                                                                                                              |
|----|--------------------------------------------------------------------------------------------------------------|
| id | An identifying label or number for the smooth, linking it to other smooths. Defaults to NULL for no linkage. |
| sp | array of smoothing parameters for the term (negative for auto-estimation). Defaults to NULL.                 |

scasm

---

*Shape constrained additive smooth models*

---

**Description**

Fits a generalized additive model (GAM, GAMM, GAMLSS) subject to shape constraints on the components, using quadratic and linear programming and the extended Fellner-Schall method for smoothness estimation. Usable with all the families listed in [family.mgcv](#).

**Usage**

```
scasm(formula,family=gaussian(),data=list(),weights=NULL,subset=NULL,
 na.action, offset=NULL,control=list(),scale=0,select=FALSE,
 knots=NULL,sp=NULL,gamma=1,fit=TRUE,G=NULL,drop.unused.levels=TRUE,
 drop.intercept=NULL,bs=0,...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | A GAM formula, or a list of formulae (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). These are exactly like the formula for a GLM except that smooth terms, <a href="#">s</a> , <a href="#">te</a> , <a href="#">ti</a> and <a href="#">t2</a> , can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).                      |
| family    | This is a family object specifying the distribution and link to use in fitting etc (see <a href="#">glm</a> and <a href="#">family</a> ). See <a href="#">family.mgcv</a> for a full list of what is available, which goes well beyond exponential family. Note that quasi families actually result in the use of extended quasi-likelihood if method is set to a RE/ML method (McCullagh and Nelder, 1989, 9.6).                                  |
| data      | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>gam</code> is called.                                                                                                                                                                                                   |
| weights   | prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to reweight the contributions of each datum without changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. <code>weights &lt;- weights/mean(weights)</code> ).                                                  |
| subset    | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                          |
| na.action | a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.                                                                                                                                                                                                                                |
| offset    | Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula (this used to conform to the behaviour of <code>lm</code> and <code>glm</code> ).                                                                                                                                                                                           |
| control   | A list of fit control parameters to replace defaults returned by <a href="#">gam.control</a> . Any control parameters not supplied stay at their default values.                                                                                                                                                                                                                                                                                   |
| select    | Should selection penalties be added to the smooth effects, so that they can in principle be penalized out of the model? See <code>gamma</code> to increase penalization. Has the side effect that smooths no longer have a fixed effect component (improper prior from a Bayesian perspective) allowing REML comparison of models with the same fixed effect structure.                                                                            |
| scale     | If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.                                                                                                                                 |
| gamma     | Increase above 1 to force smoother fits. <code>gamma</code> is used to multiply the effective degrees of freedom in the GCV/UBRE/AIC score (so $\log(n)/2$ is BIC like). $n/\text{gamma}$ can be viewed as an effective sample size, which allows it to play a similar role for RE/ML smoothing parameter estimation.                                                                                                                              |
| knots     | this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the <code>k</code> value supplied (note that the number of knots is not always just <code>k</code> ). See <a href="#">tprs</a> for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate. |
| sp        | A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula.                                                                                                                                                                                                                                                                                       |

Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then `length(sp)` must correspond to the number of underlying smoothing parameters. Note that `discrete=TRUE` may result in re-ordering of variables in tensor product smooths for improved efficiency, and `sp` must be supplied in re-ordered order.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>drop.unused.levels</code> | by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.                                                                                                                                                                                                                                                              |
| <code>G</code>                  | if not <code>NULL</code> then this should be the object returned by a previous call to <code>bam</code> with <code>fit=FALSE</code> . Causes all other arguments to be ignored except <code>sp</code> , <code>chunk.size</code> , <code>gamma</code> , <code>nthreads</code> , <code>cluster</code> , <code>rho</code> , <code>gc.level</code> , <code>samfrac</code> , <code>use.chol</code> , <code>method</code> and <code>scale</code> (if $>0$ ). |
| <code>fit</code>                | if <code>FALSE</code> then the model is set up for fitting but not estimated, and an object is returned, suitable for passing as the <code>G</code> argument to <code>bam</code> .                                                                                                                                                                                                                                                                     |
| <code>drop.intercept</code>     | Set to <code>TRUE</code> to force the model to really not have the a constant in the parametric model part, even with factor variables present.                                                                                                                                                                                                                                                                                                        |
| <code>bs</code>                 | number of bootstrap replicates to use to approximate sampling distribution of model coefficients. If not zero or <code>FALSE</code> then results in a matrix <code>bs</code> being returned in the fit object, whose columns are the bootstrap replicate coefficients.                                                                                                                                                                                 |
| <code>...</code>                | further arguments for passing on e.g. to <code>gam.fit</code> (such as <code>mustart</code> ).                                                                                                                                                                                                                                                                                                                                                         |

## Details

Operates much as [gam](#), but allows linear constraints on smooths to facilitate shape constraints. Smoothness selection uses the extended Fellner-Schall method of Wood and Fasiolo (2017). Model coefficient estimation uses linear programming to find initial feasible coefficients, and then sequential quadratic programming to maximize the penalized likelihood given smoothing parameters.

For simple shape constraints on univariate smooths (and hence tensor product smooths) see [smooth.construct.sc.smooth.spec](#). General linear constraints can be imposed on any smooth term via the `pc` argument to `s` etc. To do this `pc` is provided as a list of two lists. The first list component specifies the linear inequality constraints, and the second, if present specifies linear equality constraints.

The first list has a matrix element for each covariate of the smooth, named as the covariates. Two further elements are un-named: a matrix of weights and a vector specifying the right hand side of the condition to be met. For example, suppose that a constraint is to be applied to a smooth term  $f(X, Z)$ . The list would contain named matrices **X** and **Z** and a third unnamed matrix, **W**, say. All are of the same dimension. The list also contains an unnamed vector with the same number of rows as the matrices, **b**, say. The constraints encoded are

$$\sum_j f(X_{ij}, Z_{ij}) W_{ij} > b_i$$

where the summation is over all columns of the matrices. There is one constraint for each row of the **b**. The second list, if present, has the same structure, but encodes equality constraints. If the first list is empty then there are no inequality constraints.

Notice that this structure is quite general - derivative and integral constraints are easily implemented numerically. Also note that the simple constraints of [smooth.construct.sc.smooth.spec](#) can be combined with general `pc` constraints.

**Value**

An object of class "gam" as described in [gamObject](#).

**WARNINGS**

This is generally slower than gam, and can only use EFS soothness estimation

**Examples**

```
library(mgcv)
a density estimation example, illustrating general constraint use...
n <- 400; set.seed(4)
x <- c(rnorm(n*.8,.4,.13),runif(n*.2))
y <- rep(1e-10,n)
xp=(1:n-.5)/n
options(warn=-1)
Use an exponential distribution, inverse link and zero pseudoresponse
data to get correct likelihood. Use a positive smooth and impose
integration to 1 via a general linear 'pc' constraint...
b <- scasm(y ~ s(x,bs="sc",xt="+",k=15,pc=list(list(x=matrix(xp,1,n),
 matrix(1/n,1,n),1))),-1, family=Gamma,scale=1,knots=list(x=c(0,1)))
options(warn=0)
plot(b,scheme=2)
lines(xp,.2+dnorm(xp,.4,.13)*.8,col=2)

some more standard examples

fs <- function(x,k) { ## some simulation functions
 if (k==2) 0.2*x^11*(10*(1-x))^6 + 10*(10*x)^3*(1-x)^10 else
 if (k==0) 2 * sin(pi * x) else
 if (k==1) exp(2 * x) else
 if (k==3) exp((x-.4)*20)/(1+exp((x-.4)*20)) else
 if (k==4) (x-.55)^4 else x
} ## fs

Simple Poisson example...
n <- 400; set.seed(4)
x0 <- runif(n); x1 <- runif(n); x2 <- runif(n); x3 <- runif(n);
fac <- factor(sample(1:40,n,replace=TRUE))
f <- fs(x0,k=0) + 2*fs(x1,k=3) + fs(x2,k=2) + 10*fs(x3,k=4)
mu <- exp((f-1)/4)
```

```

y <- rpois(n,mu)
k <- 10
b0 <- gam(y~s(x0,bs="bs",k=k)+s(x1,bs="bs",k=k)+s(x2,bs="bs",k=k)+

scat

*GAM scaled t family for heavy tailed data*

## Description

Family for use with [gam](#) or [bam](#), implementing regression for the heavy tailed response variables,  $y$ , using a scaled  $t$  model. The idea is that  $(y - \mu)/\sigma \sim t_\nu$  where  $\mu$  is determined by a linear predictor, while  $\sigma$  and  $\nu$  are parameters to be estimated alongside the smoothing parameters.

## Usage

```
scat(theta = NULL, link = "identity",min.df=3)
```

## Arguments

|        |                                                                                                                                                                                                                                                                      |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| theta  | the parameters to be estimated $\nu = b + \exp(\theta_1)$ (where 'b' is min.df) and $\sigma = \exp(\theta_2)$ . If supplied and both positive, then taken to be fixed values of $\nu$ and $\sigma$ . If any negative, then absolute values taken as starting values. |
| link   | The link function: one of "identity", "log" or "inverse".                                                                                                                                                                                                            |
| min.df | minimum degrees of freedom. Should not be set to 2 or less as this implies infinite response variance.                                                                                                                                                               |

## Details

Useful in place of Gaussian, when data are heavy tailed. min.df can be modified, but lower values can occasionally lead to convergence problems in smoothing parameter estimation. In any case min.df should be >2, since only then does a  $t$  random variable have finite variance.

## Value

An object of class `extended.family`.

**Author(s)**

Natalya Pya (nat.pya@gmail.com)

**References**

**Examples**

```
library(mgcv)
Simulate some t data...
set.seed(3); n<-400
dat <- gamSim(1,n=n)
dat$y <- dat$f + rt(n,df=4)*2

b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=scat(link="identity"),data=dat)

b
plot(b,pages=1)
```

---

sdiag

*Extract or modify diagonals of a matrix*

---

**Description**

Extracts or modifies sub- or super- diagonals of a matrix.

**Usage**

```
sdiag(A,k=0)
sdiag(A,k=0) <- value
```

**Arguments**

|       |                                                                                       |
|-------|---------------------------------------------------------------------------------------|
| A     | a matrix                                                                              |
| k     | sub- (negative) or super- (positive) diagonal of a matrix. 0 is the leading diagonal. |
| value | single value, or vector of the same length as the diagonal.                           |

**Value**

A vector containing the requested diagonal, or a matrix with the requested diagonal replaced by value.

**Author(s)**

## Examples

```
require(mgcv)
A <- matrix(1:35,7,5)
A
sdiag(A,1) ## first super diagonal
sdiag(A,-1) ## first sub diagonal

sdiag(A) <- 1 ## leading diagonal set to 1
sdiag(A,3) <- c(-1,-2) ## set 3rd super diagonal
```

shash

*Sinh-arcsinh location scale and shape model family*

## Description

The shash family implements the four-parameter sinh-arcsinh (shash) distribution of Jones and Pewsey (2009). The location, scale, skewness and kurtosis of the density can depend on additive smooth predictors. Useable only with gam, the linear predictors are specified via a list of formulae. It is worth carefully considering whether the data are sufficient to support estimation of such a flexible model before using it.

## Usage

```
shash(link = list("identity", "logeb", "identity", "identity"),
 b = 1e-2, phiPen = 1e-3)
```

## Arguments

|        |                                                                                                                                |
|--------|--------------------------------------------------------------------------------------------------------------------------------|
| link   | vector of four characters indicating the link function for location, scale, skewness and kurtosis parameters.                  |
| b      | positive parameter of the logeb link function, see Details.                                                                    |
| phiPen | positive multiplier of a ridge penalty on kurtosis parameter. Do not touch it unless you know what you are doing, see Details. |

## Details

The density function of the shash family is

$$p(y|\mu, \sigma, \epsilon, \delta) = C(z) \exp\{-S(z)^2/2\} \{2\pi(1+z^2)\}^{-1/2}/\sigma,$$

where  $C(z) = \{1 + S(z)^2\}^{1/2}$ ,  $S(z) = \sinh\{\delta \sinh^{-1}(z) - \epsilon\}$  and  $z = (y - \mu)/(\sigma\delta)$ . Here  $\mu$  and  $\sigma > 0$  control, respectively, location and scale,  $\epsilon$  determines skewness, while  $\delta > 0$  controls tailweight. shash can model skewness to either side, depending on the sign of  $\epsilon$ . Also, shash can have tails that are lighter ( $\delta > 1$ ) or heavier ( $0 < \delta < 1$ ) than a normal. For fitting purposes, here we are using  $\tau = \log(\sigma)$  and  $\phi = \log(\delta)$ .

The density is based on the expression given on the second line of section 4.1 and equation (2) of Jones and Pewsey (2009), and uses the simple reparameterization given in section 4.3.

The link function used for  $\tau$  is logeb with  $\eta = \log\{\exp(\tau) - b\}$  so that the inverse link is  $\tau = \log(\sigma) = \log\{\exp(\eta) + b\}$ . The point is that we don't allow  $\sigma$  to become smaller than a small constant b. The likelihood includes a ridge penalty  $-\text{phiPen} * \phi^2$ , which shrinks  $\phi$  toward

zero. When sufficient data is available the ridge penalty does not change the fit much, but it is useful to include it when fitting the model to small data sets, to avoid  $\phi$  diverging to  $+\infty$  (a problem already identified by Jones and Pewsey (2009)).

### Value

An object inheriting from class `general.family`.

#####
Motorcycle example
#####

Here shash is overkill, in fact the fit is not good, relative
to what we would get with mgcv::gaulss
library(MASS)

b <- gam(list(accel~s(times, k=20, bs = "ad"), ~s(times, k = 10), ~1, ~1),
 data=mcycle, family=shash)

par(mfrow = c(1, 1))
xSeq <- data.frame(cbind("accel" = rep(0, 1e3),
 "times" = seq(2, 58, length.out = 1e3)))
pred <- predict(b, newdata = xSeq)
plot(mcycle$times, mcycle$accel, ylim = c(-180, 100))
for(qq in c(0.1, 0.3, 0.5, 0.7, 0.9)){
 est <- b$family$qf(p=qq, mu = pred)
 lines(xSeq$times, est, type = 'l', col = 2)
}

plot(b, pages = 1, scale = FALSE)

```

## Description

Single index models contain smooth terms with arguments that are linear combinations of other covariates. e.g.  $s(X\alpha)$  where  $\alpha$  has to be estimated. For identifiability, assume  $\|\alpha\| = 1$  with positive first element. One simple way to fit such models is to use [gam](#) to profile out the smooth model coefficients and smoothing parameters, leaving only the  $\alpha$  to be estimated by a general purpose optimizer.

Example code is provided below, which can be easily adapted to include multiple single index terms, parametric terms and further smooths. Note the initialization strategy. First estimate  $\alpha$  without penalization to get starting values and then do the full fit. Otherwise it is easy to get trapped in a local optimum in which the smooth is linear. An alternative is to initialize using fixed penalization (via the `sp` argument to [gam](#)).

## Examples

```
require(mgcv)

si <- function(theta,y,x,z,opt=TRUE,k=10,fx=FALSE) {
 ## Fit single index model using gam call, given theta (defines alpha).
 ## Return ML if opt==TRUE and fitted gam with theta added otherwise.
 ## Suitable for calling from 'optim' to find optimal theta/alpha.
 alpha <- c(1,theta) ## constrained alpha defined using free theta
 kk <- sqrt(sum(alpha^2))
 alpha <- alpha/kk ## so now ||alpha||=1
 a <- x%*%alpha ## argument of smooth
 b <- gam(y~s(a,fx=fx,k=k)+s(z),family=poisson,method="ML") ## fit model
 if (opt) return(b$gcv.ubre) else {
 b$alpha <- alpha ## add alpha
 J <- outer(alpha,-theta/kk^2) ## compute Jacobian
 for (j in 1:length(theta)) J[j+1,j] <- J[j+1,j] + 1/kk
 b$J <- J ## dalpha_i/dtheta_j
 return(b)
 }
} ## si

simulate some data from a single index model...

set.seed(1)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
n <- 200;m <- 3
x <- matrix(runif(n*m),n,m) ## the covariates for the single index part
z <- runif(n) ## another covariate
alpha <- c(1,-1,.5); alpha <- alpha/sqrt(sum(alpha^2))
eta <- as.numeric(f2((x%*%alpha+.41)/1.4)+1+z^2*2)/4
mu <- exp(eta)
y <- rpois(n,mu) ## Poi response

now fit to the simulated data...

th0 <- c(-.8,.4) ## close to truth for speed
```

```

get initial theta, using no penalization...
f0 <- nlm(si,th0,y=y,x=x,z=z,fx=TRUE,k=5)
now get theta/alpha with smoothing parameter selection...
f1 <- nlm(si,f0$estimate,y=y,x=x,z=z,hessian=TRUE,k=10)
theta.est <-f1$estimate

Alternative using 'optim'...

th0 <- rep(0,m-1)
get initial theta, using no penalization...
f0 <- optim(th0,si,y=y,x=x,z=z,fx=TRUE,k=5)
now get theta/alpha with smoothing parameter selection...
f1 <- optim(f0$par,si,y=y,x=x,z=z,hessian=TRUE,k=10)
theta.est <-f1$par

extract and examine fitted model...

b <- si(theta.est,y,x,z,opt=FALSE) ## extract best fit model
plot(b,pages=1)
b
b$alpha
get sd for alpha...
Vt <- b$J%*%solve(f1$hessian,t(b$J))
diag(Vt)^.5

```

Sl.inirep

*Re-parametrizing model matrix X*

### Description

INTERNAL routine to apply initial Sl re-parameterization to model matrix X, or, if `inverse==TRUE`, to apply inverse re-parametrization to parameter vector or covariance matrix.

### Usage

```
Sl.inirep(Sl,X,l,r,nt=1)
```

```
Sl.initial.repara(Sl, X, inverse = FALSE, both.sides = TRUE, cov = TRUE,
 nt = 1)
```

### Arguments

|         |                                                                                                                      |
|---------|----------------------------------------------------------------------------------------------------------------------|
| Sl      | the output of Sl.setup.                                                                                              |
| X       | the model matrix.                                                                                                    |
| l       | if non-zero apply transform (positive) or inverse transform from left. 1 or -1 of transform, 2 or -2 for transpose.  |
| r       | if non-zero apply transform (positive) or inverse transform from right. 1 or -1 of transform, 2 or -2 for transpose. |
| inverse | if TRUE an inverse re-parametrization is performed.                                                                  |

|            |                                                                                                                                                                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| both.sides | if inverse==TRUE and both.sides==FALSE then the re-parametrization only applied to rhs, as appropriate for a choleski factor. If both.sides==FALSE, X is a vector and inverse==FALSE then X is taken as a coefficient vector (so re-parametrization is inverse of that for the model matrix). |
| cov        | boolean indicating whether X is a covariance matrix.                                                                                                                                                                                                                                          |
| nt         | number of parallel threads to be used.                                                                                                                                                                                                                                                        |

**Value**

A re-parametrized version of X.

**Author(s)**

**Description**

INTERNAL routine to apply re-parameterization from log-determinant of penalty matrix, ldetS to model matrix, X, blockwise.

**Usage**

Sl.repara(rp, X, inverse = FALSE, both.sides = TRUE)

**Arguments**

|            |                                                                                                                                                                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rp         | reparametrization.                                                                                                                                                                                                                                                                            |
| X          | if X is a matrix it is assumed to be a model matrix whereas if X is a vector it is assumed to be a parameter vector.                                                                                                                                                                          |
| inverse    | if TRUE an inverse re-parametrization is performed.                                                                                                                                                                                                                                           |
| both.sides | if inverse==TRUE and both.sides==FALSE then the re-parametrization only applied to rhs, as appropriate for a choleski factor. If both.sides==FALSE, X is a vector and inverse==FALSE then X is taken as a coefficient vector (so re-parametrization is inverse of that for the model matrix). |

**Value**

A re-parametrized version of X.

Sl.setup

*Setting up a list representing a block diagonal penalty matrix***Description**

INTERNAL function for setting up a list representing a block diagonal penalty matrix from the object produced by gam.setup.

**Usage**

```
Sl.setup(G,cholesky=FALSE,no.repara=FALSE,sparse=FALSE,keepS=FALSE)
```

**Arguments**

|           |                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------|
| G         | the output of gam.setup.                                                                                                   |
| cholesky  | re-parameterize using Cholesky only.                                                                                       |
| no.repara | set to TRUE to turn off all initial reparameterization.                                                                    |
| sparse    | sparse setup?                                                                                                              |
| keepS     | store original penalties in S0? (after any splitting of multiple penalties into singletons, but before reparameterization) |

**Value**

A list with an element for each block. For block, b, Sl[[b]] is a list with the following elements

- repara: should re-parameterization be applied to model matrix, etc? Usually FALSE if non-linear in coefficients.
- start, stop: such that start:stop are the indexes of the parameters of this block.
- S: a list of penalty matrices for the block (dim = stop-start+1) If length(S)==1 then this will be an identity penalty. Otherwise it is a multiple penalty, and an rS list of square root penalty matrices will be added. S (if repara==TRUE) and rS (always) will be projected into range space of total penalty matrix.
- rS: square root of penalty matrices if multiple penalties are used.
- D: a reparameterization matrix for the block. Applies to cols/params in start:stop. If numeric then  $X[,start:stop] \% \% \text{diag}(D)$  is re-parametrization of  $X[,start:stop]$ , and  $b.orig = D * b.repara$  (where b.orig is the original parameter vector). If matrix then  $X[,start:stop] \% \% D$  is re-parametrization of  $X[,start:stop]$ , and  $b.orig = D \% \% b.repara$  (where b.orig is the original parameter vector).
- S0: original penalties if requested.

slanczos

*Compute truncated eigen decomposition of a symmetric matrix***Description**

Uses Lanczos iteration to find the truncated eigen-decomposition of a symmetric matrix.

**Usage**

```
slanczos(A,k=10,k1=-1,tol=.Machine$double.eps^.5,nt=1)
```

**Arguments**

|     |                                                                                                                                                                                                                                                                                                               |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A   | A symmetric matrix.                                                                                                                                                                                                                                                                                           |
| k   | Must be non-negative. If k1 is negative, then the k largest magnitude eigenvalues are found, together with the corresponding eigenvectors. If k1 is non-negative then the k highest eigenvalues are found together with their eigenvectors and the k1 lowest eigenvalues with eigenvectors are also returned. |
| k1  | If k1 is non-negative then the k1 lowest eigenvalues are returned together with their corresponding eigenvectors (in addition to the k highest eigenvalues + vectors). negative k1 signals that the k largest magnitude eigenvalues should be returned, with eigenvectors.                                    |
| tol | tolerance to use for convergence testing of eigenvalues. Error in eigenvalues will be less than the magnitude of the dominant eigenvalue multiplied by tol (or the machine precision!).                                                                                                                       |
| nt  | number of threads to use for leading order iterative multiplication of A by vector. May show no speed improvement on two processor machine.                                                                                                                                                                   |

**Details**

If k1 is non-negative, returns the highest k and lowest k1 eigenvalues, with their corresponding eigenvectors. If k1 is negative, returns the largest magnitude k eigenvalues, with corresponding eigenvectors.

The routine implements Lanczos iteration with full re-orthogonalization as described in Demmel (1997). Lanczos iteration iteratively constructs a tridiagonal matrix, the eigenvalues of which converge to the eigenvalues of A, as the iteration proceeds (most extreme first). Eigenvectors can also be computed. For small k and k1 the approach is faster than computing the full symmetric eigendecomposition. The tridiagonal eigenproblems are handled using LAPACK.

The implementation is not optimal: in particular the inner tridiagonal problems could be handled more efficiently, and there would be some savings to be made by not always returning eigenvectors.

**Value**

A list with elements values (array of eigenvalues); vectors (matrix with eigenvectors in its columns); iter (number of iterations required).

## Examples

```
require(mgcv)
create some x's and knots...
set.seed(1);
n <- 700; A <- matrix(runif(n*n),n,n); A <- A+t(A)

compare timings of slanczos and eigen
system.time(er <- slanczos(A,10))
system.time(um <- eigen(A,symmetric=TRUE))

confirm values are the same...
ind <- c(1:6,(n-3):n)
range(er$values-um$values[ind]); range(abs(er$vectors)-abs(um$vectors[,ind]))
```

---

smooth.construct

*Constructor functions for smooth terms in a GAM*

---

## Description

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. New smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function (see example code below).

In practice, `smooth.construct` is usually called via `smooth.construct2` and the wrapper function [smoothCon](#), in order to handle by variables and centering constraints (see the [smoothCon](#) documentation if you need to handle these things directly, for a user defined smooth class).

## Usage

```
smooth.construct(object,data,knots)
smooth.construct2(object,data,knots)
```

## Arguments

**object** is a smooth specification object, generated by an [s](#) or [te](#) term in a GAM formula. Objects generated by `s` terms have class `xx.smooth.spec` where `xx` is given by the `bs` argument of `s` (this convention allows the user to add their own smoothers). If object is not class `tensor.smooth.spec` it will have the following elements:

**term** The names of the covariates for this smooth, in an array.

**bs.dim** Argument *k* of the *s* term generating the object. This is the dimension of the basis used to represent the term (or, arguably, 1 greater than the basis dimension for *cc* terms). *bs.dim*<0 indicates that the constructor should set this to the default value.

**fixed** TRUE if the term is to be unpenalized, otherwise FALSE.

**dim** the number covariates of which this smooth is a function.

**p.order** the order of the smoothness penalty or NA for autoselection of this. This is argument *m* of the *s* term that generated object.

**by** the name of any by variable to multiply this term as supplied as an argument to *s*. "NA" if there is no such term.

**label** A suitable label for use with this term.

**xt** An object containing information that may be needed for basis setup (used, e.g. by "tp" smooths to pass optional information on big dataset handling).

**id** Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

**sp** Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides *sp* argument to [gam](#).

If object is of class `tensor.smooth.spec` then it was generated by a *te* term in the GAM formula, and specifies a smooth of several variables with a basis generated as a tensor product of lower dimensional bases. In this case the object will be different and will have the following elements:

**margin** is a list of smooth specification objects of the type listed above, defining the bases which have their tensor product formed in order to construct this term.

**term** is the array of names of the covariates that are arguments of the smooth.

**by** is the name of any by variable, or "NA".

**fx** is an array, the elements of which indicate whether (TRUE) any of the margins in the tensor product should be unpenalized.

**label** A suitable label for use with this term.

**dim** is the number of covariates of which this smooth is a function.

**mp** TRUE if multiple penalties are to be used.

**np** TRUE if 1-D marginal smooths are to be re-parameterized in terms of function values.

**id** Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

**sp** Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides *sp* argument to [gam](#).

**data** For `smooth.construct` a data frame or list containing the evaluation of the elements of `object$term`, with names given by `object$term`. The last entry will be the by variable, if `object$by` is not "NA". For `smooth.construct2` data need only be an object within which `object$term` can be evaluated, the variables can be in any order, and there can be irrelevant variables present as well.

**knots** an optional data frame or list containing the knots relating to `object$term`. If it is NULL then the knot locations are generated automatically. The structure of knots should be as for `data`, depending on whether `smooth.construct` or `smooth.construct2` is used.

## Details

There are built in methods for objects with the following classes: `tp.smooth.spec` (thin plate regression splines: see [tprs](#)); `ts.smooth.spec` (thin plate regression splines with shrinkage-to-zero); `cr.smooth.spec` (cubic regression splines: see [cubic.regression.spline](#)); `cs.smooth.spec` (cubic regression splines with shrinkage-to-zero); `cc.smooth.spec` (cyclic cubic regression splines); `ps.smooth.spec` (Eilers and Marx (1986) style P-splines: see [p.spline](#)); `cp.smooth.spec` (cyclic P-splines); `ad.smooth.spec` (adaptive smooths of 1 or 2 variables: see [adaptive.smooth](#)); `re.smooth.spec` (simple random effect terms); `mrf.smooth.spec` (Markov random field smoothers for smoothing over discrete districts); `tensor.smooth.spec` (tensor product smooths).

There is an implicit assumption that the basis only depends on the knots and/or the set of unique covariate combinations; i.e. that the basis is the same whether generated from the full set of covariates, or just the unique combinations of covariates.

Plotting of smooths is handled by plot methods for smooth objects. A default `mgcv.smooth` method is used if there is no more specific method available. Plot methods can be added for specific smooth classes, see source code for `mgcv::plot.sos.smooth`, `mgcv::plot.random.effect`, `mgcv::plot.mgcv.smooth` for example code.

## Value

The input argument object, assigned a new class to indicate what type of smooth it is and with at least the following items added:

|                             |                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>X</code>              | The model matrix from this term. This may have an "offset" attribute: a vector of length <code>nrow(X)</code> containing any contribution of the smooth to the model offset term. <code>by.variables</code> do not need to be dealt with here, but if they are then an item <code>by.done</code> must be added to the object. |
| <code>S</code>              | A list of positive semi-definite penalty matrices that apply to this term. The list will be empty if the term is to be left un-penalized.                                                                                                                                                                                     |
| <code>rank</code>           | An array giving the ranks of the penalties.                                                                                                                                                                                                                                                                                   |
| <code>null.space.dim</code> | The dimension of the penalty null space (before centering).                                                                                                                                                                                                                                                                   |

The following items may be added:

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>C</code>          | The matrix defining any identifiability constraints on the term, for use when fitting. If this is <code>NULL</code> then <code>smoothCon</code> will add an identifiability constraint that each term should sum to zero over the covariate values. Set to a zero row matrix if no constraints are required. If a supplied <code>C</code> has an attribute "always.apply" then it is never ignored, even if any <code>by.variables</code> of a smooth imply that no constraint is actually needed. Code for creating <code>C</code> should check whether the specification object already contains a zero row matrix, and leave this unchanged if it is (since this signifies no constraint should be produced). |
| <code>Cp</code>         | An optional matrix supplying alternative identifiability constraints for use when predicting. By default the fitting constraints are used. This option is useful when some sort of simple sparse constraint is required for fitting, but the usual sum-to-zero constraint is required for prediction so that, e.g. the CIs for model components are as narrow as possible.                                                                                                                                                                                                                                                                                                                                       |
| <code>no.rescale</code> | if this is non- <code>NULL</code> then the penalty coefficient matrix of the smooth will not be rescaled for enhanced numerical stability (rescaling is the default, because <a href="#">gamm</a> requires it). Turning off rescaling is useful if the values of the smoothing parameters should be interpretable in a model, for example because they are inverse variance components.                                                                                                                                                                                                                                                                                                                          |

|                |                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| df             | the degrees of freedom associated with this term (when unpenalized and unconstrained). If this is null then smoothCon will set it to the basis dimension. smoothCon will reduce this by the number of constraints.                                                                                                                                                                |
| te.ok          | 0 if this term should not be used as a tensor product marginal, 1 if it can be used and plotted, and 2 if it can be used but not plotted. Set to 1 if NULL.                                                                                                                                                                                                                       |
| plot.me        | Set to FALSE if this smooth should not be plotted by <code>plot.gam</code> . Set to TRUE if NULL.                                                                                                                                                                                                                                                                                 |
| side.constrain | Set to FALSE to ensure that the smooth is never subject to side constraints as a result of nesting.                                                                                                                                                                                                                                                                               |
| L              | smooths may depend on fewer ‘underlying’ smoothing parameters than there are elements of S. In this case L is the matrix mapping the vector of underlying log smoothing parameters to the vector of logs of the smoothing parameters actually multiplying the <code>S[[i]]</code> . <code>L=NULL</code> signifies that there is one smoothing parameter per <code>S[[i]]</code> . |

Usually the returned object will also include extra information required to define the basis, and used by `Predict.matrix` methods to make predictions using the basis. See the Details section for links to the information included for the built in smooth classes.

`tensor.smooth` returned objects will additionally have each element of the `margin` list updated in the same way. `tensor.smooths` also have a list, `XP`, containing re-parameterization matrices for any 1-D marginal terms re-parameterized in terms of function values. This list will have NULL entries for marginal smooths that are not re-parameterized, and is only long enough to reach the last re-parameterized marginal in the list.

## WARNING

User defined smooth objects should avoid having attributes names "qrc" or "nCons" as these are used internally to provide constraint free parameterizations.

smooth.construct.ad.smooth.spec

*Adaptive smooths in GAMs*

---

## Description

`gam` can use adaptive smooths of one or two variables, specified via terms like `s(...,bs="ad",...)`. (`gamm` can not use such terms — check out package `AdaptFit` if this is a problem.) The basis for such a term is a (tensor product of) p-spline(s) or cubic regression spline(s). Discrete P-spline type penalties are applied directly to the coefficients of the basis, but the penalties themselves have a basis representation, allowing the strength of the penalty to vary with the covariates. The coefficients of the penalty basis are the smoothing parameters.

When invoking an adaptive smoother the `k` argument specifies the dimension of the smoothing basis (default 40 in 1D, 15 in 2D), while the `m` argument specifies the dimension of the penalty basis (default 5 in 1D, 3 in 2D). For an adaptive smooth of two variables `k` is taken as the dimension of both marginal bases: different marginal basis dimensions can be specified by making `k` a two element vector. Similarly, in the two dimensional case `m` is the dimension of both marginal bases for the penalties, unless it is a two element vector, which specifies different basis dimensions for each marginal (If the penalty basis is based on a thin plate spline then `m` specifies its dimension directly).

By default, P-splines are used for the smoothing and penalty bases, but this can be modified by supplying a list as argument `xt` with a character vector `xt$bs` specifying the smoothing basis type. Only "ps", "cp", "cc" and "cr" may be used for the smoothing basis. The penalty basis is always a B-spline, or a cyclic B-spline for cyclic bases.

The total number of smoothing parameters to be estimated for the term will be the dimension of the penalty basis. Bear in mind that adaptive smoothing places quite severe demands on the data. For example, setting `m=10` for a univariate smooth of 200 data is rather like estimating 10 smoothing parameters, each from a data series of length 20. The problem is particularly serious for smooths of 2 variables, where the number of smoothing parameters required to get reasonable flexibility in the penalty can grow rather fast, but it often requires a very large smoothing basis dimension to make good use of this flexibility. In short, adaptive smooths should be used sparingly and with care.

Shape constrained versions are available for use with `scasm`, with constraints specified as in `smooth.construct.sc.smooth.spec`.

In practice it is often as effective to simply transform the smoothing covariate as it is to use an adaptive smooth.

**Usage**

```
S3 method for class 'ad.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'scad.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

|        |                                                                                                                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | a smooth specification object, usually generated by a term <code>s(...,bs="ad",...)</code>                                                                                                                    |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| knots  | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL                                                                                                 |

**Details**

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use [smooth.construct2](#).

This class can not be used as a marginal basis in a tensor product smooth, nor by `gamm`.

**Value**

An object of class `"pspline.smooth"` in the 1D case or `"tensor.smooth"` in the 2D case.

smooth.construct.bs.smooth.spec

*Penalized B-splines in GAMs*

---

## Description

`gam` can use smoothing splines based on univariate B-spline bases with derivative based penalties, specified via terms like `s(x,bs="bs",m=c(3,2))`. `m[1]` controls the spline order, with `m[1]=3` being a cubic spline, `m[1]=2` being quadratic, and so on. The integrated square of the `m[2]`th derivative is used as the penalty. So `m=c(3,2)` is a conventional cubic spline. Any further elements of `m`, after the first 2, define the order of derivative in further penalties. If `m` is supplied as a single number, then it is taken to be `m[1]` and `m[2]=m[1]-1`, which is only a conventional smoothing spline in the `m=3`, cubic spline case. Notice that the definition of the spline order in terms of `m[1]` is intuitive, but differs to that used with the `tprs` and `p.spline` bases. See details for options for

controlling the interval over which the penalty is evaluated (which can matter if it is necessary to extrapolate).

Shape constrained "sc" versions are available for use with [scasm](#).

## Usage

```
S3 method for class 'bs.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'sc.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'Bspline.smooth'
Predict.matrix(object, data)
```

## Arguments

|        |                                                                                                                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | a smooth specification object, usually generated by a term <code>s(x, bs="bs", ...)</code>                                                                                                                    |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| knots  | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details for further information.                                                           |

## Details

The basis and penalty are sparse (although sparse matrices are not used to represent them). `m[2]>m[1]` will generate an error, since in that case the penalty would be based on an undefined derivative of the basis, which makes no sense. The terms can have multiple penalties of different orders, for example `s(x, bs="bs", m=c(3, 2, 1, 0))` specifies a cubic basis with 3 penalties: a conventional cubic spline penalty, an integrated square of first derivative penalty, and an integrated square of function value penalty.

The default basis dimension, `k`, is the larger of 10 and `m[1]`. `m[1]` is the lower limit on basis dimension. If knots are supplied, then the number of supplied knots should be `k + m[1] + 1`, and the range of the middle `k-m[1]+1` knots should include all the covariate values. Alternatively, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (making this range too wide mean that there is no information about some basis coefficients, because the corresponding basis functions have a span that includes no data). Unlike P-splines, splines with derivative based penalties can have uneven knot spacing, without a problem.

Another option is to supply 4 knots. Then the outer 2 define the interval over which the penalty is to be evaluated, while the inner 2 define an interval within which all but the outermost 2 knots should lie. Normally the outer 2 knots would be the interval over which predictions might be required, while the inner 2 knots define the interval within which the data lie. This option allows the penalty to apply over a wider interval than the data, while still placing most of the basis functions where the data are. This is useful in situations in which it is necessary to extrapolate slightly with a smooth. Only applying the penalty over the interval containing the data amounts to a model in which the function could be less smooth outside the interval than within it, and leads to very wide extrapolation confidence intervals. However the alternative of evaluating the penalty over the whole real line amounts to asserting certainty that the function has some derivative zeroed away from the data, which is equally unreasonable. It is preferable to build a model in which the same smoothness assumptions apply over both data and extrapolation intervals, but not over the whole real line. See example code for practical illustration.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior  $k-m[1]+1$  knots — the interval over which the penalty is evaluated). Such extrapolation is not allowed in basis construction, but is when predicting.

It is possible to set a `deriv` flag in a smooth specification or smooth object, so that a model or prediction matrix produces the requested derivative of the spline, rather than evaluating it.

Shape constrained versions for use with `scasm` are specified by model terms like `s(x,bs="sc",xt="m+")` for a monotonic increasing function, or `s(x,bs="sc",xt=c("m+","c-"))` for increasing and concave (negative second derivative). The vector supplied for `xt` can contain any meaningful combination of "+" (positive), "m+" (increasing), "m-" (decreasing), "c+" (convex) and "c-" (concave). The constraints will only be processed when used with `scasm`. Constraints can be used in tensor product terms.

### Value

An object of class "Bspline.smooth". See `smooth.construct`, for the elements that this object will contain.

### WARNING

`m[1]` directly controls the spline order here, which is intuitively sensible, but different to other bases.

 method="ML")
options(op)
and the equivalent with same penalty over data range only (blue)
b1 <- gam(y~s(x,bs="bs",m=c(3,1),k=20),method="ML")
pd <- data.frame(x=seq(-.7,1.7,length=200))
fv <- predict(b,pd,se=TRUE)
ul <- fv$fit + fv$se.fit*2; ll <- fv$fit - fv$se.fit*2
plot(x,y,xlim=c(-.7,1.7),ylim=range(c(y,ll,ul)),main=
 "Order 1 penalties: red tps; blue bs on (0,1); black bs on (-.5,1.5)")
penalty defined on (-.5,1.5) gives plausible predictions and intervals
over this range...
lines(pdx,fvfit);lines(pd$x,ul,lty=2);lines(pd$x,ll,lty=2)
fv <- predict(b0,pd,se=TRUE)
ul <- fv$fit + fv$se.fit*2; ll <- fv$fit - fv$se.fit*2
penalty defined on whole real line gives constant width intervals away
from data, as slope there must be zero, to avoid infinite penalty:
lines(pdx,fvfit,col=2)
lines(pd$x,ul,lty=2,col=2);lines(pd$x,ll,lty=2,col=2)
fv <- predict(b1,pd,se=TRUE)
ul <- fv$fit + fv$se.fit*2; ll <- fv$fit - fv$se.fit*2
penalty defined only over the data interval (0,1) gives wild and wide
extrapolation since penalty has been 'turned off' outside data range:
lines(pdx,fvfit,col=4)
lines(pd$x,ul,lty=2,col=4);lines(pd$x,ll,lty=2,col=4)

construct smooth of x. Model matrix sm$X and penalty
matrix sm$S[[1]] will have many zero entries...
x <- seq(0,1,length=100)
sm <- smoothCon(s(x,bs="bs"),data.frame(x))[[1]]

another example checking penalty numerically...

smooth.construct.cr.smooth.spec

*Penalized Cubic regression splines in GAMs*

---

## Description

[gam](#) can use univariate penalized cubic regression spline smooths, specified via terms like `s(x,bs="cr")`. `s(x,bs="cs")` specifies a penalized cubic regression spline which has had its penalty modified to shrink towards zero at high enough smoothing parameters (as the smoothing parameter goes to infinity a normal cubic spline tends to a straight line.) `s(x,bs="cc")` specifies a cyclic penalized cubic regression spline smooth.

‘Cardinal’ spline bases are used: Wood (2017) sections 5.3.1 and 5.3.2 gives full details. These bases have very low setup costs. For a given basis dimension,  $k$ , they typically perform a little less well than thin plate regression splines, but a little better than p-splines. See [te](#) to use these bases in tensor product smooths of several variables.

Default  $k$  is 10.

## Usage

```
S3 method for class 'cr.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'cs.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'cc.smooth.spec'
smooth.construct(object, data, knots)
```

## Arguments

|                     |                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a smooth specification object, usually generated by a term <code>s(...,bs="cr",...)</code> , <code>s(...,bs="cs",...)</code> or <code>s(...,bs="cc",...)</code>                                               |
| <code>data</code>   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| <code>knots</code>  | a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be NULL. See details.                                                                     |

## Details

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use [smooth.construct2](#).

If they are not supplied then the knots of the spline are placed evenly throughout the covariate values to which the term refers: For example, if fitting 101 data with an 11 knot spline of  $x$  then there would be a knot at every 10th (ordered)  $x$  value. The parameterization used represents the spline in terms of its values at the knots. The values at neighbouring knots are connected by sections of cubic polynomial constrained to be continuous up to and including second derivative at the knots. The resulting curve is a natural cubic spline through the values at the knots (given two extra conditions specifying that the second derivative of the curve should be zero at the two end knots).

The shrinkage version of the smooth, eigen-decomposes the wiggleness penalty matrix, and sets its 2 zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then

set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

Note that the cyclic smoother will wrap at the smallest and largest covariate values, unless knots are supplied. If only two knots are supplied then they are taken as the end points of the smoother (provided all the data lie between them), and the remaining knots are generated automatically.

The cyclic smooth is not subject to the condition that second derivatives go to zero at the first and last knots.

## Value

An object of class "cr.smooth" "cs.smooth" or "cyclic.smooth". In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|    |                                                                                                                                   |
|----|-----------------------------------------------------------------------------------------------------------------------------------|
| xp | giving the knot locations used to generate the basis.                                                                             |
| F  | For class "cr.smooth" and "cs.smooth" objects $t(F)$ transforms function values at the knots to second derivatives at the knots.  |
| BD | class "cyclic.smooth" objects include matrix BD which transforms function values at the knots to second derivatives at the knots. |

smooth.construct.ds.smooth.spec

*Low rank Duchon 1977 splines*

---

## Description

Thin plate spline smoothers are a special case of the isotropic splines discussed in Duchon (1977). A subset of this more general class can be invoked by terms like `s(x, z, bs="ds", m=c(1, .5))` in a [gam](#) model formula. In the notation of Duchon (1977) `m` is given by `m[1]` (default value 2), while `s` is given by `m[2]` (default value 0).

Duchon's (1977) construction generalizes the usual thin plate spline penalty as follows. The usual TPS penalty is given by the integral of the squared Euclidian norm of a vector of mixed partial `m`th order derivatives of the function w.r.t. its arguments. Duchon re-expresses this penalty in the Fourier domain, and then weights the squared norm in the integral by the Euclidean norm of the fourier frequencies, raised to the power `2s`. `s` is a user selected constant taking integer values divided by 2. If `d` is the number of arguments of the smooth, then it is required that  $-d/2 < s < d/2$ . To obtain continuous functions we further require that  $m + s > d/2$ . If `s=0` then the usual thin plate spline is recovered.

The construction is amenable to exactly the low rank approximation method given in Wood (2003) to thin plate splines, with similar optimality properties, so this approach to low rank smoothing is used here. For large datasets the same subsampling approach as is used in the [tprs](#) case is employed here to reduce computational costs.

These smoothers allow the use of lower orders of derivative in the penalty than conventional thin plate splines, while still yielding continuous functions. For example, we can set `m = 1` and `s = d/2 - .5` in order to use first derivative penalization for any `d` (which has the advantage that the dimension of the null space of unpenalized functions is only `d+1`).

| <code>knots</code>  | a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code> .                                                                    |

## Details

The default basis dimension for this class is `k=M+k.def` where `M` is the null space dimension (dimension of unpenalized function space) and `k.def` is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized

regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use [smooth.construct2](#).

For these classes the specification object will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 'knots' from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to [s](#). This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not effect the state of R's RNG.

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the `tp` basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, `k`. This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, `k`. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

## Value

An object of class "duchon.spline". In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|                                   |                                                                                                                                                                                               |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>shift</code>                | A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otehrwise occur in the penalty null space basis of the term. |
| <code>Xu</code>                   | A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).                                                          |
| <code>UZ</code>                   | The matrix mapping the smoother parameters back to the parameters of a full Duchon spline.                                                                                                    |
| <code>null.space.dimension</code> | The dimension of the space of functions that have zero wiggleness according to the wiggleness penalty for this term.                                                                          |

smooth.construct.fs.smooth.spec

*Factor smooth interactions in GAMs*

---

**Description**

Simple factor smooth interactions, which are efficient when used with [gamm](#). This smooth class allows a separate smooth for each level of a factor, with the same smoothing parameter for all smooths. It is an alternative to using factor by variables.

See [factor.smooth](#) for more genral alternatives for factor smooth interactions (including interactions of tensor product smooths with factors).

**Usage**

```

S3 method for class 'fs.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'fs.interaction'
Predict.matrix(object, data)

```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | For the smooth.construct method a smooth specification object, usually generated by a term <code>s(x, ..., bs="fs", )</code> . May have a <code>gamm</code> attribute: see details. For the predict.Matrix method an object of class <code>"fs.interaction"</code> produced by the smooth.construct method. |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> .                                                                                                                                                                  |
| knots  | a list containing any knots supplied for smooth basis setup.                                                                                                                                                                                                                                                |

## Details

This class produces a smooth for each level of a single factor variable. Within a [gam](#) formula this is done with something like `s(x, fac, bs="fs")`, which is almost equivalent to `s(x, by=fac, id=1)` (with the `gam` argument `select=TRUE`). The terms are fully penalized, with separate penalties on each null space component: for this reason they are not centred (no sum-to-zero constraint).

The class is particularly useful for use with [gamm](#), where estimation efficiently exploits the nesting of the smooth within the factor. Note however that: i) `gamm` only allows one conditioning factor for smooths, so `s(x)+s(z, fac, bs="fs")+s(v, fac, bs="fs")` is OK, but `s(x)+s(z, fac1, bs="fs")+s(v, fac2, bs="fs")` is not; ii) all additional random effects and correlation structures will be treated as nested within the factor of the smooth factor interaction. To facilitate this the constructor is called from [gamm](#) with an attribute `"gamm"` attached to the smooth specification object. The result differs from that resulting from the case where this is not done.

Note that `gamm4` from the `gamm4` package suffers from none of the restrictions that apply to `gamm`, and `"fs"` terms can be used without side-effects. Constructor is still called with a smooth specification object having a `"gamm"` attribute.

Any singly penalized basis can be used to smooth at each factor level. The default is `"tp"`, but alternatives can be supplied in the `xt` argument of `s` (e.g. `s(x, fac, bs="fs", xt="cr")` or `s(x, fac, bs="fs", xt=list(bs="cr"))`). The `k` argument to `s(..., bs="fs")` refers to the basis dimension to use for each level of the factor variable.

Note one computational bottleneck: currently [gamm](#) (or `gamm4`) will produce the full posterior covariance matrix for the smooths, including the smooths at each level of the factor. This matrix can get large and computationally costly if there are more than a few hundred levels of the factor. Even at one or two hundred levels, care should be taken to keep down `k`.

The plot method for this class has two schemes. `scheme==0` is in colour, while `scheme==1` is black and white.

## Value

An object of class `"fs.interaction"` or a matrix mapping the coefficients of the factor smooth interaction to the smooths themselves. The contents of an `"fs.interaction"` object will depend on whether or not `smooth.construct` was called with an object with attribute `gamm`: see below.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)> with input from Matteo Fasiolo.

## See Also

[factor.smooth](#), [gamm](#), [smooth.construct.sz.smooth.spec](#)

## Examples

```
library(mgcv)
set.seed(0)
simulate data...
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x, a=2, b=-1) exp(a * x)+b
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
n <- 500; nf <- 25
fac <- sample(1:nf, n, replace=TRUE)
x0 <- runif(n); x1 <- runif(n); x2 <- runif(n)
```

```

a <- rnorm(nf)*.2 + 2;b <- rnorm(nf)*.5
f <- f0(x0) + f1(x1,a[fac],b[fac]) + f2(x2)
fac <- factor(fac)
y <- f + rnorm(n)*2
so response depends on global smooths of x0 and
x2, and a smooth of x1 for each level of fac.

fit model...
bm <- gamm(y~s(x0)+ s(x1,fac,bs="fs",k=5)+s(x2,k=20))
plot(bm$gam,pages=1)
summary(bm$gam)

Also efficient using bam(..., discrete=TRUE)
bd <- bam(y~s(x0)+ s(x1,fac,bs="fs",k=5)+s(x2,k=20),discrete=TRUE)
plot(bd,pages=1)
summary(bd)

Could also use...
b <- gamm(y~s(x0)+ s(x1,fac,bs="fs",k=5)+s(x2,k=20),method="ML")
... but its slower (increasingly so with increasing nf)
b <- gamm(y~s(x0)+ t2(x1,fac,bs=c("tp","re"),k=5,full=TRUE)+
s(x2,k=20),method="ML")
... is exactly equivalent.

```

---

smooth.construct.gp.smooth.spec

*Low rank Gaussian process smooths*

---

## Description

Gaussian process/kriging models based on simple covariance functions can be written in a very similar form to thin plate and Duchon spline models (e.g. Handcock, Meier, Nychka, 1994), and low rank versions produced by the eigen approximation method of Wood (2003). Kammann and Wand (2003) suggest a particularly simple form of the Matern covariance function with only a single smoothing parameter to estimate, and this class implements this and other similar models.

Usually invoked by an `s(...,bs="gp")` term in a `gam` formula. Argument `m` selects the covariance function, sets the range parameter and any power parameter. If `m` is not supplied then it defaults to NA and the covariance function suggested by Kammann and Wand (2003) along with their suggested range parameter is used. Otherwise `abs(m[1])` between 1 and 5 selects the correlation function from respectively, spherical, power exponential, and Matern with  $\kappa = 1.5, 2.5$  or  $3.5$ . The sign of `m[1]` determines whether a linear trend in the covariates is added to the Gaussian process (positive), or not (negative). The latter ensures stationarity. `m[2]`, if present, specifies the range parameter, with non-positive or absent indicating that the Kammann and Wand estimate should be used. `m[3]` can be used to specify the power for the power exponential which otherwise defaults to 1.

## Usage

```

S3 method for class 'gp.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'gp.smooth'
Predict.matrix(object, data)

```

## Arguments

|        |                                                                                                                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | a smooth specification object, usually generated by a term <code>s(...,bs="ms",...)</code> .                                                                                                                  |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| knots  | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL                                                                                                 |

## Details

Let  $\rho > 0$  be the range parameter,  $0 < \kappa \leq 2$  and  $d$  denote the distance between two points. Then the correlation functions indexed by `m[1]` are:

1.  $1 - 1.5d/\rho + 0.5(d/\rho)^3$  if  $d \leq \rho$  and 0 otherwise.
2.  $\exp(-(d/\rho)^\kappa)$ .
3.  $\exp(-d/\rho)(1 + d/\rho)$ .
4.  $\exp(-d/\rho)(1 + d/\rho + (d/\rho)^2/3)$ .
5.  $\exp(-d/\rho)(1 + d/\rho + 2(d/\rho)^2/5 + (d/\rho)^3/15)$ .

See Fahrmeir et al. (2013) section 8.1.6, for example. Note that setting  $r$  to too small a value will lead to unpleasant results, as most points become all but independent (especially for the spherical model. Note: Wood 2017, Figure 5.20 right is based on a buggy implementation).

The default basis dimension for this class is `k=M+k.def` where `M` is the null space dimension (dimension of unpenalized function space) and `k.def` is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

For these classes the specification object will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 'knots' from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to `s`. This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not effect the state of R's RNG.

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the `tp` basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, `k`. This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, `k`. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

**Value**

An object of class "gp.smooth". In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|                      |                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| shift                | A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term. |
| Xu                   | A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).                                                          |
| UZ                   | The matrix mapping the smoother parameters back to the parameters of a full GP smooth.                                                                                                        |
| null.space.dimension | The dimension of the space of functions that have zero wiggleness according to the wiggleness penalty for this term.                                                                          |
| gp.defn              | the type, range parameter and power parameter defining the correlation function.                                                                                                              |

smooth.construct.mrf.smooth.spec

*Markov Random Field Smoother*

---

## Description

For data observed over discrete spatial units, a simple Markov random field smoother is sometimes appropriate. These functions provide such a smoother class for mgcv. See details for how to deal with regions with missing data.

## Usage

```

S3 method for class 'mrf.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'mrf.smooth'
Predict.matrix(object, data)

```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | For the smooth.construct method a smooth specification object, usually generated by a term <code>s(x, ..., bs="mrf", xt=list(polys=foo))</code> . <code>x</code> is a factor variable giving labels for geographic districts, and the <code>xt</code> argument is obligatory: see details. For the Predict.matrix method an object of class "mrf.smooth" produced by the smooth.construct method. |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element.                                                                                                                                                                                     |
| knots  | If there are more geographic areas than data were observed for, then this argument is used to provide the labels for all the areas (observed and unobserved).                                                                                                                                                                                                                                     |

## Details

A Markov random field smooth over a set of discrete areas is defined using a set of area labels, and a neighbourhood structure for the areas. The covariate of the smooth is the vector of area labels corresponding to each observation. This covariate should be a factor, or capable of being coerced to a factor.

The neighbourhood structure is supplied in the `xt` argument to `s`. This must contain at least one of the elements `polys`, `nb` or `penalty`.

**polys** contains the polygons defining the geographic areas. It is a list with as many elements as there are geographic areas. `names(polys)` must correspond to the levels of the argument of the smooth, in any order (i.e. it gives the area labels). `polys[[i]]` is a 2 column matrix the

rows of which specify the vertices of the polygon(s) defining the boundary of the *i*th area. A boundary may be made up of several closed loops: these must be separated by NA rows. A polygon within another is treated as a hole. The first polygon in any `polys[[i]]` should not be a hole. An example of the structure is provided by `columb.polys` (which contains an artificial hole in its second element, for illustration). Any list elements with duplicate names are combined into a single NA separated matrix.

Plotting of the smooth is not possible without a `polys` object.

If `polys` is the only element of `xt` provided, then the neighbourhood structure is computed from it automatically. To count as neighbours, polygons must exactly share one or more vertices.

**nb** is a named list defining the neighbourhood structure. `names(nb)` must correspond to the levels of the covariate of the smooth (i.e. the area labels), but can be in any order. `nb[[i]]` is a numeric vector indexing the neighbours of the *i*th area (and should not include *i*). All indices are relative to `nb` itself, but can be translated using `names(nb)`. See example code. As an alternative each `nb[[i]]` can be an array of the names of the neighbours, but these will be converted to the arrays of numeric indices internally.

If no `penalty` is provided then it is computed automatically from this list. The *i*th row of the penalty matrix will be zero everywhere, except in the *i*th column, which will contain the number of neighbours of the *i*th geographic area, and the columns corresponding to those geographic neighbours, which will each contain -1.

**penalty** if this is supplied, then it is used as the penalty matrix. It should be positive semi-definite. Its row and column names should correspond to the levels of the covariate.

If no basis dimension is supplied then the constructor produces a full rank MRF, with a coefficient for each geographic area. Otherwise a low rank approximation is obtained based on truncation of the parameterization given in Wood (2017) Section 5.4.2. See Wood (2017, section 5.8.1).

Note that smooths of this class have a built in plot method, and that the utility function `in.out` can be useful for working with discrete area data. The plot method has two schemes, `scheme==0` is colour, `scheme==1` is grey scale.

The situation in which there are areas with no data requires special handling. You should set `drop.unused.levels=FALSE` in the model fitting function, `gam`, `bam` or `gamm`, having first ensured that any fixed effect factors do not contain unobserved levels. Also make sure that the basis dimension is set to ensure that the total number of coefficients is less than the number of observations.

## Value

An object of class `"mrf.smooth"` or a matrix mapping the coefficients of the MRF smooth to the predictions for the areas listed in data.

## Author(s)

Simon N. Wood <simon.wood@r-project.org> and Thomas Kneib (Fabian Scheipl prototyped the low rank MRF idea)

## References

head(nb)
names(nb) ## these have to match the factor levels of the smooth
look at the indices of the neighbours of the first entry,
named '0'...
nb[['0']] ## by name
nb[[1]] ## same by index
... and get the names of these neighbours from their indices...
names(nb)[nb[['0']]]
b1 <- gam(crime ~ s(district,bs="mrf",k=20,xt=list(nb=nb))+s(income),
 data=columb,method="REML")
b1 ## fit unchanged
plot(b1) ## but now there is no information with which to plot the mrf
```

---

smooth.construct.ps.smooth.spec

*P-splines in GAMs*

---

## Description

[gam](#) can use univariate P-splines as proposed by Eilers and Marx (1996), specified via terms like `s(x,bs="ps")`. These terms use B-spline bases penalized by discrete penalties applied directly to the basis coefficients. Cyclic P-splines are specified by model terms like `s(x,bs="cp",...)`. These bases can be used in tensor product smooths (see [te](#)).

The advantage of P-splines is the flexible way that penalty and basis order can be mixed (but see also [d.spline](#)). This often provides a useful way of ‘taming’ an otherwise poorly behaved smooth.

However, in regular use, splines with derivative based penalties (e.g. "tp" or "cr" bases) tend to result in slightly better MSE performance, presumably because the good approximation theoretic properties of splines are rather closely connected to the use of derivative penalties.

## Usage

```
S3 method for class 'ps.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'cp.smooth.spec'
smooth.construct(object, data, knots)
```

## Arguments

|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | a smooth specification object, usually generated by a term <code>s(x, bs="ps", ...)</code> or <code>s(x, bs="cp", ...)</code>                                                                                 |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| knots  | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details for further information.                                                           |

## Details

A smooth term of the form `s(x, bs="ps", m=c(2, 3))` specifies a 2nd order P-spline basis (cubic spline), with a third order difference penalty (0th order is a ridge penalty) on the coefficients. If `m` is a single number then it is taken as the basis order and penalty order. The default is the 'cubic spline like' `m=c(2, 2)`.

The default basis dimension, `k`, is the larger of 10 and `m[1]+1` for a "ps" terms and the larger of 10 and `m[1]` for a "cp" term. `m[1]+1` and `m[1]` are the lower limits on basis dimension for the two types.

If knots are supplied, then the number of knots should be one more than the basis dimension (i.e. `k+1`) for a "cp" smooth. For the "ps" basis the number of supplied knots should be `k + m[1] + 2`, and the range of the middle `k-m[1]` knots should include all the covariate values. See example.

Alternatively, for both types of smooth, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (Don't make this range too wide, however, or you can end up with no information about some basis coefficients, because the corresponding basis functions have a span that includes no data!). Note that P-splines don't make much sense with uneven knot spacing.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior `k-m[1]` knots). Such extrapolation is not allowed in basis construction, but is when predicting.

For the "ps" basis it is possible to set flags in the smooth specification object, requesting setup according to the SCOP-spline monotonic smoother construction of Pya and Wood (2015). As yet this is not supported by any modelling functions in `mgcv` (see package `scam`). Similarly it is possible to set a `deriv` flag in a smooth specification or smooth object, so that a model or prediction matrix produces the requested derivative of the spline, rather than evaluating it. See examples below.

## Value

An object of class "pspline.smooth" or "cp.smooth". See [smooth.construct](#), for the elements that this object will contain.

```

---

smooth.construct.re.smooth.spec

*Simple random effects in GAMs*

---

## Description

`gam` can deal with simple independent random effects, by exploiting the link between smooths and random effects to treat random effects as smooths. `s(x,bs="re")` implements this. Such terms can have any number of predictors, which can be any mixture of numeric or factor variables. The terms produce a parametric interaction of the predictors, and penalize the corresponding coefficients with a multiple of the identity matrix, corresponding to an assumption of i.i.d. normality. See details.

## Usage

```

S3 method for class 're.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'random.effect'
Predict.matrix(object, data)

```

## Arguments

|        |                                                                                                                                                                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | For the <code>smooth.construct</code> method a smooth specification object, usually generated by a term <code>s(x,...,bs="re",.)</code> . For the <code>predict.Matrix</code> method an object of class "random.effect" produced by the <code>smooth.construct</code> method. |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|       |                                                                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data  | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| knots | generically a list containing any knots supplied for basis setup — unused at present.                                                                                                                         |

## Details

Exactly how the random effects are implemented is best seen by example. Consider the model term `s(x, z, bs="re")`. This will result in the model matrix component corresponding to `~x:z-1` being added to the model matrix for the whole model. The coefficients associated with the model matrix component are assumed i.i.d. normal, with unknown variance (to be estimated). This assumption is equivalent to an identity penalty matrix (i.e. a ridge penalty) on the coefficients. Because such a penalty is full rank, random effects terms do not require centering constraints.

If the nature of the random effect specification is not clear, consider a couple more examples: `s(x, bs="re")` results in `model.matrix(~x-1)` being appended to the overall model matrix, while `s(x, v, w, bs="re")` would result in `model.matrix(~x:v:w-1)` being appended to the model matrix. In both cases the corresponding model coefficients are assumed i.i.d. normal, and are hence subject to ridge penalties.

Some models require differences between the coefficients corresponding to different levels of the same random effect. See [linear.functional.terms](#) for how to implement this.

If the random effect precision matrix is of the form  $\sum_j \lambda_j S_j$  for known matrices  $S_j$  and unknown parameters  $\lambda_j$ , then a list containing the  $S_j$  can be supplied in the `xt` argument of [s](#). In this case an array rank should also be supplied in `xt` giving the ranks of the  $S_j$  matrices. See simple example below.

Note that smooth ids are not supported for random effect terms. Unlike most smooth terms, side conditions are never applied to random effect terms in the event of nesting (since they are identifiable without side conditions).

Random effects implemented in this way do not exploit the sparse structure of many random effects, and may therefore be relatively inefficient for models with large numbers of random effects, when `gamm4` or [gamm](#) may be better alternatives. Note also that [gam](#) will not support models with more coefficients than data.

The situation in which factor variable random effects intentionally have unobserved levels requires special handling. You should set `drop.unused.levels=FALSE` in the model fitting function, [gam](#), [bam](#) or [gamm](#), having first ensured that any fixed effect factors do not contain unobserved levels.

The implementation is designed so that supplying random effect factor levels to [predict.gam](#) that were not levels of the factor when fitting, will result in the corresponding random effect (or interactions involving it) being set to zero (with zero standard error) for prediction. See [random.effects](#) for an example. This is achieved by the `Predict.matrix` method zeroing any rows of the prediction matrix involving factors that are NA. [predict.gam](#) will set any factor observation to NA if it is a level not present in the fit data.

## Value

An object of class "random.effect" or a matrix mapping the coefficients of the random effect to the random effects themselves.

---

smooth.construct.so.smooth.spec

*Soap film smoother constructor*

---

## Description

Sets up basis functions and wigglyness penalties for soap film smoothers (Wood, Bravington and Hedley, 2008). Soap film smoothers are based on the idea of constructing a 2-D smooth as a film of soap connecting a smoothly varying closed boundary. Unless smoothing very heavily, the film is distorted towards the data. The smooths are designed not to smooth across boundary features (peninsulas, for example).

The `so` version sets up the full smooth. The `sf` version sets up just the boundary interpolating soap film, while the `sw` version sets up the wiggly component of a soap film (zero on the boundary). The latter two are useful for forming tensor products with soap films, and can be used with [gamm](#) and [gamm4](#). To use these to simply set up a basis, then call via the wrapper [smooth.construct2](#) or [smoothCon](#).

## Usage

```
S3 method for class 'so.smooth.spec'
smooth.construct(object,data,knots)
S3 method for class 'sf.smooth.spec'
smooth.construct(object,data,knots)
S3 method for class 'sw.smooth.spec'
smooth.construct(object,data,knots)
```

## Arguments

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b> | A smooth specification object as produced by a <code>s(...,bs="so",xt=list(bnd=bnd,...))</code> term in a gam formula. Note that the <code>xt</code> argument to <code>s</code> <i>must</i> be supplied, and should be a list, containing at least a boundary specification list (see details). <code>xt</code> may also contain various options controlling the boundary smooth (see details), and PDE solution grid. The dimension of the bases for boundary loops is specified via the <code>k</code> argument of <code>s</code> , either as a single number to be used for each boundary loop, or as a vector of different basis dimensions for the various boundary loops. |
| <b>data</b>   | A list or data frame containing the arguments of the smooth.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>knots</b>  | list or data frame with two named columns specifying the knot locations within the boundary. The column names should match the names of the arguments of the smooth. The number of knots defines the <i>interior</i> basis dimension (i.e. it is <i>not</i> supplied via argument <code>k</code> of <code>s</code> ).                                                                                                                                                                                                                                                                                                                                                           |

## Details

For soap film smooths the following *must* be supplied:

**k** the basis dimension for each boundary loop smooth.

**xt\$bnd** the boundary specification for the smooth.

**knots** the locations of the interior knots for the smooth.

When used in a GAM then `k` and `xt` are supplied via `s` while `knots` are supplied in the `knots` argument of `gam`.

The `bnd` element of the `xt` list is a list of lists (or data frames), specifying the loops that define the boundary. Each boundary loop list must contain 2 columns giving the co-ordinates of points defining a boundary loop (when joined sequentially by line segments). Loops should not intersect (not checked). A point is deemed to be in the region of interest if it is interior to an odd number of boundary loops. Each boundary loop list may also contain a column `f` giving known boundary conditions on a loop.

The `bndSpec` element of `xt`, if non-NULL, should contain

**bs** the type of cyclic smoothing basis to use: one of "cc" and "cp". If not "cc" then a cyclic p-spline is used, and argument `m` must be supplied.

**knot.space** set to "even" to get even knot spacing with the "cc" basis.

**m** 1 or 2 element array specifying order of "cp" basis and penalty.

Currently the code will not deal with more than one level of nesting of loops, or with separate loops without an outer enclosing loop: if there are known boundary conditions (identifiability constraints get awkward).

Note that the function `locator` provides a simple means for defining boundaries graphically, using something like `bnd <- as.data.frame(locator(type="l"))`, after producing a plot of the domain of interest (right click to stop). If the real boundary is very complicated, it is probably better to use a simpler smooth boundary enclosing the true boundary, which represents the major boundary features that you don't want to smooth across, but doesn't follow every tiny detail.

Model set up, and prediction, involves evaluating basis functions which are defined as the solution to PDEs. The PDEs are solved numerically on a grid using sparse matrix methods, with bilinear interpolation used to obtain values at any location within the smoothing domain. The dimension of the PDE solution grid can be controlled via element `nmax` (default 200) of the list supplied as argument `xt` of `s` in a `gam` formula: it gives the number of cells to use on the longest grid side.

A little theory: the soap film smooth  $f(x, y)$  is defined as the solution of

$$f_{xx} + f_{yy} = g$$

subject to the condition that  $f = s$ , on the boundary curve, where  $s$  is a smooth function (usually a cyclic penalized regression spline). The function  $g$  is defined as the solution of

$$g_{xx} + g_{yy} = 0$$

where  $g = 0$  on the boundary curve and  $g(x_k, y_k) = c_k$  at the 'knots' of the surface; the  $c_k$  are model coefficients.

In the simplest case, estimation of the coefficients of  $f$  (boundary coefficients plus  $c_k$ 's) is by minimization of

$$\|z - f\|^2 + \lambda_s J_s(s) + \lambda_f J_f(f)$$

where  $J_s$  is usually some cubic spline type wiggleness penalty on the boundary smooth and  $J_f$  is the integral of  $(f_{xx} + f_{yy})^2$  over the interior of the boundary. Both penalties can be expressed as quadratic forms in the model coefficients. The  $\lambda$ 's are smoothing parameters, selectable by GCV, REML, AIC, etc.  $z$  represents noisy observations of  $f$ .

## Value

A list with all the elements of object plus

|                   |                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>sd</code>   | A list defining the PDE solution grid and domain boundary, and including the sparse LU factorization of the PDE coefficient matrix. |
| <code>X</code>    | The model matrix: this will have an "offset" attribute, if there are any known boundary conditions.                                 |
| <code>S</code>    | List of smoothing penalty matrices (in smallest non-zero submatrix form).                                                           |
| <code>irng</code> | A vector of scaling factors that have been applied to the model matrix, to ensure nice conditioning.                                |

In addition there are all the elements usually added by `smooth.construct` methods.

## WARNINGS

Soap film smooths are quite specialized, and require more setup than most smoothers (e.g. you have to supply the boundary and the interior knots, plus the boundary smooth basis dimension(s)). It is worth looking at the reference.

smooth.construct.sos.smooth.spec

*Splines on the sphere*

---

## Description

`gam` can use isotropic smooths on the sphere, via terms like `s(la,lo,bs="sos",m=2,k=100)`. There must be exactly 2 arguments to such a smooth. The first is taken to be latitude (in degrees) and the second longitude (in degrees). `m` (default 0) is an integer in the range -1 to 4 determining the order of the penalty used. For  $m > 0$ ,  $(m+2)/2$  is the penalty order, with  $m=2$  equivalent to the usual second derivative penalty.  $m=0$  signals to use the 2nd order spline on the sphere, computed by Wendelberger's (1981) method.  $m = -1$  results in a [Duchon.spline](#) being used (with  $m=2$  and  $s=1/2$ ), following an unpublished suggestion of Jean Duchon.

`k` (default 50) is the basis dimension.

## Usage

```

S3 method for class 'sos.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'sos.smooth'
Predict.matrix(object, data)

```

## Arguments

|                     |                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a smooth specification object, usually generated by a term <code>s(...,bs="sos",...)</code> .                                                                                                                 |
| <code>data</code>   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| <code>knots</code>  | a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be NULL                                                                                   |

## Details

For  $m > 0$ , the smooths implemented here are based on the pseudosplines on the sphere of Wahba (1981) (there is a correction of table 1 in 1982, but the correction has a misprint in the definition of A — the A given in the 1981 paper is correct). For  $m = 0$  (default) then a second order spline on the sphere is used which is the analogue of a second order thin plate spline in 2D: the computation is based on Chapter 4 of Wendelberger, 1981. Optimal low rank approximations are obtained using exactly the approach given in Wood (2003). For  $m = -1$  a smooth of the general type discussed in Duchon (1977) is used: the sphere is embedded in a 3D Euclidean space, but smoothing employs a penalty based on second derivatives (so that locally as the smoothing parameter tends to zero we recover a "normal" thin plate spline on the tangent space). This is an unpublished suggestion of Jean Duchon.  $m = -2$  is the same but with first derivative penalization.

Note that the null space of the penalty is always the space of constant functions on the sphere, whatever the order of penalty.

This class has a plot method, with 3 schemes. `scheme==0` plots one hemisphere of the sphere, projected onto a circle. The plotting sphere has the north pole at the top, and the 0 meridian running down the middle of the plot, and towards the viewer. The smoothing sphere is rotated within the plotting sphere, by specifying the location of its pole in the co-ordinates of the viewing sphere. `theta`, `phi` give the longitude and latitude of the smoothing sphere pole within the plotting sphere (in plotting sphere co-ordinates). (You can visualize the smoothing sphere as a globe, free to rotate within the fixed transparent plotting sphere.) The value of the smooth is shown by a heat map overlaid with a contour plot. `lat`, `lon` gridlines are also plotted.

`scheme==1` is as `scheme==0`, but in black and white, without the image plot. `scheme>1` calls the default plotting method with `scheme` decremented by 2.

## Value

An object of class "`sos.smooth`". In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|                 |                                                                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>Xu</code> | A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations). |
| <code>UZ</code> | The matrix mapping the parameters of the reduced rank spline back to the parameters of a full spline.                                |

## Author(s)

Simon Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>, with help from Grace Wahba ( $m=0$  case) and Jean Duchon ( $m = -1$  case).

smooth.construct.sz.smooth.spec

*Constrained factor smooth interactions in GAMs*

## Description

Factor smooth interactions constructed to exclude main effects (and lower order factor smooth interactions). A smooth is constructed for each combination of the supplied factor levels. By appropriate application of sum to zero contrasts to equivalent smooth coefficients across factor levels, the required exclusion of lower order effects is achieved.

See [factor.smooth](#) for alternative factor smooth interactions.

## Usage

```
S3 method for class 'sz.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'sz.interaction'
Predict.matrix(object, data)
```

## Arguments

|        |                                                                                                                                                                                                                                           |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | For the smooth.construct method a smooth specification object, usually generated by a term <code>s(x, ..., bs="sz", )</code> . For the predict.Matrix method an object of class "sz.interaction" produced by the smooth.construct method. |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to object\$term.                                                                                                              |
| knots  | a list containing any knots supplied for smooth basis setup.                                                                                                                                                                              |

## Details

This class produces a smooth for each combination of the levels of the supplied factor variables. `s(fac, x, bs="sz")` produces a smooth of `x` for each level of `fac`, for example. The smooths are constrained to represent deviations from the main effect smooth, so that models such as

$$g(\mu_i) = f(x_i) + f_{k(i)}(x_i)$$

can be estimated in an identifiable manner, where  $k(i)$  indicates the level of some factor that applies for the  $i$ th observation. Identifiability in this case is ensured by constraining the coefficients of the splines representing the  $f_k$ . In particular if  $\beta_{ki}$  is the  $i$ th coefficient of  $f_k$  then the constraints are  $\sum_k \beta_{ki} = 0$ .

Such sum to zero constraints are implemented using sum to zero contrasts: identity matrices with an extra row of -1s appended. Consider the case of a single factor first. The model matrix corresponding to a smooth per factor level is the row tensor product (see [tensor.prod.model.matrix](#)) of the model matrix for the factor, and the model matrix for the smooth. The contrast matrix is then the Kronecker product of the sum to zero contrast for the factor, and an identity matrix of dimension determined by the number of coefficients of the smooth.

If there are multiple factors then the overall model matrix is the row Kronecker product of all the factor model matrices and the smooth, while the contrast is the Kronecker product of all the sum-to-zero contrasts for the factors and a final identity matrix. Notice that this construction means that the main effects (and any interactions) of the factors are included in the factor level dependent smooths. In other words the individual smooths are not each centered. This means that adding main effects or interactions of the factors will lead to a rank deficient model.

The terms can have a smoothing parameter per smooth, or a single smoothing parameter for all the smooths. The latter is specified by giving the smooth term an id. e.g. `s(fac,x,bs="sz",id=1)`.

The basis for the smooths can be selected by supplying a list as the `xt` argument to [s](#), with a `bs` item. e.g. `s(fac,x,xt=list(bs="cr"))` selects the "cr" basis. The default is "tp"

The plot method for this class has two schemes. `scheme==0` is in colour, while `scheme==1` is black and white. Currently it only works for 1D smooths.

## Value

An object of class "sz.interaction" or a matrix mapping the coefficients of the factor smooth interaction to the smooths themselves.

## Details

Tensor product smooths are smooths of several variables which allow the degree of smoothing to be different with respect to different variables. They are useful as smooth interaction terms, as they are invariant to linear rescaling of the covariates, which means, for example, that they are insensitive to the measurement units of the different covariates. They are also useful whenever isotropic smoothing is inappropriate. See [t2](#), [te](#), [smooth.construct](#) and [smooth.terms](#). The construction employed here produces tensor smooths for which the smoothing penalties are non-overlapping portions of the identity matrix. This makes their estimation by mixed modelling software rather easy.

## Value

An object of class `"t2.smooth"`.

## see ?gam

---

smooth.construct.tp.smooth.spec*Penalized thin plate regression splines in GAMs*

---

**Description**

[gam](#) can use isotropic smooths of any number of variables, specified via terms like `s(x, z, bs="tp", m=3)` (or just `s(x, z)` as this is the default basis). These terms are based on thin plate regression splines. `m` specifies the order of the derivatives in the thin plate spline penalty.

If `m` is a vector of length 2 and the second element is zero, then the penalty null space of the smooth is not included in the smooth: this is useful if you need to test whether a smooth could be replaced by a linear term, or construct models with odd nesting structures.

Thin plate regression splines are constructed by starting with the basis and penalty for a full thin plate spline and then truncating this basis in an optimal manner, to obtain a low rank smoother. Details are given in Wood (2003). One key advantage of the approach is that it avoids the knot placement problems of conventional regression spline modelling, but it also has the advantage that smooths of lower rank are nested within smooths of higher rank, so that it is legitimate to use conventional hypothesis testing methods to compare models based on pure regression splines. Note that the basis truncation does not change the meaning of the thin plate spline penalty (it penalizes exactly what it would have penalized for a full thin plate spline).

The t.p.r.s. basis and penalties can become expensive to calculate for large datasets. For this reason the default behaviour is to randomly subsample `max.knots` unique data locations if there are more than `max.knots` such, and to use the sub-sample for basis construction. The sampling is always done with the same random seed to ensure repeatability (does not reset R RNG). `max.knots` is 2000, by default. Both seed and `max.knots` can be modified using the `xt` argument to `s`. Alternatively the user can supply knots from which to construct a basis.

The "ts" smooths are t.p.r.s. with the penalty modified so that the term is shrunk to zero for high enough smoothing parameter, rather than being shrunk towards a function in the penalty null space (see details).

**Usage**

```
S3 method for class 'tp.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'ts.smooth.spec'
smooth.construct(object, data, knots)
```

## Details

The default basis dimension for this class is  $k=M+k.def$  where  $M$  is the null space dimension (dimension of unpenalized function space) and  $k.def$  is 8 for dimension 1, 27 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The default is to set  $m$  (the order of derivative in the thin plate spline penalty) to the smallest value satisfying  $2m > d+1$  where  $d$  is the number of covariates of the term: this yields 'visually smooth' functions. In any case  $2m > d$  must be satisfied.

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use [smooth.construct2](#).

For these classes the specification object will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 'knots' from which to produce a tprs basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to [s](#). This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing).

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the `tp` basis can be time-consuming. The user can retain most of the advantages of the t.p.r.s. approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension,  $k$ . This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the t.p.r.s. basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension,  $k$ . For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

The shrinkage version of the smooth, eigen-decomposes the wiggleness penalty matrix, and sets its zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

## Value

An object of class `"tprs.smooth"` or `"ts.smooth"`. In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|                      |                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| shift                | A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term. |
| Xu                   | A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).                                                          |
| UZ                   | The matrix mapping the t.p.r.s. parameters back to the parameters of a full thin plate spline.                                                                                                |
| null.space.dimension | The dimension of the space of functions that have zero wiggleness according to the wiggleness penalty for this term.                                                                          |

|-------------|---------------------------------------------------------------------------------|
| smooth.info | <i>Generic function to provide extra information about smooth specification</i> |
|-------------|---------------------------------------------------------------------------------|

---

## Description

Takes a smooth specification object and adds extra basis specific information to it before smooth constructor called. Default method returns supplied object unmodified.

## Usage

```
smooth.info(object)
```

## Arguments

object            is a smooth specification object

## Details

Sometimes it is necessary to know something about a smoother before it is constructed, beyond what is in the initial smooth specification object. For example, some smooth terms could be set up as tensor product smooths and it is useful for [bam](#) to take advantage of this when discrete covariate methods are used. However, [bam](#) needs to know whether a smoother falls into this category before it is constructed in order to discretize its covariates marginally instead of jointly. Rather than [bam](#) having a hard coded list of such smooth classes it is preferable for the smooth specification object to report this themselves. `smooth.info` method functions are the means for achieving this. When interpreting a gam formula the `smooth.info` function is applied to each smooth specification object as soon as it is produced (in `interpret.gam0`).

## Value

A smooth specification object, which may be modified in some way.

smooth.terms

*Smooth terms in GAM*

---

## Description

Smooth terms are specified in a `gam` formula using `s`, `te`, `ti` and `t2` terms. Various smooth classes are available, for different modelling tasks, and users can add smooth classes (see `user.defined.smooth`). What defines a smooth class is the basis used to represent the smooth function and quadratic penalty (or multiple penalties) used to penalize the basis coefficients in order to control the degree of smoothness. Smooth classes are invoked directly by `s` terms, or as building blocks for tensor product smoothing via `te`, `ti` or `t2` terms (only smooth classes with single penalties can be used in tensor products). The smooths built into the `mgcv` package are all based one way or another on low rank versions of splines. For the full rank versions see Wahba (1990).

Note that smooths can be used rather flexibly in `gam` models. In particular the linear predictor of the GAM can depend on (a discrete approximation to) any linear functional of a smooth term, using by variables and the ‘summation convention’ explained in `linear.functional.terms`.

The single penalty built in smooth classes are summarized as follows

**Thin plate regression splines** `bs="tp"`. These are low rank isotropic smoothers of any number of covariates. By isotropic is meant that rotation of the covariate co-ordinate system will not change the result of smoothing. By low rank is meant that they have far fewer coefficients than there are data to smooth. They are reduced rank versions of the thin plate splines and use the thin plate spline penalty. They are the default smooth for `s` terms because there is a defined sense in which they are the optimal smoother of any given basis dimension/rank (Wood, 2003). Thin plate regression splines do not have ‘knots’ (at least not in any conventional sense): a truncated eigen-decomposition is used to achieve the rank reduction. See `tpsr` for further details.

`bs="ts"` is as `"tp"` but with a modification to the smoothing penalty, so that the null space is also penalized slightly and the whole term can therefore be shrunk to zero.

**Duchon splines** `bs="ds"`. These generalize thin plate splines. In particular, for any given number of covariates they allow lower orders of derivative in the penalty than thin plate splines (and hence a smaller null space). See `Duchon.spline` for further details.

**Cubic regression splines** `bs="cr"`. These have a cubic spline basis defined by a modest sized set of knots spread evenly through the covariate values. They are penalized by the conventional integrated square second derivative cubic spline penalty. For details see `cubic.regression.spline` and e.g. Wood (2017).

`bs="cs"` specifies a shrinkage version of `"cr"`.

`bs="cc"` specifies a cyclic cubic regression splines (see `cyclic.cubic.spline`). i.e. a penalized cubic regression splines whose ends match, up to second derivative.

**Splines on the sphere** `bs="sos"`. These are two dimensional splines on a sphere. Arguments are latitude and longitude, and they are the analogue of thin plate splines for the sphere. Useful for data sampled over a large portion of the globe, when isotropy is appropriate. See [Spherical.Spline](#) for details.

**B-splines** `bs="bs"`. B-spline basis with integrated squared derivative penalties. The order of basis and penalty can be chosen separately, and several penalties of different orders can be applied. Somewhat like a derivative penalty version of P-splines. See [b.spline](#) for details.

**P-splines** `bs="ps"`. These are P-splines as proposed by Eilers and Marx (1996). They combine a B-spline basis, with a discrete penalty on the basis coefficients, and any sane combination of penalty and basis order is allowed. Although this penalty has no exact interpretation in terms of function shape, in the way that the derivative penalties do, P-splines perform almost as well as conventional splines in many standard applications, and can perform better in particular cases where it is advantageous to mix different orders of basis and penalty.

`bs="cp"` gives a cyclic version of a P-spline (see [cyclic.p.spline](#)).

**Random effects** `bs="re"`. These are parametric terms penalized by a ridge penalty (i.e. the identity matrix). When such a smooth has multiple arguments then it represents the parametric interaction of these arguments, with the coefficients penalized by a ridge penalty. The ridge penalty is equivalent to an assumption that the coefficients are i.i.d. normal random effects. See [smooth.construct.re.smooth.spec](#).

**Markov Random Fields** `bs="mrf"`. These are popular when space is split up into discrete contiguous geographic units (districts of a town, for example). In this case a simple smoothing penalty is constructed based on the neighbourhood structure of the geographic units. See [mrf](#) for details and an example.

**Gaussian process smooths** `bs="gp"`. Gaussian process models with a variety of simple correlation functions can be represented as smooths. See [gp.smooth](#) for details.

**Soap film smooths** `bs="so"` (actually not single penalized, but `bs="sw"` and `bs="sf"` allows splitting into single penalty components for use in tensor product smoothing). These are finite area smoothers designed to smooth within complicated geographical boundaries, where the boundary matters (e.g. you do not want to smooth across boundary features). See [soap](#) for details.

Broadly speaking the default penalized thin plate regression splines tend to give the best MSE performance, but they are slower to set up than the other bases. The knot based penalized cubic regression splines (with derivative based penalties) usually come next in MSE performance, with the P-splines doing just a little worse. However the P-splines are useful in non-standard situations.

All the preceding classes (and any user defined smooths with single penalties) may be used as marginal bases for tensor product smooths specified via [te](#), [ti](#) or [t2](#) terms. Tensor product smooths are smooth functions of several variables where the basis is built up from tensor products of bases for smooths of fewer (usually one) variable(s) (marginal bases). The multiple penalties for these smooths are produced automatically from the penalties of the marginal smooths. Wood (2006) and Wood, Scheipl and Faraway (2012), give the general recipe for these constructions.

**te** `te` smooths have one penalty per marginal basis, each of which is interpretable in a similar way to the marginal penalty from which it is derived. See Wood (2006).

**ti** `ti` smooths exclude the basis functions associated with the ‘main effects’ of the marginal smooths, plus interactions other than the highest order specified. These provide a stable an interpretable way of specifying models with main effects and interactions. For example if we are interested in linear predictor  $f_1(x) + f_2(z) + f_3(x, z)$ , we might use model formula `y~s(x)+s(z)+ti(x,z)` or `y~ti(x)+ti(z)+ti(x,z)`. A similar construction involving `te` terms instead will be much less statistically stable.

- t2** t2 uses an alternative tensor product construction that results in more penalties each having a simple non-overlapping structure allowing use with the `gamm4` package. It is a natural generalization of the SS-ANOVA construction, but the penalties are a little harder to interpret. See Wood, Scheipl and Faraway (2012/13).

Tensor product smooths often perform better than isotropic smooths when the covariates of a smooth are not naturally on the same scale, so that their relative scaling is arbitrary. For example, if smoothing with respect to time and distance, an isotropic smoother will give very different results if the units are cm and minutes compared to if the units are metres and seconds: a tensor product smooth will give the same answer in both cases (see [te](#) for an example of this). Note that `te` terms are knot based, and the thin plate splines seem to offer no advantage over cubic or P-splines as marginal bases.

Some further specialist smoothers that are not suitable for use in tensor products are also available.

**Adaptive smoothers** `bs="ad"` Univariate and bivariate adaptive smooths are available (see [adaptive.smooth](#)). These are appropriate when the degree of smoothing should itself vary with the covariates to be smoothed, and the data contain sufficient information to be able to estimate the appropriate variation. Because this flexibility is achieved by splitting the penalty into several ‘basis penalties’ these terms are not suitable as components of tensor product smooths, and are not supported by `gamm`.

**Factor smooth interactions** `bs="sz"` Smooth factor interactions (see [factor.smooth](#)) are often produced using by variables (see [gam.models](#)), but it is often desirable to include smooths which represent the deviations from some main effect smooth that apply for each level of a factor (or combination of factors). See [smooth.construct.sz.smooth.spec](#) for details.

**Random factor smooth interactions** `bs="fs"` A special smoother class (see [smooth.construct.fs.smooth.spec](#)) is available for the case in which a smooth is required at each of a large number of factor levels (for example a smooth for each patient in a study), and each smooth should have the same smoothing parameter. The “fs” smoothers are set up to be efficient when used with `gamm`, and have penalties on each null sapce component (i.e. they are fully ‘random effects’).

|---------------|----------------------------------------------------------------------------|
| smooth2random | <i>Convert a smooth to a form suitable for estimating as random effect</i> |
|---------------|----------------------------------------------------------------------------|

---

### Description

A generic function for converting mgcv smooth objects to forms suitable for estimation as random effects by e.g. lme. Exported mostly for use by other package developers.

### Usage

```
smooth2random(object, vnames, type=1)
```

### Arguments

|                     |                                                                                |
|---------------------|--------------------------------------------------------------------------------|
| <code>object</code> | an mgcv smooth object.                                                         |
| <code>vnames</code> | a vector of names to avoid as dummy variable names in the random effects form. |
| <code>type</code>   | 1 for lme, otherwise lmer.                                                     |

### Details

There is a duality between smooths and random effects which means that smooths can be estimated using mixed modelling software. This function converts standard mgcv smooth objects to forms suitable for estimation by lme, for example. A service routine for `gamm` exported for use by package developers. See examples for creating prediction matrices for new data, corresponding to the random and fixed effect matrices returned when `type=2`.

### Value

A list.

|                   |                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rand</code> | a list of random effects, including grouping factors, and a fixed effects matrix. Grouping factors, model matrix and model matrix name attached as attributes, to each element. Alternatively, for <code>type=2</code> a list of random effect model matrices, each corresponding to an i.i.d. Gaussian random effect with a single variance component. |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|         |                                                                                                                                                                                                             |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| trans.D | A vector, trans.D, that transforms coefs, in order [rand1, rand2,... fix] back to original parameterization. If null, then taken as vector of ones. <code>b.original = trans.U %*% (trans.D*b.fit)</code> . |
| trans.U | A matrix, trans.U, that transforms coefs, in order [rand1, rand2,... fix] back to original parameterization. If null, then not needed. If null then taken as identity.                                      |
| Xf      | A matrix for the fixed effects, if any.                                                                                                                                                                     |
| fixed   | TRUE/FALSE, indicating if term was unpenalized or not. If unpenalized then other stuff may not be returned (it's not a random effect).                                                                      |
| rind    | an index vector such that if br is the vector of random coefficients for the term, <code>br[rind]</code> is the coefs in order for this term.                                                               |
| pen.ind | index of which penalty penalizes each coefficient: 0 for unpenalized.                                                                                                                                       |

**Examples**

```
Simple type 1 'lme' style...
library(mgcv)
x <- runif(30)
sm <- smoothCon(s(x),data.frame(x=x))[[1]]
smooth2random(sm,"")

Now type 2 'lme4' style...
z <- runif(30)
dat <- data.frame(x=x,z=z)
sm <- smoothCon(t2(x,z),dat)[[1]]
re <- smooth2random(sm,"",2)
str(re)

For prediction after fitting we might transform parameters back to
original parameterization using 'rind', 'trans.D' and 'trans.U',
and call PredictMat(sm,newdata) to get the prediction matrix to
multiply these transformed parameters by.
Alternatively we could obtain fixed and random effect Prediction
matrices corresponding to the results from smooth2random, which
can be used with the fit parameters without transforming them.
The following shows how...

s2rPred <- function(sm,re,data) {
 ## Function to aid prediction from smooths represented as type==2
 ## random effects. re must be the result of smooth2random(sm,...,type=2).
 X <- PredictMat(sm,data) ## get prediction matrix for new data
 ## transform to r.e. parameterization
```

```

if (!is.null(re$trans.U)) X <- X%%re$trans.U
X <- t(t(X)*re$trans.D)
re-order columns according to random effect re-ordering...
X[,re$reind] <- X[,re$pen.ind!=0]
re-order penalization index in same way
pen.ind <- re$pen.ind; pen.ind[re$reind] <- pen.ind[pen.ind>0]
start return object...
r <- list(rand=list(),Xf=X[,which(re$pen.ind==0),drop=FALSE])
for (i in 1:length(re$rand)) { ## loop over random effect matrices
 r$rand[[i]] <- X[,which(pen.ind==i),drop=FALSE]
 attr(r$rand[[i]],"s.label") <- attr(re$rand[[i]],"s.label")
}
names(r$rand) <- names(re$rand)
r
} ## s2rPred

use function to obtain prediction random and fixed effect matrices
for first 10 elements of 'dat'. Then confirm that these match the
first 10 rows of the original model matrices, as they should...

r <- s2rPred(sm,re,dat[1:10,])

smoothCon

*Prediction/Construction wrapper functions for GAM smooth terms*

## Description

Wrapper functions for construction of and prediction from smooth terms in a GAM. The purpose of the wrappers is to allow user-transparent re-parameterization of smooth terms, in order to allow identifiability constraints to be absorbed into the parameterization of each term, if required. The routine also handles ‘by’ variables and construction of identifiability constraints automatically, although this behaviour can be over-ridden.

## Usage

```

smoothCon(object,data,knots=NULL,absorb.cons=FALSE,
 scale.penalty=TRUE,n=nrow(data),dataX=NULL,
 null.space.penalty=FALSE,sparse.cons=0,
 diagonal.penalty=FALSE,apply.by=TRUE,modCon=0)
PredictMat(object,data,n=nrow(data))

```

## Arguments

|             |                                                                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object      | is a smooth specification object or a smooth object.                                                                                                                   |
| data        | A data frame, model frame or list containing the values of the (named) covariates at which the smooth term is to be evaluated. If it's a list then n must be supplied. |
| knots       | An optional data frame supplying any knot locations to be supplied for basis construction.                                                                             |
| absorb.cons | Set to TRUE in order to have identifiability constraints absorbed into the basis.                                                                                      |

|                                 |                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>scale.penalty</code>      | should the penalty coefficient matrix be scaled to have approximately the same 'size' as the inner product of the terms model matrix with itself? This can improve the performance of <code>gamm</code> fitting.                                                                                                                                                                             |
| <code>n</code>                  | number of values for each covariate, or if a covariate is a matrix, the number of rows in that matrix: must be supplied explicitly if data is a list.                                                                                                                                                                                                                                        |
| <code>dataX</code>              | Sometimes the basis should be set up using data in <code>data</code> , but the model matrix should be constructed with another set of data provided in <code>dataX</code> — <code>n</code> is assumed to be the same for both. Facilitates smooth id's.                                                                                                                                      |
| <code>null.space.penalty</code> | Should an extra penalty be added to the smooth which will penalize the components of the smooth in the penalty null space: provides a way of penalizing terms out of the model altogether.                                                                                                                                                                                                   |
| <code>apply.by</code>           | set to <code>FALSE</code> to have basis setup exactly as in default case, but to return add an additional matrix <code>X0</code> to the return object, containing the model matrix without the by variable, if a by variable is present. Useful for <code>bam</code> discrete method setup.                                                                                                  |
| <code>sparse.cons</code>        | If 0 then default sum to zero constraints are used. If -1 then sweep and drop sum to zero constraints are used (default with <code>bam</code> ). If 1 then one coefficient is set to zero as constraint for sparse smooths. If 2 then sparse coefficient sum to zero constraints are used for sparse smooths. None of these options has an effect if the smooth supplies its own constraint. |
| <code>diagonal.penalty</code>   | If <code>TRUE</code> then the smooth is reparameterized to turn the penalty into an identity matrix, with the final diagonal elements zeroed (corresponding to the penalty nullspace). May result in a matrix <code>diagRP</code> in the returned object for use by <code>PredictMat</code> .                                                                                                |
| <code>modCon</code>             | force modification of any smooth supplied constraints. 0 - do nothing. 1 - delete supplied constraints, replacing with automatically generated ones. 2 - set fit and predict constraint to predict constraint. 3 - set fit and predict constraint to fit constraint.                                                                                                                         |

## Details

These wrapper functions exist to allow smooths specified using `smooth.construct` and `Predict.matrix` method functions to be re-parameterized so that identifiability constraints are no longer required in fitting. This is done in a user transparent manner, but is typically of no importance in use of GAMs. The routine's also handle by variables and will create default identifiability constraints.

If a user defined smooth constructor handles by variables itself, then its returned smooth object should contain an object `by.done`. If this does not exist then `smoothCon` will use the default code. Similarly if a user defined `Predict.matrix` method handles by variables internally then the returned matrix should have a `"by.done"` attribute.

Default centering constraints, that terms should sum to zero over the covariates, are produced unless the smooth constructor includes a matrix `C` of constraints. To have no constraints (in which case you had better have a full rank penalty!) the matrix `C` should have no rows. There is an option to use centering constraint that generate no, or limited infill, if the smoother has a sparse model matrix.

`smoothCon` returns a list of smooths because factor by variables result in multiple copies of a smooth, each multiplied by the dummy variable associated with one factor level. `smoothCon` modifies the smooth object labels in the presence of by variables, to ensure that they are unique, it also stores the level of a by variable factor associated with a smooth, for later use by `PredictMat`.

The parameterization used by `gam` can be controlled via `gam.control`.

**Value**

From smoothCon a list of smooth objects returned by the appropriate `smooth.construct` method function. If constraints are to be absorbed then the objects will have attributes "qrc" and "nCons". "nCons" is the number of constraints. "qrc" is usually the qr decomposition of the constraint matrix (returned by `qr`), but if it is a single positive integer it is the index of the coefficient to set to zero, and if it is a negative number then this indicates that the parameters are to sum to zero.

For predictMat a matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in object.

**Examples**

```
example of using smoothCon and PredictMat to set up a basis
to use for regression and make predictions using the result
library(MASS) ## load for mcycle data.
set up a smoother...
sm <- smoothCon(s(times,k=10),data=mcycle,knots=NULL)[[1]]
use it to fit a regression spline model...
beta <- coef(lm(mcycle$accel~sm$X-1))
with(mcycle,plot(times,accel)) ## plot data
times <- seq(0,60,length=200) ## creat prediction times
Get matrix mapping beta to spline prediction at 'times'
Xp <- PredictMat(sm,data.frame(times=times))
lines(times,Xp%%beta) ## add smooth to plot

Same again but using a penalized regression spline of
rank 30....
sm <- smoothCon(s(times,k=30),data=mcycle,knots=NULL)[[1]]
E <- t(mroot(sm$S[[1]])) ## square root penalty
X <- rbind(sm$X,0.1*E) ## augmented model matrix
y <- c(mcycle$accel,rep(0,nrow(E))) ## augmented data
beta <- coef(lm(y~X-1)) ## fit penalized regression spline
Xp <- PredictMat(sm,data.frame(times=times)) ## prediction matrix
with(mcycle,plot(times,accel)) ## plot data
lines(times,Xp%%beta) ## overlay smooth
```

---

sp.vcov

---

*Extract smoothing parameter estimator covariance matrix from (RE)ML GAM fit*

---

**Description**

Extracts the estimated covariance matrix for the log smoothing parameter estimates from a (RE)ML estimated gam object, provided the fit was with a method that evaluated the required Hessian.

**Usage**

```
sp.vcov(x, edge.correct=TRUE, reg=1e-3)
```

**Arguments**

|                           |                                                                                                                                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | a fitted model object of class <code>gam</code> as produced by <code>gam()</code> .                                                                                                          |
| <code>edge.correct</code> | if the model was fitted with <code>edge.correct=TRUE</code> (see <a href="#">gam.control</a> ), then the returned covariance matrix will be for the edge corrected log smoothing parameters. |
| <code>reg</code>          | regularizer for Hessian - default is equivalent to prior variance of 1000 on log smoothing parameters.                                                                                       |

**Details**

Just extracts the inverse of the hessian matrix of the negative (restricted) log likelihood w.r.t the log smoothing parameters, if this has been obtained as part of fitting.

**Value**

A matrix corresponding to the estimated covariance matrix of the log smoothing parameter estimators, if this can be extracted, otherwise `NULL`. If the scale parameter has been (RE)ML estimated (i.e. if the method was "ML" or "REML" and the scale parameter was unknown) then the last row and column relate to the log scale parameter. If `edge.correct=TRUE` and this was used in fitting then the edge corrected smoothing parameters are in attribute `lsp` of the returned matrix.

|-----------------|--------------------------------------|
| spasm.construct | <i>Experimental sparse smoothers</i> |
|-----------------|--------------------------------------|

---

**Description**

These are experimental sparse smoothing functions, and should be left well alone!

**Usage**

```
spasm.construct(object, data)
spasm.sp(object, sp, w=rep(1, object$nobs), get.trH=TRUE, block=0, centre=FALSE)
spasm.smooth(object, X, residual=FALSE, block=0)
```

**Arguments**

|          |                                                                |
|----------|----------------------------------------------------------------|
| object   | sparse smooth object                                           |
| data     | data frame                                                     |
| sp       | smoothing parameter value                                      |
| w        | optional weights                                               |
| get.trH  | Should (estimated) trace of sparse smoother matrix be returned |
| block    | index of block, 0 for all blocks                               |
| centre   | should sparse smooth be centred?                               |
| X        | what to smooth                                                 |
| residual | apply residual operation?                                      |

**WARNING**

It is not recommended to use these yet

**Description**

There is no step.gam in package mgcv. The mgcv default for model selection is to use either prediction error criteria such as GCV, GACV, Mallows' Cp/AIC/UBRE or the likelihood based methods of REML or ML. Since the smoothness estimation part of model selection is done in this way it is logically most consistent to perform the rest of model selection in the same way. i.e. to decide which terms to include or omit by looking at changes in GCV, AIC, REML etc.

To facilitate fully automatic model selection the package implements two smooth modification techniques which can be used to allow smooths to be shrunk to zero as part of smoothness selection.

**Shrinkage smoothers** are smoothers in which a small multiple of the identity matrix is added to the smoothing penalty, so that strong enough penalization will shrink all the coefficients of the smooth to zero. Such smoothers can effectively be penalized out of the model altogether, as part of smoothing parameter estimation. 2 classes of these shrinkage smoothers are implemented: "cs" and "ts", based on cubic regression spline and thin plate regression spline smoothers (see [s](#))

**Null space penalization** An alternative is to construct an extra penalty for each smooth which penalizes the space of functions of zero wiggleness according to its existing penalties. If all the smoothing parameters for such a term tend to infinity then the term is penalized to zero, and is effectively dropped from the model. The advantage of this approach is that it can be implemented automatically for any smooth. The `select` argument to `gam` causes this latter approach to be used. Unpenalized terms (e.g. `s(x, fx=TRUE)`) remain unpenalized.

REML and ML smoothness selection are equivalent under this approach, and simulation evidence suggests that they tend to perform a little better than prediction error criteria, for model selection.

#### Examples

```
an example of GCV based model selection as
an alternative to stepwise selection, using
shrinkage smoothers...
library(mgcv)
set.seed(0); n <- 400
dat <- gamSim(1, n=n, scale=2)
dat$x4 <- runif(n, 0, 1)
dat$x5 <- runif(n, 0, 1)
attach(dat)
Note the increased gamma parameter below to favour
slightly smoother models...
b <- gam(y~s(x0, bs="ts")+s(x1, bs="ts")+s(x2, bs="ts")+
 s(x3, bs="ts")+s(x4, bs="ts")+s(x5, bs="ts"), gamma=1.4)
summary(b)
plot(b, pages=1)

Same again using REML/ML
b <- gam(y~s(x0, bs="ts")+s(x1, bs="ts")+s(x2, bs="ts")+
 s(x3, bs="ts")+s(x4, bs="ts")+s(x5, bs="ts"), method="REML")
summary(b)
plot(b, pages=1)

And once more, but using the null space penalization
b <- gam(y~s(x0, bs="cr")+s(x1, bs="cr")+s(x2, bs="cr")+
```

```

s(x3,bs="cr")+s(x4,bs="cr")+s(x5,bs="cr"),
method="REML",select=TRUE)
summary(b)
plot(b,pages=1)

detach(dat);rm(dat)

```

summary.gam

*Summary for a GAM fit***Description**

Takes a fitted gam object produced by `gam()` and produces various useful summaries from it. (See [sink](#) to divert output to a file.)

**Usage**

```

S3 method for class 'gam'
summary(object, dispersion=NULL, freq=FALSE, re.test=TRUE, ...)

S3 method for class 'summary.gam'
print(x,digits = max(3, getOption("digits") - 3),
 signif.stars = getOption("show.signif.stars"),...)

```

**Arguments**

|                           |                                                                                                                                                                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>       | a fitted gam object as produced by <code>gam()</code> .                                                                                                                                                                              |
| <code>x</code>            | a <code>summary.gam</code> object produced by <code>summary.gam()</code> .                                                                                                                                                           |
| <code>dispersion</code>   | A known dispersion parameter. NULL to use estimate or default (e.g. 1 for Poisson).                                                                                                                                                  |
| <code>freq</code>         | By default p-values for parametric terms are calculated using the Bayesian estimated covariance matrix of the parameter estimators. If this is set to TRUE then the frequentist covariance matrix of the parameters is used instead. |
| <code>re.test</code>      | Should tests be performed for random effect terms (including any term with a zero dimensional null space)? For large models these tests can be computationally expensive.                                                            |
| <code>digits</code>       | controls number of digits printed in output.                                                                                                                                                                                         |
| <code>signif.stars</code> | Should significance stars be printed alongside output.                                                                                                                                                                               |
| <code>...</code>          | other arguments.                                                                                                                                                                                                                     |

**Details**

Model degrees of freedom are taken as the trace of the influence (or hat) matrix  $\mathbf{A}$  for the model fit. Residual degrees of freedom are taken as number of data minus model degrees of freedom. Let  $\mathbf{P}_i$  be the matrix giving the parameters of the  $i$ th smooth when applied to the data (or pseudodata in the generalized case) and let  $\mathbf{X}$  be the design matrix of the model. Then  $tr(\mathbf{X}\mathbf{P}_i)$  is the edf for the  $i$ th term. Clearly this definition causes the edf's to add up properly! An alternative version of EDF is more appropriate for p-value computation, and is based on the trace of  $2\mathbf{A} - \mathbf{A}\mathbf{A}$ .

`print.summary.gam` tries to print various bits of summary information useful for term selection in a pretty way.

P-values for smooth terms are usually based on a test statistic motivated by an extension of Nychka's (1988) analysis of the frequentist properties of Bayesian confidence intervals for smooths (Marra and Wood, 2012). These have better frequentist performance (in terms of power and distribution under the null) than the alternative strictly frequentist approximation. When the Bayesian intervals have good across the function properties then the p-values have close to the correct null distribution and reasonable power (but there are no optimality results for the power). Full details are in Wood (2013b), although what is computed is actually a slight variant in which the components of the test statistic are weighted by the iterative fitting weights.

Note that for terms with no unpenalized terms (such as Gaussian random effects) the Nychka (1988) requirement for smoothing bias to be substantially less than variance breaks down (see e.g. appendix of Marra and Wood, 2012), and this results in incorrect null distribution for p-values computed using the above approach. In this case it is necessary to use an alternative approach designed for random effects variance components, and this is done. See Wood (2013a) for details: the test is based on a likelihood ratio statistic (with the reference distribution appropriate for the null hypothesis on the boundary of the parameter space).

All p-values are computed without considering uncertainty in the smoothing parameter estimates.

In simulations the p-values have best behaviour under ML smoothness selection, with REML coming second. In general the p-values behave well, but neglecting smoothing parameter uncertainty means that they may be somewhat too low when smoothing parameters are highly uncertain. High uncertainty happens in particular when smoothing parameters are poorly identified, which can occur with nested smooths or highly correlated covariates (high concurvity).

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (`freq=TRUE`), since the parametric terms themselves are usually unpenalized. Default P-values for parameteric terms that are penalized using the `paraPen` argument will not be good. However if such terms represent conventional random effects with full rank penalties, then setting `freq=TRUE` is appropriate.

## Value

`summary.gam` produces a list of summary information for a fitted `gam` object.

|                      |                                                                                                                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>p.coeff</code> | is an array of estimates of the strictly parametric model coefficients.                                                                                                                                                                                                                    |
| <code>p.t</code>     | is an array of the <code>p.coeff</code> 's divided by their standard errors.                                                                                                                                                                                                               |
| <code>p.pv</code>    | is an array of p-values for the null hypothesis that the corresponding parameter is zero. Calculated with reference to the t distribution with the estimated residual degrees of freedom for the model fit if the dispersion parameter has been estimated, and the standard normal if not. |
| <code>m</code>       | The number of smooth terms in the model.                                                                                                                                                                                                                                                   |
| <code>chi.sq</code>  | An array of test statistics for assessing the significance of model smooth terms. See details.                                                                                                                                                                                             |
| <code>s.pv</code>    | An array of approximate p-values for the null hypotheses that each smooth term is zero. Be warned, these are only approximate.                                                                                                                                                             |
| <code>se</code>      | array of standard error estimates for all parameter estimates.                                                                                                                                                                                                                             |
| <code>r.sq</code>    | The adjusted r-squared for the model. Defined as the proportion of variance explained, where original variance and residual variance are both estimated using unbiased estimators. This quantity can be negative if your model is worse than                                               |

|                            |                                                                                                                                                                                                                                                                        |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            | a one parameter constant model, and can be higher for the smaller of two nested models! The proportion null deviance explained is probably more appropriate for non-normal errors. Note that <code>r.sq</code> does not include any offset in the one parameter model. |
| <code>dev.expl</code>      | The proportion of the null deviance explained by the model. The null deviance is computed taking account of any offset, so <code>dev.expl</code> can be substantially lower than <code>r.sq</code> when an offset is present.                                          |
| <code>edf</code>           | array of estimated degrees of freedom for the model terms.                                                                                                                                                                                                             |
| <code>residual.df</code>   | estimated residual degrees of freedom.                                                                                                                                                                                                                                 |
| <code>n</code>             | number of data.                                                                                                                                                                                                                                                        |
| <code>np</code>            | number of model coefficients (regression coefficients, not smoothing parameters or other parameters of likelihood).                                                                                                                                                    |
| <code>rank</code>          | apparent model rank.                                                                                                                                                                                                                                                   |
| <code>method</code>        | The smoothing selection criterion used.                                                                                                                                                                                                                                |
| <code>sp.criterion</code>  | The minimized value of the smoothness selection criterion. Note that for ML and REML methods, what is reported is the negative log marginal likelihood or negative log restricted likelihood.                                                                          |
| <code>scale</code>         | estimated (or given) scale parameter.                                                                                                                                                                                                                                  |
| <code>family</code>        | the family used.                                                                                                                                                                                                                                                       |
| <code>formula</code>       | the original GAM formula.                                                                                                                                                                                                                                              |
| <code>dispersion</code>    | the scale parameter.                                                                                                                                                                                                                                                   |
| <code>pTerms.df</code>     | the degrees of freedom associated with each parametric term (excluding the constant).                                                                                                                                                                                  |
| <code>pTerms.chi.sq</code> | a Wald statistic for testing the null hypothesis that the each parametric term is zero.                                                                                                                                                                                |
| <code>pTerms.pv</code>     | p-values associated with the tests that each term is zero. For penalized fits these are approximate. The reference distribution is an appropriate chi-squared when the scale parameter is known, and is based on an F when it is not.                                  |
| <code>cov.unscaled</code>  | The estimated covariance matrix of the parameters (or estimators if <code>freq=TRUE</code> ), divided by scale parameter.                                                                                                                                              |
| <code>cov.scaled</code>    | The estimated covariance matrix of the parameters (estimators if <code>freq=TRUE</code> ).                                                                                                                                                                             |
| <code>p.table</code>       | significance table for parameters                                                                                                                                                                                                                                      |
| <code>s.table</code>       | significance table for smooths                                                                                                                                                                                                                                         |
| <code>p.Terms</code>       | significance table for parametric model terms                                                                                                                                                                                                                          |

**WARNING**

The p-values are approximate and neglect smoothing parameter uncertainty. They are likely to be somewhat too low when smoothing parameter estimates are highly uncertain: do read the details section. If the exact values matter, read Wood (2013a or b).

P-values for terms penalized via ‘paraPen’ are unlikely to be correct.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org> with substantial improvements by Henric Nilsson.

 data=dat,method="REML")
summary(bg)
```

t2

*Define alternative tensor product smooths in GAM formulae*

## Description

Alternative to [te](#) for defining tensor product smooths in a [gam](#) formula. Results in a construction in which the penalties are non-overlapping multiples of identity matrices (with some rows and columns zeroed). The construction, which is due to Fabian Scheipl (mgcv implementation, 2010), is analogous to Smoothing Spline ANOVA (Gu, 2002), but using low rank penalized regression spline marginals. The main advantage of this construction is that it is useable with `gamm4` from package `gamm4`.

## Usage

```
t2(..., k=NA,bs="cr",m=NA,d=NA,by=NA,xt=NULL,
 id=NULL,sp=NULL,full=FALSE,ord=NULL,pc=NULL)
```

## Arguments

- |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ... | a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. <code>t2(log(x), z)</code> is fine, but <code>t2(I(x/sd(x)), z)</code> is not (see <a href="#">predict.gam</a> ).                                                                                                                                                                                                                                        |
| k   | the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$ . If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See <a href="#">choose.k</a> for further information.                                                                                                                                                                |
| bs  | array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See <a href="#">smooth.terms</a> for details and full list. User defined bases can also be used here (see <a href="#">smooth.construct</a> for an example). If only one basis code is given then this is used for all bases. |
| m   | The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different <i>m</i> for each margin. For marginals that take vector <i>m</i> (e.g. <a href="#">p.spline</a> and <a href="#">Duchon.spline</a> ), then a list can be supplied, with a vector element for each margin. NA autointializes. <i>m</i> is ignored by some bases (e.g. "cr").                                                      |

|      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d    | array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set <code>d=c(2,1)</code> . Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.                                                                                                                                                                                                                                                |
| by   | a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). In the factor case causes a replicate of the smooth to be produced for each factor level. See <a href="#">gam.models</a> for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see <a href="#">gam.models</a> and <a href="#">linear.functional.terms</a> for details). |
| xt   | Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.                                                                                                                                                                                                                                                                                                                                                                                                          |
| id   | A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).                                                                                                                                                                                                                                 |
| sp   | any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in <code>sp</code> argument to <a href="#">gam</a> . Ignored by <a href="#">gamm</a> .                                                                                                                                                                                                       |
| full | If TRUE then there is a separate penalty for each combination of null space column and range space. This gives strict invariance. If FALSE each combination of null space and range space generates one penalty, but the columns of each null space basis are treated as one group. The latter is more parsimonious, but does mean that invariance is only achieved by an arbitrary rescaling of null space basis vectors.                                                                                                                                                |
| ord  | an array giving the orders of terms to retain. Here order means number of marginal range spaces used in the construction of the component. NULL to retain everything.                                                                                                                                                                                                                                                                                                                                                                                                     |
| pc   | If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See <a href="#">identifiability</a> .                                                                                                                                                                                                                                                                                                                                 |

## Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices. These are reparameterized so that the penalty is zero everywhere, except for some elements on the leading diagonal, which all have the same non-zero value. This reparameterization results in an unpenalized and a penalized subset of parameters, for each marginal basis (see e.g. appendix of Wood, 2004, for details).

The re-parameterized marginal bases are then combined to produce a basis for a single function of all the covariates (dimension given by the product of the dimensions of the marginal bases). In this set up there are multiple penalty matrices — all zero, but for a mixture of a constant and zeros on the leading diagonal. No two penalties have a non-zero entry in the same place.

Essentially the basis for the tensor product can be thought of as being constructed from a set of products of the penalized (range) or unpenalized (null) space bases of the marginal smooths (see

Gu, 2002, section 2.4). To construct one of the set, choose either the null space or the range space from each marginal, and from these bases construct a product basis. The result is subject to a ridge penalty (unless it happens to be a product entirely of marginal null spaces). The whole basis for the smooth is constructed from all the different product bases that can be constructed in this way. The separately penalized components of the smooth basis each have an interpretation in terms of the ANOVA - decomposition of the term. See [pen.edf](#) for some further information.

Note that there are two ways to construct the product. When `full=FALSE` then the null space bases are treated as a whole in each product, but when `full=TRUE` each null space column is treated as a separate null space. The latter results in more penalties, but is the strict analog of the SS-ANOVA approach.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

Note also that GAMs constructed from lower rank tensor product smooths are nested within GAMs constructed from higher rank tensor product smooths if the same marginal bases are used in both cases (the marginal smooths themselves are just special cases of tensor product smooths.)

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

## Value

A class `t2.smooth.spec` object defining a tensor product smooth to be turned into a basis and penalties by the `smooth.construct.tensor.smooth.spec` function.

The returned object contains the following items:

|                     |                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>margin</code> | A list of <code>smooth.spec</code> objects of the type returned by <a href="#">s</a> , defining the basis from which the tensor product smooth is constructed.    |
| <code>term</code>   | An array of text strings giving the names of the covariates that the term is a function of.                                                                       |
| <code>by</code>     | is the name of any by variable as text ("NA" for none).                                                                                                           |
| <code>fx</code>     | logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise. |
| <code>label</code>  | A suitable text label for this smooth term.                                                                                                                       |
| <code>dim</code>    | The dimension of the smoother - i.e. the number of covariates that it is a function of.                                                                           |
| <code>mp</code>     | TRUE is multiple penalties are to be used (default).                                                                                                              |
| <code>np</code>     | TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).                                                                               |
| <code>id</code>     | the <code>id</code> argument supplied to <code>te</code> .                                                                                                        |
| <code>sp</code>     | the <code>sp</code> argument supplied to <code>te</code> .                                                                                                        |

te

*Define tensor product smooths or tensor product interactions in GAM formulae*

## Description

Functions used for the definition of tensor product smooths and interactions within gam model formulae. `te` produces a full tensor product smooth, while `ti` produces a tensor product interaction, appropriate when the main effects (and any lower interactions) are also present.

The functions do not evaluate the smooth - they exist purely to help set up a model using tensor product based smooths. Designed to construct tensor products from any marginal smooths with a basis-penalty representation (with the restriction that each marginal smooth must have only one penalty).

## Usage

```
te(..., k=NA,bs="cr",m=NA,d=NA,by=NA,fx=FALSE,
 np=TRUE,xt=NULL,id=NULL,sp=NULL,pc=NULL)
ti(..., k=NA,bs="cr",m=NA,d=NA,by=NA,fx=FALSE,
 np=TRUE,xt=NULL,id=NULL,sp=NULL,mc=NULL,pc=NULL)
```

## Arguments

... a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. `te(log(x),z)` is fine, but `te(I(x/sd(x)),z)` is not (see [predict.gam](#)).

|    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| k  | the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$ . If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See <a href="#">choose.k</a> for further information.                                                                                                                                                                                                         |
| bs | array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See <a href="#">smooth.terms</a> for details and full list. User defined bases can also be used here (see <a href="#">smooth.construct</a> for an example). If only one basis code is given then this is used for all bases.                                          |
| m  | The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different m for each margin. For marginals that take vector m (e.g. <a href="#">p.spline</a> and <a href="#">Duchon.spline</a> ), then a list can be supplied, with a vector element for each margin. NA autoinitializes. m is ignored by some bases (e.g. "cr").                                                                                                                   |
| d  | array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set $d=c(2,1)$ . Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.                                                                                                                                                                                                                                                           |
| by | a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a 'varying coefficient model' results). In the factor case causes a replicate of the smooth to be produced for each factor level. See <a href="#">gam.models</a> for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see <a href="#">gam.models</a> and <a href="#">linear.functional.terms</a> for details). |
| fx | indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| np | TRUE to use the 'normal parameterization' for a tensor product smooth. This represents any 1-d marginal smooths via parameters that are function values at 'knots', spread evenly through the data. The parameterization makes the penalties easily interpretable, however it can reduce numerical stability in some cases.                                                                                                                                                                                                                                               |
| xt | Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.                                                                                                                                                                                                                                                                                                                                                                                                          |
| id | A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).                                                                                                                                                                                                                                 |
| sp | any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to <a href="#">gam</a> . Ignored by <a href="#">gamm</a> .                                                                                                                                                                                                                    |
| mc | For <a href="#">ti</a> smooths you can specify which marginals should have centering constraints applied, by supplying 0/1 or FALSE/TRUE values for each marginal in this vector. By default all marginals are constrained, which is what is appropriate for, e.g., functional ANOVA models. Note that 'ti' only applies constraints                                                                                                                                                                                                                                      |

to the marginals, so if you turn off all marginal constraints the term will have no identifiability constraints. Only use this if you really understand how marginal constraints work.

**pc** If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied as a number. See [identifiability](#). Can also be supplied as a list of lists to specify general linear constraints as described in [scasm](#) - ignored by other modelling routines.

## Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices, and these are then combined in the manner described in [tensor.prod.model.matrix](#) and [tensor.prod.penalties](#), to produce a single model matrix for the smooth, but multiple penalties (one for each marginal basis). The basis dimension of the whole smooth is the product of the basis dimensions of the marginal smooths.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

It is sometimes useful to investigate smooth models with a main-effects + interactions structure, for example

$$f_1(x) + f_2(z) + f_3(x, z)$$

This functional ANOVA decomposition is supported by **ti** terms, which produce tensor product interactions from which the main effects have been excluded, under the assumption that they will be included separately. For example the `~ ti(x) + ti(z) + ti(x, z)` would produce the above main effects + interaction structure. This is much better than attempting the same thing with **te** terms representing the interactions (although **mgcv** does not forbid it). Technically **ti** terms are very simple: they simply construct tensor product bases from marginal smooths to which identifiability constraints (usually sum-to-zero) have already been applied: correct nesting is then automatic (as with all interactions in a GLM framework). See Wood (2017, section 5.6.3).

The ‘normal parameterization’ (`np=TRUE`) re-parameterizes the marginal smooths of a tensor product smooth so that the parameters are function values at a set of points spread evenly through the range of values of the covariate of the smooth. This means that the penalty of the tensor product associated with any particular covariate direction can be interpreted as the penalty of the appropriate marginal smooth applied in that direction and averaged over the smooth. Currently this is only done for marginals of a single variable. This parameterization can reduce numerical stability when used with marginal smooths other than “cc”, “cr” and “cs”: if this causes problems, set `np=FALSE`.

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

## Value

A class `tensor.smooth.spec` object defining a tensor product smooth to be turned into a basis and penalties by the `smooth.construct.tensor.smooth.spec` function.

The returned object contains the following items:

**margin** A list of `smooth.spec` objects of the type returned by [s](#), defining the basis from which the tensor product smooth is constructed.

|       |                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| term  | An array of text strings giving the names of the covariates that the term is a function of.                                                                       |
| by    | is the name of any by variable as text ("NA" for none).                                                                                                           |
| fx    | logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise. |
| label | A suitable text label for this smooth term.                                                                                                                       |
| dim   | The dimension of the smoother - i.e. the number of covariates that it is a function of.                                                                           |
| mp    | TRUE is multiple penalties are to be used (default).                                                                                                              |
| np    | TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).                                                                               |
| id    | the id argument supplied to te.                                                                                                                                   |
| sp    | the sp argument supplied to te.                                                                                                                                   |
| inter | TRUE if the term was generated by ti, FALSE otherwise.                                                                                                            |
| mc    | the argument mc supplied to ti.                                                                                                                                   |

tensor.prod.model.matrix

*Row Kronecker product/ tensor product smooth construction*

---

## Description

Produce model matrices or penalty matrices for a tensor product smooth from the model matrices or penalty matrices for the marginal bases of the smooth (marginals and results can be sparse). The model matrix construction uses row Kronecker products.

## Usage

```

tensor.prod.model.matrix(X)
tensor.prod.penalties(S)
a%.%b

```

## Arguments

|   |                                                                                                                                        |
|---|----------------------------------------------------------------------------------------------------------------------------------------|
| X | a list of model matrices for the marginal bases of a smooth. Items can be class "matrix" or "dgCMatrix", but not a mixture of the two. |
| S | a list of penalties for the marginal bases of a smooth.                                                                                |
| a | a matrix with the same number of rows as A.                                                                                            |
| b | a matrix with the same number of rows as B.                                                                                            |

## Details

If  $X[[1]]$ ,  $X[[2]]$  ...  $X[[m]]$  are the model matrices of the marginal bases of a tensor product smooth then the  $i$ th row of the model matrix for the whole tensor product smooth is given by  $X[[1]][i,] \%x\% X[[2]][i,] \%x\% \dots X[[m]][i,]$ , where  $\%x\%$  is the Kronecker product. Of course the routine operates column-wise, not row-wise!

$A\%.\%B$  is the operator form of this ‘row Kronecker product’.

If  $S[[1]]$ ,  $S[[2]]$  ...  $S[[m]]$  are the penalty matrices for the marginal bases, and  $I[[1]]$ ,  $I[[2]]$  ...  $I[[m]]$  are corresponding identity matrices, each of the same dimension as its corresponding penalty, then the tensor product smooth has  $m$  associate penalties of the form:

$S[[1]] \%x\% I[[2]] \%x\% \dots I[[m]]$ ,

$I[[1]] \%x\% S[[2]] \%x\% \dots I[[m]]$

...

$I[[1]] \%x\% I[[2]] \%x\% \dots S[[m]]$ .

Of course it’s important that the model matrices and penalty matrices are presented in the same order when constructing tensor product smooths.

## Value

Either a single model matrix for a tensor product smooth (of the same class as the marginals), or a list of penalty terms for a tensor product smooth.

|-------------------|------------------------------------------------------------------------------------|
| totalPenaltySpace | <i>Obtaining (orthogonal) basis for null space and range of the penalty matrix</i> |
|-------------------|------------------------------------------------------------------------------------|

---

**Description**

INTERNAL function to obtain (orthogonal) basis for the null space and range space of the penalty, and obtain actual null space dimension components are roughly rescaled to avoid any dominating.

**Usage**

```
totalPenaltySpace(S, H, off, p)
```

**Arguments**

|     |                                                                                                  |
|-----|--------------------------------------------------------------------------------------------------|
| S   | a list of penalty matrices, in packed form.                                                      |
| H   | the coefficient matrix of an user supplied fixed quadratic penalty on the parameters of the GAM. |
| off | a vector where the i-th element is the offset for the i-th matrix.                               |
| p   | total number of parameters.                                                                      |

**Value**

A list of matrix square roots such that  $S[[i]] = B[[i]] \%*\% t(B[[i]])$ .

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.

---

|         |                                                        |
|---------|--------------------------------------------------------|
| trichol | <i>Choleski decomposition of a tri-diagonal matrix</i> |
|---------|--------------------------------------------------------|

---

**Description**

Computes Choleski decomposition of a (symmetric positive definite) tri-diagonal matrix stored as a leading diagonal and sub/super diagonal.

**Usage**

```
trichol(ld, sd)
```

**Arguments**

|    |                              |
|----|------------------------------|
| ld | leading diagonal of matrix   |
| sd | sub-super diagonal of matrix |

**Details**

Calls `dpttrf` from LAPACK. The point of this is that it has  $O(n)$  computational cost, rather than the  $O(n^3)$  required by dense matrix methods.

**Value**

A list with elements `ld` and `sd`. `ld` is the leading diagonal and `sd` is the super diagonal of bidiagonal matrix  $\mathbf{B}$  where  $\mathbf{B}^T \mathbf{B} = \mathbf{T}$  and  $\mathbf{T}$  is the original tridiagonal matrix.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

```

---

trind.generator

*Generates index arrays for upper triangular storage*

---

**Description**

Generates index arrays for upper triangular storage up to order four. Useful when working with higher order derivatives, which generate symmetric arrays. Mainly intended for internal use.

**Usage**

```
trind.generator(K = 2, ifunc=FALSE, reverse= !ifunc)
```

**Arguments**

|                      |                                                                                    |
|----------------------|------------------------------------------------------------------------------------|
| <code>K</code>       | positive integer determining the size of the array.                                |
| <code>ifunc</code>   | if TRUE index functions are returned in place of index arrays.                     |
| <code>reverse</code> | should the reverse indices be computed? Probably not if <code>ifunc==TRUE</code> . |

## Details

Suppose that  $m=1$  and you fill an array using code like `for(i in 1:K) for(j in i:K) for(k in j:K) for(l in k:K) {a[,m] <- something; m <- m+1 }` and do this because actually the same "something" would be stored for any permutation of the indices  $i,j,k,l$ . Clearly in storage we have the restriction  $l \geq k \geq j \geq i$ , but for access we want no restriction on the indices. `i4[i,j,k,l]` produces the appropriate  $m$  for unrestricted indices. `i3` and `i2` do the same for 3d and 2d arrays. If `ifunc==TRUE` then `i2`, `i3` and `i4` are functions, so `i4(i,j,k,l)` returns appropriate  $m$ . For high  $K$  the function versions save storage, but are slower.

If computed, the reverse indices pick out the unique elements of a symmetric array stored redundantly. The indices refer to the location of the elements when the redundant array is accessed as its underlying vector. For example the reverse indices for a 3 by 3 symmetric matrix are 1,2,3,5,6,9.

## Value

A list where the entries `i1` to `i4` are arrays in up to four dimensions, containing  $K$  indexes along each dimension. If `ifunc==TRUE` index functions are returned in place of index arrays. If `reverse==TRUE` reverse indices `i1r` to `i4r` are returned (always as arrays).

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>.

## Examples

```
library(mgcv)
A <- trind.generator(3,reverse=TRUE)

All permutations of c(1, 2, 3) point to the same index (5)
A$i3[1, 2, 3]
A$i3[2, 1, 3]
A$i3[2, 3, 1]
A$i3[3, 1, 2]
A$i3[1, 3, 2]

use reverse indices to pick out unique elements
just for illustration...
A$i2;A$i2[A$i2r]
A$i3[A$i3r]

same again using function indices...
A <- trind.generator(3,ifunc=TRUE)
A$i3(1, 2, 3)
A$i3(2, 1, 3)
A$i3(2, 3, 1)
A$i3(3, 1, 2)
A$i3(1, 3, 2)
```

Tweedie

*GAM Tweedie families***Description**

Tweedie families, designed for use with [gam](#) from the [mgcv](#) library. Restricted to variance function powers between 1 and 2. A useful alternative to [quasi](#) when a full likelihood is desirable. Tweedie is for use with fixed  $p$ . `tw` is for use when  $p$  is to be estimated during fitting. For fixed  $p$  between 1 and 2 the Tweedie is an exponential family distribution with variance given by the mean to the power  $p$ .

`tw` is only useable with [gam](#) and [bam](#) but not `gamm`. Tweedie works with all three.

**Usage**

```
Tweedie(p=1, link = power(0))
tw(theta = NULL, link = "log", a=1.01, b=1.99)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>p</code>     | the variance of an observation is proportional to its mean to the power $p$ . $p$ must be greater than 1 and less than or equal to 2. 1 would be Poisson, 2 is gamma.                                                                                                        |
| <code>link</code>  | The link function: one of "log", "identity", "inverse", "sqrt", or a <a href="#">power</a> link (Tweedie only).                                                                                                                                                              |
| <code>theta</code> | Related to the Tweedie power parameter by $p = (a + b \exp(\theta)) / (1 + \exp(\theta))$ . If this is supplied as a positive value then it is taken as the fixed value for $p$ . If it is a negative values then its absolute value is taken as the initial value for $p$ . |
| <code>a</code>     | lower limit on $p$ for optimization.                                                                                                                                                                                                                                         |
| <code>b</code>     | upper limit on $p$ for optimization.                                                                                                                                                                                                                                         |

**Details**

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution. The  $p=1$  case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For  $1 < p < 2$  the distribution is supported on the positive reals with a point mass at zero.  $p=2$  is a gamma distribution. As  $p$  gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at  $p=1$ , and is therefore highly multimodal. See [ldTweedie](#) for more on this behaviour.

Tweedie is based partly on the [poisson](#) family, and partly on `tweedie` from the `statmod` package. It includes extra components to work with all `mgcv` GAM fitting methods as well as an `aic` function.

The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t.  $p$  and the scale parameter. Without restricting  $p$  to (1,2) the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over [quasi](#). If you need this case then the `tweedie` package is the place to start.

**Value**

For `Tweedie`, an object inheriting from class `family`, with additional elements

|                    |                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>dvar</code>  | the function giving the first derivative of the variance function w.r.t. $\mu$ .                                                     |
| <code>d2var</code> | the function giving the second derivative of the variance function w.r.t. $\mu$ .                                                    |
| <code>ls</code>    | A function returning a 3 element array: the saturated log likelihood followed by its first 2 derivatives w.r.t. the scale parameter. |

For `tw`, an object of class `extended.family`.

**WARNINGS**

As  $p$  and the scale parameter tend to 1 the Tweedie distribution tends towards a Poisson, however it remains continuously supported, meaning that the corresponding log likelihood does not converge on the Poisson log likelihood. For example, AIC can be radically different for Poisson and Tweedie models for which the fit is almost identical.

*Tweedie location scale family*

## Description

Tweedie family in which the mean, scale and power parameters can all depend on smooth linear predictors. Restricted to estimation via the extended Fellner Schall method of Wood and Fasiolo (2017). Only usable with [gam](#). Tweedie distributions are exponential family with variance given by  $\phi\mu^p$  where  $\phi$  is a scale parameter,  $p$  a parameter (here between 1 and 2) and  $\mu$  is the mean.

## Usage

```
twlss(link=list("log","identity","identity"),a=1.01,b=1.99)
```

## Arguments

|      |                                                               |
|------|---------------------------------------------------------------|
| link | The link function list: currently no choice.                  |
| a    | lower limit on the power parameter relating variance to mean. |
| b    | upper limit on power parameter.                               |

## Details

The first linear predictor defines the mean parameter  $\mu$  (default link log). The Tweedie variance is given by  $\phi\mu^p$ . The second linear predictor defines the log scale parameter  $\rho = \log(\phi)$  (no link choice). The third linear predictor,  $\theta$ , defines  $p = \{a + b \exp(\theta)\} / \{1 + \exp(\theta)\}$  (again with no choice of link).

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution. The  $p=1$  case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For  $1 < p < 2$  the distribution is supported on the positive reals with a point mass at zero.  $p=2$  is a gamma distribution. As  $p$  gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at  $p=1$ , and is therefore highly multimodal. See [ldTweedie](#) for more on this behaviour.

The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t.  $p$  and the scale parameter. Without restricting  $p$  to (1,2) the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over [quasi](#). If you need this case then the [tweedie](#) package is the place to start.

**Value**

An object inheriting from class `general.family`.

uniquecombs

*find the unique rows in a matrix***Description**

This routine returns a matrix or data frame containing all the unique rows of the matrix or data frame supplied as its argument. That is, all the duplicate rows are stripped out. Note that the ordering of the rows on exit need not be the same as on entry. It also returns an index attribute for relating the result back to the original matrix.

**Usage**

```
uniquecombs(x,ordered=FALSE)
```

**Arguments**

|         |                                                                                                     |
|---------|-----------------------------------------------------------------------------------------------------|
| x       | is an R matrix (numeric), or data frame.                                                            |
| ordered | set to TRUE to have the rows of the returned object in the same order regardless of input ordering. |

**Details**

Models with more parameters than unique combinations of covariates are not identifiable. This routine provides a means of evaluating the number of unique combinations of covariates in a model.

When x has only one column then the routine uses `unique` and `match` to get the index. When there are multiple columns then it uses `paste0` to produce labels for each row, which should be unique if the row is unique. Then `unique` and `match` can be used as in the single column case. Obviously the pasting is inefficient, but still quicker for large n than the C based code that used to be called by this routine, which had  $O(n \log(n))$  cost. In principle a hash table based solution in C would be only  $O(n)$  and much quicker in the multicolumn case.

`unique` and `duplicated`, can be used in place of this, if the full index is not needed. Relative performance is variable.

If x is not a matrix or data frame on entry then an attempt is made to coerce it to a data frame.

**Value**

A matrix or data frame consisting of the unique rows of x (in arbitrary order).

The matrix or data frame has an "index" attribute. `index[i]` gives the row of the returned matrix that contains row i of the original matrix.

**WARNINGS**

If a dataframe contains variables of a type other than numeric, logical, factor or character, which either have no `as.character` method, or whose `as.character` method is a many to one mapping, then the routine is likely to fail.

If the character representation of a dataframe variable (other than of class factor or character) contains \* then in principle the method could fail (but with a warning).

[unique](#), [duplicated](#), [match](#).

**Examples**

```
require(mgcv)

matrix example...
X <- matrix(c(1,2,3,1,2,3,4,5,6,1,3,2,4,5,6,1,1,1),6,3,byrow=TRUE)
print(X)
Xu <- uniquecombs(X);Xu
ind <- attr(Xu,"index")
find the value for row 3 of the original from Xu
Xu[ind[3,],];X[3,]

same with fixed output ordering
Xu <- uniquecombs(X,TRUE);Xu
ind <- attr(Xu,"index")
find the value for row 3 of the original from Xu
Xu[ind[3,],];X[3,]

data frame example...
df <- data.frame(f=factor(c("er",3,"b","er",3,3,1,2,"b")),
 x=c(.5,1,1.4,.5,1,.6,4,3,1.7),
 bb = c(rep(TRUE,5),rep(FALSE,4)),
 fred = c("foo","a","b","foo","a","vf","er","r","g"),
 stringsAsFactors=FALSE)
uniquecombs(df)
```

---

vcov.gam

---

*Extract parameter (estimator) covariance matrix from GAM fit*

---

**Description**

Extracts the Bayesian posterior covariance matrix of the parameters or frequentist covariance matrix of the parameter estimators from a fitted gam object.

**Usage**

```
S3 method for class 'gam'
vcov(object, sandwich=FALSE, freq = FALSE, dispersion = NULL, unconditional=FALSE, ...)
```

**Arguments**

|          |                                                                                            |
|----------|--------------------------------------------------------------------------------------------|
| object   | fitted model object of class gam as produced by gam().                                     |
| sandwich | compute sandwich estimate of covariance matrix. Currently expensive for discrete bam fits. |

|               |                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| freq          | TRUE to return the frequentist covariance matrix of the parameter estimators, FALSE to return the Bayesian posterior covariance matrix of the parameters. The latter option includes the expected squared bias according to the Bayesian smoothing prior. |
| dispersion    | a value for the dispersion parameter: not normally used.                                                                                                                                                                                                  |
| unconditional | if TRUE (and freq==FALSE) then the Bayesian smoothing parameter uncertainty corrected covariance matrix is returned, if available.                                                                                                                        |
| ...           | other arguments, currently ignored.                                                                                                                                                                                                                       |

### Details

Basically, just extracts `object$Ve`, `object$Vp` or `object$Vc` (if available) from a [gamObject](#), unless `sandwich==TRUE` in which case the sandwich estimate is computed (with or without the squared bias component).

### Value

A matrix corresponding to the estimated frequentist covariance matrix of the model parameter estimators/coefficients, or the estimated posterior covariance matrix of the parameters, depending on the argument `freq`.

### Examples

```
require(mgcv)
n <- 100
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=10),knots=list(x=seq(0,1,length=10)))
diag(vcov(mod))
```

---

vis.gam

---

*Visualization of GAM objects*

---

### Description

Produces perspective or contour plot views of gam model predictions, fixing all but the values in view to the values supplied in `cond`.

**Usage**

```
vis.gam(x, view=NULL, cond=list(), n.grid=30, too.far=0, col=NA,
 color="heat", contour.col=NULL, se=-1, type="link",
 plot.type="persp", zlim=NULL, nCol=50, lp=1, ...)
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | a gam object, produced by gam()                                                                                                                                                                                                                                                                                                                                               |
| view        | an array containing the names of the two main effect terms to be displayed on the x and y dimensions of the plot. If omitted the first two suitable terms will be used. Note that variables coerced to factors in the model formula won't work as view variables, and vis.gam can not detect that this has happened when setting defaults.                                    |
| cond        | a named list of the values to use for the other predictor terms (not in view). Variables omitted from this list will have the closest observed value to the median for continuous variables, or the most commonly occurring level for factors. Parametric matrix variables have all the entries in each column set to the observed column entry closest to the column median. |
| n.grid      | The number of grid nodes in each direction used for calculating the plotted surface.                                                                                                                                                                                                                                                                                          |
| too.far     | plot grid nodes that are too far from the points defined by the variables given in view can be excluded from the plot. too.far determines what is too far. The grid is scaled into the unit square along with the view variables and then grid nodes more than too.far from the predictor variables are excluded.                                                             |
| col         | The colours for the facets of the plot. If this is NA then if se>0 the facets are transparent, otherwise the colour scheme specified in color is used. If col is not NA then it is used as the facet colour.                                                                                                                                                                  |
| color       | the colour scheme to use for plots when se<=0. One of "topo", "heat", "cm", "terrain", "gray" or "bw". Schemes "gray" and "bw" also modify the colors used when se>0.                                                                                                                                                                                                         |
| contour.col | sets the colour of contours when using plot.type="contour". Default scheme used if NULL.                                                                                                                                                                                                                                                                                      |
| se          | if less than or equal to zero then only the predicted surface is plotted, but if greater than zero, then 3 surfaces are plotted, one at the predicted values minus se standard errors, one at the predicted values and one at the predicted values plus se standard errors.                                                                                                   |
| type        | "link" to plot on linear predictor scale and "response" to plot on the response scale.                                                                                                                                                                                                                                                                                        |
| plot.type   | one of "contour" or "persp".                                                                                                                                                                                                                                                                                                                                                  |
| zlim        | a two item array giving the lower and upper limits for the z-axis scale. NULL to choose automatically.                                                                                                                                                                                                                                                                        |
| nCol        | The number of colors to use in color schemes.                                                                                                                                                                                                                                                                                                                                 |
| lp          | selects the linear predictor for models with more than one.                                                                                                                                                                                                                                                                                                                   |
| ...         | other options to pass on to <a href="#">persp</a> , <a href="#">image</a> or <a href="#">contour</a> . In particular ticktype="detailed" will add proper axes labelling to the plots.                                                                                                                                                                                         |

## Details

The x and y limits are determined by the ranges of the terms named in view. If  $se \leq 0$  then a single (height colour coded, by default) surface is produced, otherwise three (by default see-through) meshes are produced at mean and  $\pm se$  standard errors. Parts of the x-y plane too far from data can be excluded by setting `too.far`

All options to the underlying graphics functions can be reset by passing them as extra arguments ...: such supplied values will always over-ride the default values used by `vis.gam`.

## Value

Simply produces a plot.

## WARNINGS

The routine can not detect that a variable has been coerced to factor within a model formula, and will therefore fail if such a variable is used as a view variable. When setting default view variables it can not detect this situation either, which can cause failures if the coerced variables are the first, otherwise suitable, variables encountered.

## Author(s)

Simon Wood <simon.wood@r-project.org>

Based on an original idea and design by Mike Lonergan.

## Examples

```
library(mgcv)
set.seed(0)
n<-200;sig2<-4
x0 <- runif(n, 0, 1);x1 <- runif(n, 0, 1)
x2 <- runif(n, 0, 1)
y<-x0^2+x1*x2 +runif(n,-0.3,0.3)
g<-gam(y~s(x0,x1,x2))
old.par<-par(mfrow=c(2,2))
display the prediction surface in x0, x1
vis.gam(g,ticktype="detailed",color="heat",theta=-35)
vis.gam(g,se=2,theta=-35) # with twice standard error surfaces
vis.gam(g, view=c("x1","x2"),cond=list(x0=0.75)) # different view
vis.gam(g, view=c("x1","x2"),cond=list(x0=0.75),theta=210,phi=40,
 too.far=.07)
..... areas where there is no data are not plotted

contour examples...
vis.gam(g, view=c("x1","x2"),plot.type="contour",color="heat")
vis.gam(g, view=c("x1","x2"),plot.type="contour",color="terrain")
vis.gam(g, view=c("x1","x2"),plot.type="contour",color="topo")
vis.gam(g, view=c("x1","x2"),plot.type="contour",color="cm")

par(old.par)
```

```
Examples with factor and "by" variables

fac<-rep(1:4,20)
x<-runif(80)
y<-fac+2*x^2+rnorm(80)*0.1
fac<-factor(fac)
b<-gam(y~fac+s(x))

vis.gam(b,theta=-35,color="heat") # factor example

z<-rnorm(80)*0.4
y<-as.numeric(fac)+3*x^2*z+rnorm(80)*0.1
b<-gam(y~fac+s(x,by=z))

vis.gam(b,theta=-35,color="heat",cond=list(z=1)) # by variable example

vis.gam(b,view=c("z","x"),theta=-135) # plot against by variable
```

XWXd

*Internal functions for discretized model matrix handling*

## Description

Routines for computing with discretized model matrices as described in Wood et al. (2017) and Li and Wood (2019).

## Usage

```
XWXd(X,w,k,ks,ts,dt,v,qc,nthreads=1,drop=NULL,ar.stop=-1,ar.row=-1,ar.w=-1,
 lt=NULL,rt=NULL)
XWyd(X,w,y,k,ks,ts,dt,v,qc,drop=NULL,ar.stop=-1,ar.row=-1,ar.w=-1,lt=NULL)
Xbd(X,beta,k,ks,ts,dt,v,qc,drop=NULL,lt=NULL)
diagXVXd(X,V,k,ks,ts,dt,v,qc,drop=NULL,nthreads=1,lt=NULL,rt=NULL)
ijXVXd(i,j,X,V,k,ks,ts,dt,v,qc,drop=NULL,nthreads=1,lt=NULL,rt=NULL)
```

## Arguments

- |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>X</b>    | A list of the matrices containing the unique rows of model matrices for terms of a full model matrix, or the model matrices of the terms margins. if term subsetting arguments <b>lt</b> and <b>rt</b> are non-NULL then this requires an "lpip" attribute: see details. The elements of <b>X</b> may be sparse matrices of class "dgCMatrix", in which case the list requires attributes "r" and "off" defining reverse indices (see details). |
| <b>w</b>    | An n-vector of weights                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>y</b>    | n-vector of data.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>beta</b> | coefficient vector.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>k</b>    | A matrix whose columns are index n-vectors each selecting the rows of an $X[[i]]$ required to create the full matrix.                                                                                                                                                                                                                                                                                                                           |
| <b>ks</b>   | The <i>i</i> th term has index vectors $ks[i,1]:(ks[i,2]-1)$ . The corresponding full model matrices are summed over.                                                                                                                                                                                                                                                                                                                           |

|          |                                                                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ts       | The element of X at which each model term starts.                                                                                                                                         |
| dt       | How many elements of X contribute to each term.                                                                                                                                           |
| v        | $v[[i]]$ is Householder vector for ith term, if $qc[i]>0$ .                                                                                                                               |
| qc       | if $qc[i]>0$ then term has a constraint.                                                                                                                                                  |
| nthreads | number of threads to use                                                                                                                                                                  |
| drop     | list of columns of model matrix/parameters to drop                                                                                                                                        |
| ar.stop  | Negative to ignore. Otherwise sum rows $(ar.stop[i-1]+1):ar.stop[i]$ of the rows selected by <code>ar.row</code> and weighted by <code>ar.w</code> to get ith row of model matrix to use. |
| ar.row   | extract these rows...                                                                                                                                                                     |
| ar.w     | weight by these weights, and sum up according to <code>ar.stop</code> . Used to implement AR models.                                                                                      |
| lt       | use only columns of X corresponding to these model matrix terms (for left hand X in XWXd). If NULL set to <code>rt</code> .                                                               |
| rt       | as <code>lt</code> for right hand X. If NULL set to <code>lt</code> . If <code>lt</code> and <code>rt</code> are NULL use all columns.                                                    |
| V        | Coefficient covariance matrix.                                                                                                                                                            |
| i        | vector of rows of $XVX^T$ at which to evaluate.                                                                                                                                           |
| j        | vector of corresponding columns.                                                                                                                                                          |

## Details

These functions are really intended to be internal, but are exported so that they can be used in the initialization code of families without problem. They are primarily used by `bam` to implement the methods given in the references. `XWXd` produces  $X^T W X$ , `XWy` produces  $X^T W y$ , `Xbd` produces  $X\beta$  and `diagXVXd` produces the diagonal of  $XVX^T$ , while `ijXVXd` evaluates the scattered  $i, j$  elements indexed in `i` and `j`.

The "lrip" attribute of X is a list of the coefficient indices for each term. Required if subsetting via `lt` and `rt`.

X can be a list of sparse matrices of class "dgCMatrix", in which case reverse indices are needed, mapping stored matrix rows to rows in the full matrix (that is the reverse of `k` which maps full matrix rows to the stored unique matrix rows). `r` is the same dimension as `k` while `off` is a list with as many elements as `k` has columns. `r` and `off` are supplied as attributes to X. For simplicity let `r` and `off` denote a single column and element corresponding to each other: then `r[off[j]:(off[j+1]-1)]` contains the rows of the full matrix corresponding to row `j` of the stored matrix. The reverse indices are essential for efficient computation with sparse matrices. See the example code for how to create them efficiently from the forward index matrix, `k`.

ziP

*GAM zero-inflated (hurdle) Poisson regression family*

## Description

Family for use with [gam](#) or [bam](#), implementing regression for zero inflated Poisson data when the complimentary log log of the zero probability is linearly dependent on the log of the Poisson parameter. Use with great care, noting that simply having many zero response observations is not an indication of zero inflation: the question is whether you have too many zeroes given the specified model.

This sort of model is really only appropriate when none of your covariates help to explain the zeroes in your data. If your covariates predict which observations are likely to have zero mean then adding a zero inflated model on top of this is likely to lead to identifiability problems. Identifiability problems may lead to fit failures, or absurd values for the linear predictor or predicted values.

## Usage

```
ziP(theta = NULL, link = "identity",b=0)
```

## Arguments

|       |                                                                                                                                                                                                                                |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| theta | the 2 parameters controlling the slope and intercept of the linear transform of the mean controlling the zero inflation rate. If supplied then treated as fixed parameters ( $\theta_1$ and $\theta_2$ ), otherwise estimated. |
| link  | The link function: only the "identity" is currently supported.                                                                                                                                                                 |
| b     | a non-negative constant, specifying the minimum dependence of the zero inflation rate on the linear predictor.                                                                                                                 |

## Details

The probability of a zero count is given by  $1 - p$ , whereas the probability of count  $y > 0$  is given by the truncated Poisson probability function  $p\mu^y/((\exp(\mu) - 1)y!)$ . The linear predictor gives  $\log \mu$ , while  $\eta = \log(-\log(1 - p))$  and  $\eta = \theta_1 + \{b + \exp(\theta_2)\} \log \mu$ . The theta parameters are estimated alongside the smoothing parameters. Increasing the b parameter from zero can greatly reduce identifiability problems, particularly when there are very few non-zero data.

The fitted values for this model are the log of the Poisson parameter. Use the predict function with type=="response" to get the predicted expected response. Note that the theta parameters reported in model summaries are  $\theta_1$  and  $b + \exp(\theta_2)$ .

These models should be subject to very careful checking, especially if fitting has not converged. It is quite easy to set up models with identifiability problems, particularly if the data are not really zero inflated, but simply have many zeroes because the mean is very low in some parts of the covariate space. See example for some obvious checks. Take convergence warnings seriously.

**Value**

An object of class `extended.family`.

**WARNINGS**

Zero inflated models are often over-used. Having lots of zeroes in the data does not in itself imply zero inflation. Having too many zeroes \*given the model mean\* may imply zero inflation.

ziplss

---

*Zero inflated (hurdle) Poisson location-scale model family*

---

## Description

The ziplss family implements a zero inflated (hurdle) Poisson model in which one linear predictor controls the probability of presence and the other controls the mean given presence. Useable only with [gam](#), the linear predictors are specified via a list of formulae. Should be used with care: simply having a large number of zeroes is not an indication of zero inflation.

Requires integer count data.

## Usage

```
ziplss(link=list("identity","identity"))
zipll(y,g,eta,deriv=0)
```

## Arguments

|       |                                                                                                                                                                                                           |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| link  | two item list specifying the link - currently only identity links are possible, as parameterization is directly in terms of log of Poisson response and complementary log log of probability of presence. |
| y     | response                                                                                                                                                                                                  |
| g     | gamma vector                                                                                                                                                                                              |
| eta   | eta vector                                                                                                                                                                                                |
| deriv | number of derivatives to compute                                                                                                                                                                          |

## Details

ziplss is used with `gam` to fit 2 stage zero inflated Poisson models. `gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the Poisson parameter on the right hand side. The second is one sided, specifying the linear predictor for the probability of presence on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the log of the Poisson parameter, and the second column is the complementary log log of probability of presence.. Predictions using `predict.gam` will also produce 2 column matrices for type "link" and "response".

The null deviance computed for this model assumes that a single probability of presence and a single Poisson parameter are estimated.

For data with large areas of covariate space over which the response is zero it may be advisable to use low order penalties to avoid problems. For 1D smooths uses e.g. `s(x,m=1)` and for isotropic smooths use `Duchon.splines` in place of thin plate terms with order 1 penalties, e.g `s(x,z,m=c(1,.5))` — such smooths penalize towards constants, thereby avoiding extreme estimates when the data are uninformative.

`zip11` is a function used by `ziplss`, exported only to allow external use of the `ziplss` family. It is not usually called directly.

## Value

For `ziplss` An object inheriting from class `general.family`.

## WARNINGS

Zero inflated models are often over-used. Having many zeroes in the data does not in itself imply zero inflation. Having too many zeroes \*given the model mean\* may imply zero inflation.

# The nlme package

---

ACF

*Autocorrelation Function*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls` and `lme`.

### Usage

```
ACF(object, maxLag, ...)
```

### Arguments

|                     |                                                                                                                                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | any object from which an autocorrelation function can be obtained. Generally an object resulting from a model fit, from which residuals can be extracted. |
| <code>maxLag</code> | maximum lag for which the autocorrelation should be calculated.                                                                                           |
| <code>...</code>    | some methods for this generic require additional arguments.                                                                                               |

### Value

will depend on the method function used; see the appropriate documentation.

ACF.gls

*Autocorrelation Function for gls Residuals***Description**

This method function calculates the empirical autocorrelation function for the residuals from a gls fit. If a grouping variable is specified in form, the autocorrelation values are calculated using pairs of residuals within the same group; otherwise all possible residual pairs are used. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

**Usage**

```
S3 method for class 'gls'
ACF(object, maxLag, resType, form, na.action, ...)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | an object inheriting from class "gls", representing a generalized least squares fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| maxLag    | an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the residuals.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| resType   | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson". |
| form      | an optional one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . The time covariate must be integer valued. When a grouping factor is present in form, the autocorrelations are calculated using residual pairs within the same group. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.                                                                                                               |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes ACF.gls to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                                                          |
| ...       | some methods for this generic require additional arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Value**

a data frame with columns lag and ACF representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class ACF.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

ACF.lme

---

Autocorrelation Function for lme Residuals

---

## Description

This method function calculates the empirical autocorrelation function for the within-group residuals from an lme fit. The autocorrelation values are calculated using pairs of residuals within the innermost group level. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

## Usage

```
S3 method for class 'lme'
ACF(object, maxLag, resType, ...)
```

## Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| maxLag  | an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the within-group residuals.                                                                                                                                                                                                                                                                                                                                                                                                          |
| resType | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson". |
| ...     | some methods for this generic require additional arguments – not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Value**

a data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class `ACF`.

Alfalfa

*Split-Plot Experiment on Varieties of Alfalfa*

---

**Description**

The Alfalfa data frame has 72 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Variety** a factor with levels Cossack, Ladak, and Ranger

**Date** a factor with levels None S1 S20 07

**Block** a factor with levels 1 2 3 4 5 6

**Yield** a numeric vector

## Details

These data are described in Snedecor and Cochran (1980) as an example of a split-plot design. The treatment structure used in the experiment was a  $3 \times 4$  full factorial, with three varieties of alfalfa and four dates of third cutting in 1943. The experimental units were arranged into six blocks, each subdivided into four plots. The varieties of alfalfa (*Cossac*, *Ladak*, and *Ranger*) were assigned randomly to the blocks and the dates of third cutting (*None*, *S1*—September 1, *S20*—September 20, and *O7*—October 7) were randomly assigned to the plots. All four dates were used on each block.

allCoef

---

*Extract Coefficients from a Set of Objects*

---

## Description

The extractor function is applied to each object in `...`, with the result being converted to a vector. A map attribute is included to indicate which pieces of the returned vector correspond to the original objects in dots.

## Usage

```
allCoef(..., extract)
```

## Arguments

|                      |                                                                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>     | objects to which <code>extract</code> will be applied. Generally these will be model components, such as <code>corStruct</code> and <code>varFunc</code> objects. |
| <code>extract</code> | an optional extractor function. Defaults to <code>coef</code> .                                                                                                   |

## Value

a vector with all elements, generally coefficients, obtained by applying `extract` to the objects in `...`

cs1 <- corAR1(0.1)
vf1 <- varPower(0.5)
allCoef(cs1, vf1)
```

anova.gls

*Compare Likelihoods of Fitted Objects***Description**

When only one fitted model object is present, a data frame with the numerator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when Terms and L are NULL), a combination of model terms (when Terms is not NULL), or linear combinations of the model coefficients (when L is not NULL). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If test=TRUE, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic with the associated p-value is included in the returned data frame.

**Usage**

```
S3 method for class 'glS'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
```

**Arguments**

- |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object      | an object inheriting from class "glS", representing a generalized least squares fit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ...         | other optional fitted model objects inheriting from classes "glS", "gnls", "lm", "lme", "lmList", "nlme", "nlsList", or "nls".                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| test        | an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by object and the objects in .... Defaults to TRUE.                                                                                                                                                                                                                                                                                                                                                                                       |
| type        | an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential". |
| adjustSigma | an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.                                                                                                                                                                                                                               |
| Terms       | an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.                                                                                                                           |
| L           | an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will                                                                                                                                                                                                                                    |

be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

**verbose** an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.

### Value

a data frame inheriting from class "anova.lme".

### Note

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

anova.lme

*Compare Likelihoods of Fitted Objects*

## Description

When only one fitted model object is present, a data frame with the numerator degrees of freedom, denominator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when Terms and L are NULL), a combination of model terms (when Terms is not NULL), or linear combinations of the model coefficients (when L is not NULL). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If test=TRUE, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic with the associated p-value is included in the returned data frame.

## Usage

```

S3 method for class 'lme'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
S3 method for class 'anova.lme'
print(x, verbose, ...)

```

## Arguments

|        |                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.                      |
| ...    | other optional fitted model objects inheriting from classes "glms", "gnls", "lm", "lme", "lmList", "nlme", "nlsList", or "nls". |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| test        | an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by object and the objects in . . . Defaults to TRUE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| type        | an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential".                                                                           |
| adjustSigma | an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.                                                                                                                                                                                                                                                                                                         |
| Terms       | an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.                                                                                                                                                                                                     |
| L           | an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL. |
| x           | an object inheriting from class "anova.lme"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| verbose     | an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Value**

a data frame inheriting from class "anova.lme".

**Note**

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

as.matrix.corStruct     *Matrix of a corStruct Object*

---

## Description

This method function extracts the correlation matrix, or list of correlation matrices, associated with object.

**Usage**

```
S3 method for class 'corStruct'
as.matrix(x, ...)
```

**Arguments**

**x** an object inheriting from class "[corStruct](#)", representing a correlation structure.

**...** further arguments passed from other methods.

**Value**

If the correlation structure includes a grouping factor, the returned value will be a list with components given by the correlation matrices for each group. Otherwise, the returned value will be a matrix representing the correlation structure associated with object.

---

asOneFormula

*Combine Formulas of a Set of Objects*

---

**Description**

The names of all variables used in the formulas extracted from the objects defined in `...` are converted into a single linear formula, with the variables names separated by `+`.

**Usage**

```
asOneFormula(..., omit)
```

**Arguments**

`...` objects, or lists of objects, from which a formula can be extracted.

`omit` an optional character vector with the names of variables to be omitted from the returned formula. Defaults to `c(".", "pi")`.

**Value**

a one-sided linear formula with all variables named in the formulas extracted from the objects in `...`, except the ones listed in `omit`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|-------|---------------------------------------|
| Assay | <i>Bioassay on Cell Culture Plate</i> |
|-------|---------------------------------------|

---

### Description

The Assay data frame has 60 rows and 4 columns.

### Format

This data frame contains the following columns:

**Block** an ordered factor with levels 2 < 1 identifying the block where the wells are measured.

**sample** a factor with levels a to f identifying the sample corresponding to the well.

**dilut** a factor with levels 1 to 5 indicating the dilution applied to the well

**logDens** a numeric vector of the log-optical density

### Details

These data, courtesy of Rich Wolfe and David Lansky from Searle, Inc., come from a bioassay run on a 96-well cell culture plate. The assay is performed using a split-block design. The 8 rows on the plate are labeled A–H from top to bottom and the 12 columns on the plate are labeled 1–12 from left to right. Only the central 60 wells of the plate are used for the bioassay (the intersection of rows B–G and columns 2–11). There are two blocks in the design: Block 1 contains columns 2–6 and Block 2 contains columns 7–11. Within each block, six samples are assigned randomly to rows and five (serial) dilutions are assigned randomly to columns. The response variable is the logarithm of the optical density. The cells are treated with a compound that they metabolize to produce the stain. Only live cells can make the stain, so the optical density is a measure of the number of cells that are alive and healthy.

|---------|----------------------------------------|
| asTable | <i>Convert groupedData to a matrix</i> |
|---------|----------------------------------------|

---

### Description

Create a tabular representation of the response in a balanced groupedData object.

### Usage

```
asTable(object)
```

### Arguments

**object** A balanced groupedData object

**Details**

A balanced groupedData object can be represented as a matrix or table of response values corresponding to the values of a primary covariate for each level of a grouping factor. This function creates such a matrix representation of the data in object.

**Value**

A matrix. The data in the matrix are the values of the response. The columns correspond to the distinct values of the primary covariate and are labelled as such. The rows correspond to the distinct levels of the grouping factor and are labelled as such.

```

---

augPred

*Augmented Predictions*

---

**Description**

Predicted values are obtained at the specified values of primary. If object has a grouping structure (i.e. `getGroups(object)` is not `NULL`), predicted values are obtained for each group. If `level` has more than one element, predictions are obtained for each level of the `max(level)` grouping factor. If other covariates besides primary are used in the prediction model, their average (numeric covariates) or most frequent value (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

**Usage**

```
augPred(object, primary, minimum, maximum, length.out, ...)
S3 method for class 'lme'
augPred(object, primary = NULL,
 minimum = min(primary), maximum = max(primary),
 length.out = 51, level = Q, ...)
```

**Arguments**

|            |                                                                                                                                                                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object     | a fitted model object from which predictions can be extracted, using a predict method.                                                                                                                                                               |
| primary    | an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate object (using getCovariate), it will be used as primary. |
| minimum    | an optional lower limit for the primary covariate. Defaults to min(primary).                                                                                                                                                                         |
| maximum    | an optional upper limit for the primary covariate. Defaults to max(primary).                                                                                                                                                                         |
| length.out | an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.                                                                                                                                |
| level      | an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.                    |
| ...        | some methods for the generic may require additional arguments.                                                                                                                                                                                       |

**Value**

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: original for the observed values and predicted (single or no grouping factor) or predict.groupVar (multiple levels of grouping), with groupVar replaced by the actual grouping variable name (fixed is used for population predictions). The returned object inherits from class "augPred".

**Note**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

**Author(s)**

```
fm1 <- lme(Orthodont, random = ~1)
augPred(fm1, length.out = 2, level = c(0,1))
```

---

|                 |                                           |
|-----------------|-------------------------------------------|
| balancedGrouped | Create a groupedData object from a matrix |
|-----------------|-------------------------------------------|

---

## Description

Create a groupedData object from a data matrix. This function can be used only with balanced data. The opposite conversion, from a groupedData object to a matrix, is done with asTable.

## Usage

```
balancedGrouped(form, data, labels=NULL, units=NULL)
```

## Arguments

|        |                                                                                                                                                                                                                                                                                                      |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| form   | A formula of the form $y \sim x \mid g$ giving the name of the response, the primary covariate, and the grouping factor.                                                                                                                                                                             |
| data   | A matrix or data frame containing the values of the response grouped according to the levels of the grouping factor (rows) and the distinct levels of the primary covariate (columns). The dimnames of the matrix are used to construct the levels of the grouping factor and the primary covariate. |
| labels | an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named x and that for the response is named y. Either label can be omitted.                                                                                    |
| units  | an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named x and that for the response is named y. Either units string can be omitted.                                                                   |

## Value

A balanced groupedData object.

bdf

*Language scores*

### Description

The bdf data frame has 2287 rows and 25 columns of language scores from grade 8 pupils in elementary schools in The Netherlands.

### Usage

```
bdf
```

### Format

**schoolNR** a factor denoting the school.

**pupilNR** a factor denoting the pupil.

**IQ.verb** a numeric vector of verbal IQ scores

**IQ.perf** a numeric vector of IQ scores.

**sex** Sex of the student.

**Minority** a factor indicating if the student is a member of a minority group.

**repeatgr** an ordered factor indicating if one or more grades have been repeated.

**aritPRET** a numeric vector

**classNR** a numeric vector

**aritPOST** a numeric vector

**langPRET** a numeric vector

**langPOST** a numeric vector

**ses** a numeric vector of socioeconomic status indicators.

**denomina** a factor indicating if the school is a public school, a Protestant private school, a Catholic private school, or a non-denominational private school.

**schoolSES** a numeric vector

**satiprin** a numeric vector

**natitest** a factor with levels 0 and 1

**meetings** a numeric vector

**currmeet** a numeric vector

**mixedgra** a factor indicating if the class is a mixed-grade class.

**percmينو** a numeric vector

**aritdiff** a numeric vector

**homework** a numeric vector

**classsiz** a numeric vector

**groupsiz** a numeric vector

---

|            |                                                 |
|------------|-------------------------------------------------|
| BodyWeight | <i>Rat weight over time for different diets</i> |
|------------|-------------------------------------------------|

---

## Description

The BodyWeight data frame has 176 rows and 4 columns.

## Format

This data frame contains the following columns:

**weight** a numeric vector giving the body weight of the rat (grams).

**Time** a numeric vector giving the time at which the measurement is made (days).

**Rat** an ordered factor with levels 2 < 3 < 4 < 1 < 8 < 5 < 6 < 7 < 11 < 9 < 10 < 12 < 13 < 15 < 14 < 16 identifying the rat whose weight is measured.

**Diet** a factor with levels 1 to 3 indicating the diet that the rat receives.

## Details

Hand and Crowder (1996) describe data on the body weights of rats measured over 64 days. These data also appear in Table 2.4 of Crowder and Hand (1990). The body weights of the rats (in grams) are measured on day 1 and every seven days thereafter until day 64, with an extra measurement on day 44. The experiment started several weeks before “day 1.” There are three groups of rats, each on a different diet.

Cefamandole

*Pharmacokinetics of Cefamandole***Description**

The Cefamandole data frame has 84 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Subject** a factor giving the subject from which the sample was drawn.

**Time** a numeric vector giving the time at which the sample was drawn (minutes post-injection).

**conc** a numeric vector giving the observed plasma concentration of cefamandole (mcg/ml).

**Details**

Davidian and Giltinan (1995, 1.1, p. 2) describe data obtained during a pilot study to investigate the pharmacokinetics of the drug cefamandole. Plasma concentrations of the drug were measured on six healthy volunteers at 14 time points following an intravenous dose of 15 mg/kg body weight of cefamandole.

**Examples**

```
plot(Cefamandole)
fm1 <- nlsList(SSbiexp, data = Cefamandole)
summary(fm1)
```

Coef

*Assign Values to Coefficients***Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "[pdMat](#)", "[corStruct](#)" and "[varFunc](#)" classes, "[reStruct](#)", and "[modelStruct](#)".

`coefficients<-` is an *alias* for `coef<-`.

**Usage**

```
coef(object, ...) <- value
```

```
coefficients(object, ...) <- value
```

**Arguments**

|        |                                                                                           |
|--------|-------------------------------------------------------------------------------------------|
| object | any object representing a fitted model, or, by default, any object with a coef component. |
| ...    | some methods for this generic function may require additional arguments.                  |
| value  | a value to be assigned to the coefficients associated with object.                        |

**Value**

will depend on the method function; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[coef](#)

---

coef.corStruct

*Coefficients of a corStruct Object*

---

**Description**

This method function extracts the coefficients associated with the correlation structure represented by object.

**Usage**

```
S3 method for class 'corStruct'
coef(object, unconstrained, ...)
S3 replacement method for class 'corStruct'
coef(object, ...) <- value
```

**Arguments**

|               |                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object        | an object inheriting from class " <a href="#">corStruct</a> ", representing a correlation structure.                                                                                                                           |
| unconstrained | a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE. |
| value         | a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of <code>coef{object}</code> and must be given in unconstrained form.                               |
| ...           | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                      |

**Value**

a vector with the coefficients corresponding to object.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

**Author(s)**

José Pinheiro and Douglas Bates

Examples

```
fm1 <- gnlS(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
 weights = varPower())
coef(fm1)
```

---

|          |                                 |
|----------|---------------------------------|
| coef.lme | <i>Extract lme Coefficients</i> |
|----------|---------------------------------|

---

Description

The estimated coefficients at level *i* are obtained by adding together the fixed effects estimates and the corresponding random effects estimates at grouping levels less or equal to *i*. The resulting estimates are returned as a data frame, with rows corresponding to groups and columns to coefficients. Optionally, the returned data frame may be augmented with covariates summarized over groups.

Usage

```
S3 method for class 'lme'
coef(object, augFrame, level, data, which, FUN,
 omitGroupingFactor, subset, ...)
```

Arguments

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object   | an object inheriting from class "lme", representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| augFrame | an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| level    | an optional positive integer giving the level of grouping to be used in extracting the coefficients from an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| data     | an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| which    | an optional positive integer or character vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| FUN      | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable. |

`omitGroupingFactor` an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

`subset` an optional expression specifying a subset

`...` some methods for this generic require additional arguments. None are used in this method.

### Value

a data frame inheriting from class `"coef.lme"` with the estimated coefficients at level `level` and, optionally, other covariates summarized over groups. The returned object also inherits from classes `"ranef.lme"` and `"data.frame"`.

|--------------------------|------------------------------------|
| <code>coef.lmList</code> | <i>Extract lmList Coefficients</i> |
|--------------------------|------------------------------------|

---

### Description

The coefficients of each `lm` object in the object list are extracted and organized into a data frame, with rows corresponding to the `lm` components and columns corresponding to the coefficients. Optionally, the returned data frame may be augmented with covariates summarized over the groups associated with the `lm` components.

### Usage

```
S3 method for class 'lmList'
coef(object, augFrame, data, which, FUN,
 omitGroupingFactor, ...)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object             | an object inheriting from class " <a href="#">lmList</a> ", representing a list of lm objects with a common model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| augFrame           | an optional logical value. If TRUE, the returned data frame is augmented with variables defined in the data frame used to produce object; else, if FALSE, only the coefficients are returned. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| data               | an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| which              | an optional positive integer or character vector specifying which columns of the data frame used to produce object should be used in the augmentation of the returned data frame. Defaults to all variables in the data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| FUN                | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing the data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable. |
| omitGroupingFactor | an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ...                | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Value**

a data frame inheriting from class "coef.lmList" with the estimated coefficients for each "lm" component of object and, optionally, other covariates summarized over the groups corresponding to the "lm" components. The returned object also inherits from classes "ranef.lmList" and "data.frame".

|------------------|------------------------------------------------|
| coef.modelStruct | <i>Extract modelStruct Object Coefficients</i> |
|------------------|------------------------------------------------|

---

**Description**

This method function extracts the coefficients associated with each component of the modelStruct list.

**Usage**

```
S3 method for class 'modelStruct'
coef(object, unconstrained, ...)
S3 replacement method for class 'modelStruct'
coef(object, ...) <- value
```

**Arguments**

|               |                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object        | an object inheriting from class "modelStruct", representing a list of model components, such as " <a href="#">corStruct</a> " and " <a href="#">varFunc</a> " objects.                                                         |
| unconstrained | a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE. |
| value         | a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef{object} and must be given in unconstrained form.                                            |
| ...           | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                      |

**Value**

a vector with all coefficients corresponding to the components of object.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using [Initialize](#)) before new values can be assigned to its coefficients.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

| coef.varFunc | <i>varFunc Object Coefficients</i> |
|--------------|------------------------------------|

---

Description

This method function extracts the coefficients associated with the variance function structure represented by object.

Usage

```
S3 method for class 'varFunc'
coef(object, unconstrained, allCoef, ...)
S3 replacement method for class 'varIdent'
coef(object, ...) <- value
```

Arguments

|               |                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object        | an object inheriting from class " <b>varFunc</b> " representing a variance function structure.                                                                                                                                                               |
| unconstrained | a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", generally constrained form. Defaults to TRUE.                               |
| allCoef       | a logical value. If FALSE only the coefficients which may vary during the optimization are returned. If TRUE all coefficients are returned. Defaults to FALSE.                                                                                               |
| value         | a vector with the replacement values for the coefficients associated with object. It must be have the same length of coef{object} and must be given in unconstrained form. Object must be initialized before new values can be assigned to its coefficients. |
| ...           | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                    |

Value

a vector with the coefficients corresponding to object.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value.

Author(s)

José Pinheiro and Douglas Bates

**Examples**

```
vf1 <- varPower(1)
coef(vf1)
coef(vf1) <- 2
```

collapse

*Collapse According to Groups***Description**

This function is generic; method functions can be written to handle specific classes of objects. Currently, only a groupedData method is available.

**Usage**

```
collapse(object, ...)
```

**Arguments**

**object**                    an object to be collapsed, usually a data frame.  
**...**                    some methods for the generic may require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

collapse.groupedData

*Collapse a groupedData Object***Description**

If object has a single grouping factor, it is returned unchanged. Else, it is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor.

**Usage**

```
S3 method for class 'groupedData'
collapse(object, collapseLevel, displayLevel,
 outer, inner, preserve, FUN, subset, ...)
```

**Arguments**

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>        | an object inheriting from class <code>groupedData</code> , generally with multiple grouping factors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>collapseLevel</code> | an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>displayLevel</code>  | an optional positive integer or character string indicating the grouping level to use as the grouping factor for the collapsed data. Default is <code>collapseLevel</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>outer</code>         | an optional logical value or one-sided formula, indicating covariates that are outer to the <code>displayLevel</code> grouping factor. If equal to <code>TRUE</code> , the <code>displayLevel</code> element <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>inner</code>         | an optional logical value or one-sided formula, indicating a covariate that is inner to the <code>displayLevel</code> grouping factor. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>preserve</code>      | an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the <code>collapseLevel</code> grouping factor. The collapsing factor is obtained by pasting together the levels of the <code>collapseLevel</code> grouping factor and the values of the covariate to be preserved. Default is <code>NULL</code> , meaning that no covariates need to be preserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>FUN</code>           | an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in <code>object</code> that vary within the groups defined by <code>collapseLevel</code> . Invariant variables are always summarized by group using the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the data such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| <code>subset</code>        | an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be preserved in the collapsed data. Default is <code>NULL</code> , meaning that all levels are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>...</code>           | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Value**

a `groupedData` object with a single grouping factor given by the `displayLevel` grouping factor, resulting from collapsing `object` over the levels of the `collapseLevel` grouping factor.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[groupedData](#), [plot.nmGroupedData](#)

**Examples**

```
collapsing by Dog
collapse(Pixel, collapseLevel = 1)
same as collapse(Pixel, collapseLevel = "Dog")
```

---

compareFits

*Compare Fitted Objects*

---

**Description**

The columns in object1 and object2 are put together in matrices which allow direct comparison of the individual elements for each object. Missing columns in either object are replaced by NAs.

**Usage**

```
compareFits(object1, object2, which)
```

**Arguments**

object1, object2

data frames, or matrices, with the same row names, but possibly different column names. These will usually correspond to coefficients from fitted objects with a grouping structure (e.g. lme and lmList objects).

which

an optional integer or character vector indicating which columns in object1 and object2 are to be used in the returned object. Defaults to all columns.

**Value**

a three-dimensional array, with the third dimension given by the number of unique column names in either object1 or object2. To each column name there corresponds a matrix with as many rows as the rows in object1 and two columns, corresponding to object1 and object2. The returned object inherits from class compareFits.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[plot.compareFits](#), [pairs.compareFits](#), [comparePred](#), [coef](#), [random.effects](#)

**Examples**

```
fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
(cF12 <- compareFits(coef(fm1), coef(fm2)))
```

---

|             |                            |
|-------------|----------------------------|
| comparePred | <i>Compare Predictions</i> |
|-------------|----------------------------|

---

**Description**

Predicted values are obtained at the specified values of primary for each object. If either object1 or object2 have a grouping structure (i.e. `getGroups(object)` is not `NULL`), predicted values are obtained for each group. When both objects determine groups, the group levels must be the same. If other covariates besides primary are used in the prediction model, their group-wise averages (numeric covariates) or most frequent values (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

**Usage**

```
comparePred(object1, object2, primary, minimum, maximum,
 length.out, level, ...)
```

**Arguments**

|                  |                                                                                                                                                                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object1, object2 | fitted model objects, from which predictions can be extracted using the <code>predict</code> method.                                                                                                                                                                    |
| primary          | an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate the objects (using <code>getCovariate</code> ), it will be used as primary. |
| minimum          | an optional lower limit for the primary covariate. Defaults to <code>min(primary)</code> , after primary is evaluated in the data used in fitting object1.                                                                                                              |
| maximum          | an optional upper limit for the primary covariate. Defaults to <code>max(primary)</code> , after primary is evaluated in the data used in fitting object1.                                                                                                              |
| length.out       | an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.                                                                                                                                                   |
| level            | an optional integer specifying the desired prediction level. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Only one level can be specified. Defaults to the innermost level.              |
| ...              | some methods for the generic may require additional arguments.                                                                                                                                                                                                          |

**Value**

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: the objects' names are used to classify the predicted values and original is used for the observed values. The returned object inherits from classes `comparePred` and `augPred`.

**Note**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[augPred](#), [getGroups](#)

**Examples**

```
fm1 <- lme(distance ~ age * Sex, data = Orthodont, random = ~ age)
fm2 <- update(fm1, distance ~ age)
comparePred(fm1, fm2, length.out = 2)
```

---

corAR1

*AR(1) Correlation Structure*

---

**Description**

This function is a constructor for the corAR1 class, representing an autocorrelation structure of order 1. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corAR1(value, form, fixed)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | the value of the lag 1 autocorrelation, which must be between -1 and 1. Defaults to 0 (no autocorrelation).                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| form  | a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                      |

**Value**

an object of class corAR1, representing an autocorrelation structure of order 1.

corARMA

*ARMA(p,q) Correlation Structure***Description**

This function is a constructor for the `corARMA` class, representing an autocorrelation-moving average correlation structure of order (p, q). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corARMA(value, form, p, q, fixed)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | a vector with the values of the autoregressive and moving average parameters, which must have length $p + q$ and all elements between -1 and 1. Defaults to a vector of zeros, corresponding to uncorrelated observations.                                                                                                                                                                                                                                                                                                                                                     |
| form  | a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| p, q  | non-negative integers specifying respectively the autoregressive order and the moving average order of the ARMA structure. Both default to 0, but at least one should be $> 0$ .                                                                                                                                                                                                                                                                                                                                                                                               |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                        |

**Value**

an object of class `corARMA`, representing an autocorrelation-moving average correlation structure.

## Examples

```
ARMA(1,2) structure, with observation order as a covariate and
Mare as grouping factor
cs1 <- corARMA(c(0.2, 0.3, -0.1), form = ~ 1 | Mare, p = 1, q = 2)

Pinheiro and Bates, p. 237
cs1ARMA <- corARMA(0.4, form = ~ 1 | Subject, q = 1)
cs1ARMA <- Initialize(cs1ARMA, data = Orthodont)
corMatrix(cs1ARMA)

cs2ARMA <- corARMA(c(0.8, 0.4), form = ~ 1 | Subject, p=1, q=1)
cs2ARMA <- Initialize(cs2ARMA, data = Orthodont)
corMatrix(cs2ARMA)

Pinheiro and Bates use in nlme:
from p. 240 needed on p. 396
fm10var.lme <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time),
 data = Ovary, random = pdDiag(~sin(2*pi*Time)))
fm50var.lme <- update(fm10var.lme,
 correlation = corARMA(p = 1, q = 1))

p. 396
fm10var.nlme <- nlme(follicles~
 A+B*sin(2*pi*w*Time)+C*cos(2*pi*w*Time),
 data=Ovary, fixed=A+B+C+w~1,
 random=pdDiag(A+B+w~1),
 start=c(fixef(fm50var.lme), 1))
p. 397
fm30var.nlme <- update(fm10var.nlme,
 correlation=corARMA(p=0, q=2))
```

corCAR1

*Continuous AR(1) Correlation Structure*

## Description

This function is a constructor for the `corCAR1` class, representing an autocorrelation structure of order 1, with a continuous time covariate. Objects created using this constructor must be later initialized using the appropriate `Initialize` method.

## Usage

```
corCAR1(value, form, fixed)
```

## Arguments

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | the correlation between two observations one unit of time apart. Must be between 0 and 1. Defaults to 0.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| form  | a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . Covariates for this correlation structure need not be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |

**fixed** an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

corClasses

*Correlation Structure Classes*

---

### Description

Standard classes of correlation structures (`corStruct`) available in the **nlme** package.

Value

Available standard classes:

|             |                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------|
| corAR1      | autoregressive process of order 1.                                                                                 |
| corARMA     | autoregressive moving average process, with arbitrary orders for the autoregressive and moving average components. |
| corCAR1     | continuous autoregressive process (AR(1) process for a continuous time covariate).                                 |
| corCompSymm | compound symmetry structure corresponding to a constant correlation.                                               |
| corExp      | exponential spatial correlation.                                                                                   |
| corGaus     | Gaussian spatial correlation.                                                                                      |
| corLin      | linear spatial correlation.                                                                                        |
| corRatio    | Rational quadratics spatial correlation.                                                                           |
| corSpher    | spherical spatial correlation.                                                                                     |
| corSymm     | general correlation matrix, with no additional structure.                                                          |

Note

Users may define their own corStruct classes by specifying a constructor function and, at a minimum, methods for the functions [corMatrix](#) and [coef](#). For examples of these functions, see the methods for classes corSymm and corAR1.

|-------------|------------------------------------------------|
| corCompSymm | <i>Compound Symmetry Correlation Structure</i> |
|-------------|------------------------------------------------|

---

Description

This function is a constructor for the corCompSymm class, representing a compound symmetry structure corresponding to uniform correlation. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corCompSymm(value, form, fixed)

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | the correlation between any two correlated observations. Defaults to 0.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| form  | a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                     |

**Value**

an object of class corCompSymm, representing a compound symmetry correlation structure.

covariate is observation order and grouping factor is Subject
cs1 <- corCompSymm(0.5, form = ~ 1 | Subject)
cs1 # Uninitialized ...

Pinheiro and Bates, p. 225
cs1CompSymm <- corCompSymm(value = 0.3, form = ~ 1 | Subject)
cs2CompSymm <- corCompSymm(value = 0.3, form = ~ age | Subject)
cs1CompSymm <- Initialize(cs1CompSymm, data = Orthodont)
corMatrix(cs1CompSymm)
```

corExp

*Exponential Correlation Structure***Description**

This function is a constructor for the "corExp" class, representing an exponential spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $\exp(-r/d)$  when no nugget effect is present and  $(1 - n) \exp(-r/d)$  when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

```
corExp(value, form, nugget, metric, fixed)
```

**Arguments**

- |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value  | an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form   | a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.                                                                                                                                                                                                                      |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                                                                                                                                                                                                                       |
| fixed  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Value**

an object of class "corExp", also inheriting from class "corSpatial", representing an exponential spatial correlation structure.

|-----------|---------------------------------------|
| corFactor | <i>Factor of a Correlation Matrix</i> |
|-----------|---------------------------------------|

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "corStruct" classes, see '[corClasses](#)'.

**Usage**

```
corFactor(object, ...)
```

**Arguments**

|        |                                                                      |
|--------|----------------------------------------------------------------------|
| object | an object from which a correlation matrix can be extracted.          |
| ...    | some methods for this generic function require additional arguments. |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

|                     |                                            |
|---------------------|--------------------------------------------|
| corFactor.corStruct | <i>Factor of a corStruct Object Matrix</i> |
|---------------------|--------------------------------------------|

---

**Description**

This method function extracts a transpose inverse square-root factor, or a series of transpose inverse square-root factors, of the correlation matrix, or list of correlation matrices, represented by object. Letting  $\Sigma$  denote a correlation matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This method extracts  $L^{-t}$ .

**Usage**

```
S3 method for class 'corStruct'
corFactor(object, ...)
```

**Arguments**

|        |                                                                                                                                                                        |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">corStruct</a> " representing a correlation structure, which must have been initialized (using <code>Initialize</code> ). |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                              |

**Value**

If the correlation structure does not include a grouping factor, the returned value will be a vector with a transpose inverse square-root factor of the correlation matrix associated with object stacked column-wise. If the correlation structure includes a grouping factor, the returned value will be a vector with transpose inverse square-root factors of the correlation matrices for each group, stacked by group and stacked column-wise within each group.

**Note**

This method function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `corMatrix` method function can be used to obtain transpose inverse square-root factors in matrix form.

cs1 <- corAR1(form = ~1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
corFactor(cs1)
```

---

corGaus

*Gaussian Correlation Structure*

---

**Description**

This function is a constructor for the `corGaus` class, representing a Gaussian spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $\exp(-(r/d)^2)$  when no nugget effect is present and  $(1 - n) \exp(-(r/d)^2)$  when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate ‘`Initialize`’ method.

**Usage**

```
corGaus(value, form, nugget, metric, fixed)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the Gaussian correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>form</code>   | a one sided formula of the form <code>~ S1+...+Sp</code> , or <code>~ S1+...+Sp   g</code> , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| <code>nugget</code> | an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>metric</code> | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                                                          |
| <code>fixed</code>  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                           |

**Value**

corLin

*Linear Correlation Structure*

## Description

This function is a constructor for the `corLin` class, representing a linear spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r < d$  apart is  $1 - (r/d)$  when no nugget effect is present and  $(1 - n)(1 - (r/d))$  when a nugget effect is assumed. If  $r \geq d$  the correlation is zero. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

## Usage

```
corLin(value, form, nugget, metric, fixed)
```

## Arguments

- |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value  | an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the linear correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form   | a one sided formula of the form <code>~ S1+...+Sp</code> , or <code>~ S1+...+Sp   g</code> , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.                                                                                                                                                                                                                                         |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| fixed  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Value**

an object of class `corLin`, also inheriting from class `corSpatial`, representing a linear spatial correlation structure.

```

---

corMatrix

---

*Extract Correlation Matrix*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "corStruct" classes, see '[cor-Classes](#)'.

**Usage**

```
corMatrix(object, ...)
```

**Arguments**

object            an object for which a correlation matrix can be extracted.  
 ...              some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[corMatrix.corStruct](#), [corMatrix.pdMat](#), [corMatrix.reStruct](#)

---

corMatrix.corStruct     *Matrix of a corStruct Object*

---

**Description**

This method function extracts the correlation matrix (or its transpose inverse square-root factor), or list of correlation matrices (or their transpose inverse square-root factors) corresponding to covariate and object. Letting  $\Sigma$  denote a correlation matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . When `corr = FALSE`, this method extracts  $L^{-t}$ .

**Usage**

```
S3 method for class 'corStruct'
corMatrix(object, covariate, corr, ...)
```

**Arguments**

object            an object inheriting from class "[corStruct](#)" representing a correlation structure.  
 covariate        an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to `getCovariate(object)`.  
 corr             a logical value. If TRUE the function returns the correlation matrix, or list of correlation matrices, represented by object. If FALSE the function returns a transpose inverse square-root of the correlation matrix, or a list of transpose inverse square-root factors of the correlation matrices.  
 ...              some methods for this generic require additional arguments. None are used in this method.

**Value**

If covariate is a vector (matrix), the returned value will be an array with the corresponding correlation matrix (or its transpose inverse square-root factor). If the covariate is a list of vectors (matrices), the returned value will be a list with the correlation matrices (or their transpose inverse square-root factors) corresponding to each component of covariate.

|            |                                                        |
|------------|--------------------------------------------------------|
| corNatural | <i>General correlation in natural parameterization</i> |
|------------|--------------------------------------------------------|

---

**Description**

This function is a constructor for the `corNatural` class, representing a general correlation structure in the “natural” parameterization, which is described under [pdNatural](#). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corNatural(value, form, fixed)
```

**Arguments**

- |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | an optional vector with the parameter values. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).                                                                                                                                                                                                                                                                                                                                                          |
| form  | a one sided formula of the form <code>~ t</code> , or <code>~ t   g</code> , specifying a time covariate <code>t</code> and, optionally, a grouping factor <code>g</code> . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                                                   |

**Value**

an object of class `corNatural` representing a general correlation structure.

|----------|-------------------------------------------------|
| corRatio | <i>Rational Quadratic Correlation Structure</i> |
|----------|-------------------------------------------------|

---

Description

This function is a constructor for the `corRatio` class, representing a rational quadratic spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $1/(1 + (r/d)^2)$  when no nugget effect is present and  $(1 - n)/(1 + (r/d)^2)$  when a nugget effect is assumed. Objects created using this constructor need to be later initialized using the appropriate `Initialize` method.

Usage

```
corRatio(value, form, nugget, metric, fixed)
```

Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value  | an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the rational quadratic correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form   | a one sided formula of the form <code>~ S1+...+Sp</code> , or <code>~ S1+...+Sp   g</code> , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.                                                                                                                                                                                                                                                     |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**fixed** an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

### Value

an object of class `corRatio`, also inheriting from class `corSpatial`, representing a rational quadratic spatial correlation structure.

 nugget = TRUE))
```

corSpatial

*Spatial Correlation Structure***Description**

This function is a constructor for the `corSpatial` class, representing a spatial correlation structure. This class is "virtual", having four "real" classes, corresponding to specific spatial correlation structures, associated with it: `corExp`, `corGaus`, `corLin`, `corRatio`, and `corSpher`. The returned object will inherit from one of these "real" classes, determined by the `type` argument, and from the "virtual" `corSpatial` class. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSpatial(value, form, nugget, type, metric, fixed)
```

**Arguments**

- |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value  | an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the spatial correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form   | a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.                                                                                                                                                                                                                                                   |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| type   | an optional character string specifying the desired type of correlation structure. Available types include "spherical", "exponential", "gaussian", "linear", and "rational". See the documentation on the functions <code>corSpher</code> , <code>corExp</code> , <code>corGaus</code> , <code>corLin</code> , and <code>corRatio</code> for a description of these correlation structures. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "spherical".                                                                                                                                                                                                                                                                                                                              |
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| fixed  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Value**

an object of class determined by the `type` argument and also inheriting from class `corSpatial`, representing a spatial correlation structure.

```

---

corSpher

*Spherical Correlation Structure*

---

**Description**

This function is a constructor for the `corSpher` class, representing a spherical spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r < d$  apart is  $1 - 1.5(r/d) + 0.5(r/d)^3$  when no nugget effect is present and  $(1 - n)(1 - 1.5(r/d) + 0.5(r/d)^3)$  when a nugget effect is assumed. If  $r \geq d$  the correlation is zero. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSpher(value, form, nugget, metric, fixed)
```

**Arguments**

**value** an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the spherical correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| form   | a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                  |
| fixed  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                 |

**Value**

an object of class `corSpher`, also inheriting from class `corSpatial`, representing a spherical spatial correlation structure.

corSymm

*General Correlation Structure***Description**

This function is a constructor for the `corSymm` class, representing a general correlation structure. The internal representation of this structure, in terms of unconstrained parameters, uses the spherical parametrization defined in Pinheiro and Bates (1996). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSymm(value, form, fixed)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | an optional vector with the parameter values. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).                                                                                                                                                                                                                                                                                                                                                          |
| form  | a one sided formula of the form <code>~ t</code> , or <code>~ t   g</code> , specifying a time covariate <code>t</code> and, optionally, a grouping factor <code>g</code> . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                                                   |

**Value**

an object of class `corSymm` representing a general correlation structure.

Covariate

---

*Assign Covariate Values*

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "[varFunc](#)" classes, see '[varClasses](#)'.

## Usage

```
covariate(object) <- value
```

**Arguments**

|        |                                                                 |
|--------|-----------------------------------------------------------------|
| object | any object with a covariate component.                          |
| value  | a value to be assigned to the covariate associated with object. |

**Value**

will depend on the method function; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

|-------------------|---------------------------------|
| Covariate.varFunc | <i>Assign varFunc Covariate</i> |
|-------------------|---------------------------------|

---

**Description**

The covariate(s) used in the calculation of the weights of the variance function represented by object is (are) replaced by value. If object has been initialized, value must have the same dimensions as getCovariate(object).

**Usage**

```
S3 replacement method for class 'varFunc'
covariate(object) <- value
```

**Arguments**

|        |                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">varFunc</a> ", representing a variance function structure. |
| value  | a value to be assigned to the covariate associated with object.                                          |

**Value**

a varFunc object similar to object, but with its covariate attribute replaced by value.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|          |                        |
|----------|------------------------|
| Dialyzer | High-Flux Hemodialyzer |
|----------|------------------------|

---

**Description**

The Dialyzer data frame has 140 rows and 5 columns.

**Format**

This data frame contains the following columns:

- Subject** an ordered factor with levels 10 < 8 < 2 < 6 < 3 < 5 < 9 < 7 < 1 < 4 < 17 < 20 < 11 < 12 < 16 < 13 < 14 < 18 < 15 < 19 giving the unique identifier for each subject
- QB** a factor with levels 200 and 300 giving the bovine blood flow rate (dL/min).
- pressure** a numeric vector giving the transmembrane pressure (dmHg).
- rate** the hemodialyzer ultrafiltration rate (mL/hr).
- index** index of observation within subject—1 through 7.

**Details**

Vonesh and Carter (1992) describe data measured on high-flux hemodialyzers to assess their *in vivo* ultrafiltration characteristics. The ultrafiltration rates (in mL/hr) of 20 high-flux dialyzers were measured at seven different transmembrane pressures (in dmHg). The *in vitro* evaluation of the dialyzers used bovine blood at flow rates of either 200~dl/min or 300~dl/min. The data, are also analyzed in Littell, Milliken, Stroup, and Wolfinger (1996).

|     |                                   |
|-----|-----------------------------------|
| Dim | Extract Dimensions from an Object |
|-----|-----------------------------------|

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `"corSpatial"`, `"corStruct"`, `"pdCompSymm"`, `"pdDiag"`, `"pdIdent"`, `"pdMat"`, and `"pdSymm"`.

**Usage**

```
Dim(object, ...)
```

**Arguments**

|        |                                                                      |
|--------|----------------------------------------------------------------------|
| object | any object for which dimensions can be extracted.                    |
| ...    | some methods for this generic function require additional arguments. |

**Value**

will depend on the method function used; see the appropriate documentation.

**Note**

If dim allowed more than one argument, there would be no need for this generic function.

|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">corStruct</a> ", representing a correlation structure.                                                            |
| groups | an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                       |

**Value**

a list with components:

|          |                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------|
| N        | length of groups                                                                                     |
| M        | number of groups                                                                                     |
| maxLen   | maximum number of observations in a group                                                            |
| sumLenSq | sum of the squares of the number of observations per group                                           |
| len      | an integer vector with the number of observations per group                                          |
| start    | an integer vector with the starting position for the observations in each group, beginning from zero |

## Earthquake

*Earthquake Intensity***Description**

The Earthquake data frame has 182 rows and 5 columns.

**Format**

This data frame contains the following columns:

**Quake** an ordered factor with levels 20 < 16 < 14 < 10 < 3 < 8 < 23 < 22 < 6 < 13 < 7 < 21 < 18 < 15 < 4 < 12 < 19 < 5 < 9 < 1 < 2 < 17 < 11 indicating the earthquake on which the measurements were made.

**Richter** a numeric vector giving the intensity of the earthquake on the Richter scale.

**distance** the distance from the seismological measuring station to the epicenter of the earthquake (km).

**soil** a factor with levels 0 and 1 giving the soil condition at the measuring station, either soil or rock.

**accel** maximum horizontal acceleration observed (g).

**Details**

Measurements recorded at available seismometer locations for 23 large earthquakes in western North America between 1940 and 1980. They were originally given in Joyner and Boore (1981); are mentioned in Brillinger (1987); and are analyzed in Davidian and Giltinan (1995).

## ergoStool

*Ergometrics experiment with stool types***Description**

The ergoStool data frame has 36 rows and 3 columns.

**Format**

This data frame contains the following columns:

**effort** a numeric vector giving the effort (Borg scale) required to arise from a stool.

**Type** a factor with levels T1, T2, T3, and T4 giving the stool type.

**Subject** an ordered factor giving a unique identifier for the subject in the experiment.

**Details**

Devore (2000) cites data from an article in *Ergometrics* (1993, pp. 519-535) on “The Effects of a Pneumatic Stool and a One-Legged Stool on Lower Limb Joint Load and Muscular Activity.”

anova(fm1)
```

---

Fatigue

*Cracks caused by metal fatigue*

---

**Description**

The Fatigue data frame has 262 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Path** an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9 < 10 < 11 < 12 < 13 < 14 < 15 < 16 < 17 < 18 < 19 < 20 < 21 giving the test path (or test unit) number. The order is in terms of increasing failure time or decreasing terminal crack length.

**cycles** number of test cycles at which the measurement is made (millions of cycles).

**relLength** relative crack length (dimensionless).

**Details**

These data are given in Lu and Meeker (1993) where they state “We obtained the data in Table 1 visually from figure 4.5.2 on page 242 of Bogdanoff and Kozin (1985).” The data represent the growth of cracks in metal for 21 test units. An initial notch of length 0.90 inches was made on each unit which then was subjected to several thousand test cycles. After every 10,000 test cycles the crack length was measured. Testing was stopped if the crack length exceeded 1.60 inches, defined as a failure, or at 120,000 cycles.

fdHess

*Finite difference Hessian***Description**

Evaluate an approximate Hessian and gradient of a scalar function using finite differences.

**Usage**

```
fdHess(pars, fun, ...,
 .relStep = .Machine$double.eps^(1/3), minAbsPar = 0)
```

**Arguments**

|           |                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pars      | the numeric values of the parameters at which to evaluate the function fun and its derivatives.                                                                     |
| fun       | a function depending on the parameters pars that returns a numeric scalar.                                                                                          |
| ...       | Optional additional arguments to fun                                                                                                                                |
| .relStep  | The relative step size to use in the finite differences. It defaults to the cube root of .Machine\$double.eps                                                       |
| minAbsPar | The minimum magnitude of a parameter value that is considered non-zero. It defaults to zero meaning that any non-zero value will be considered different from zero. |

**Details**

This function uses a second-order response surface design known as a “Koschal design” to determine the parameter values at which the function is evaluated.

**Value**

A list with components

|          |                                                                  |
|----------|------------------------------------------------------------------|
| mean     | the value of function fun evaluated at the parameter values pars |
| gradient | an approximate gradient (of length length(pars)).                |
| Hessian  | a matrix whose upper triangle contains an approximate Hessian.   |

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
(fdH <- fdHess(c(12.3, 2.34), function(x) x[1]*(1-exp(-0.4*x[2]))))
stopifnot(length(fdH$ mean) == 1,
 length(fdH$ gradient) == 2,
 identical(dim(fdH$ Hessian), c(2L, 2L)))
```

---

|                  |                                          |
|------------------|------------------------------------------|
| fitted.glsStruct | <i>Calculate glsStruct Fitted Values</i> |
|------------------|------------------------------------------|

---

**Description**

The fitted values for the linear model represented by object are extracted.

**Usage**

```
S3 method for class 'glStruct'
fitted(object, glsFit, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">glStruct</a> ", representing a list of linear model components, such as corStruct and " <a href="#">varFunc</a> " objects.                                                                                    |
| glsFit | an optional list with components logLik (log-likelihood), beta (coefficients), sigma (standard deviation for error term), varBeta (coefficients' covariance matrix), fitted (fitted values), and residuals (residuals). Defaults to attr(object, "glsFit"). |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                   |

**Value**

a vector with the fitted values for the linear model represented by object.

**Note**

This method function is generally only used inside gls and fitted.gls.

|-------------------|-------------------------------------------|
| fitted.gnlsStruct | <i>Calculate gnlsStruct Fitted Values</i> |
|-------------------|-------------------------------------------|

---

**Description**

The fitted values for the nonlinear model represented by object are extracted.

**Usage**

```
S3 method for class 'gnlsStruct'
fitted(object, ...)
```

**Arguments**

- object      an object inheriting from class "[gnlsStruct](#)", representing a list of model components, such as `corStruct` and `varFunc` objects, and attributes specifying the underlying nonlinear model and the response variable.
- ...        some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the fitted values for the nonlinear model represented by `object`.

**Note**

This method function is generally only used inside `gnls` and `fitted.gnls`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gnls](#), [residuals.gnlsStruct](#)

---

|                         |                                  |
|-------------------------|----------------------------------|
| <code>fitted.lme</code> | <i>Extract lme Fitted Values</i> |
|-------------------------|----------------------------------|

---

**Description**

The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ .

**Usage**

```
S3 method for class 'lme'
fitted(object, level, asList, ...)
```

**Arguments**

- object      an object inheriting from class "[lme](#)", representing a fitted linear mixed-effects model.
- level      an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- asList      an optional logical value. If TRUE and a single value is given in `level`, the returned object is a list with the fitted values split by groups; else the returned value is either a vector or a data frame, according to the length of `level`. Defaults to FALSE.
- ...        some methods for this generic require additional arguments. None are used in this method.

**Value**

If a single level of grouping is specified in `level`, the returned value is either a list with the fitted values split by groups (`asList = TRUE`) or a vector with the fitted values (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the fitted values at different levels and the grouping factors. For a vector or data frame result the `napredict` method is applied.

|                            |                                     |
|----------------------------|-------------------------------------|
| <code>fitted.lmList</code> | <i>Extract lmList Fitted Values</i> |
|----------------------------|-------------------------------------|

---

**Description**

The fitted values are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

**Usage**

```
S3 method for class 'lmList'
fitted(object, subset, asList, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>"lmList"</code> , representing a list of <code>lm</code> objects with a common model.                                                                                                  |
| <code>subset</code> | an optional character or integer vector naming the <code>lm</code> components of <code>object</code> from which the fitted values are to be extracted. Default is <code>NULL</code> , in which case all components are used. |
| <code>asList</code> | an optional logical value. If <code>TRUE</code> , the returned object is a list with the fitted values split by groups; else the returned value is a vector. Defaults to <code>FALSE</code> .                                |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                    |

Value

a list with components given by the fitted values of each `lm` component of `object`, or a vector with the fitted values for all `lm` components of `object`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
fitted(fm1)
```

---

|                   |                                           |
|-------------------|-------------------------------------------|
| fitted.nlmeStruct | <i>Calculate nlmeStruct Fitted Values</i> |
|-------------------|-------------------------------------------|

---

Description

The fitted values at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters. The resulting values estimate the predictions at level  $i$ .

Usage

```
S3 method for class 'nlmeStruct'
fitted(object, level, conLin, ...)
```

Arguments

- |                     |                                                                                                                                                                                                                                                                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class " <a href="#">nlmeStruct</a> ", representing a list of mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects, plus attributes specifying the underlying nonlinear model and the response variable.                                      |
| <code>level</code>  | an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.                         |
| <code>conLin</code> | an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( $X$ ) combined with a response vector ( $y$ ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying nlme model. Defaults to <code>attr(object, "conLin")</code> . |
| <code>...</code>    | additional arguments that could be given to this method. None are used.                                                                                                                                                                                                                                                                     |

**Value**

if a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

**Note**

This method function is generally only used inside `nlme` and `fitted.nlme`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

fixed.effects

*Extract Fixed Effects*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmList` and `lme`.

`fixed.effects` is an alias for `fixef`; methods are implemented for the latter.

**Usage**

```
fixed.effects(object, ...)
fixef(object, ...)
```

**Arguments**

|                     |                                                                              |
|---------------------|------------------------------------------------------------------------------|
| <code>object</code> | any fitted model object from which fixed effects estimates can be extracted. |
| <code>...</code>    | some methods for this generic function require additional arguments.         |

**Value**

will depend on the method function used; see the appropriate documentation.

**References**

|--------------|-------------------------------------|
| fixef.lmList | <i>Extract lmList Fixed Effects</i> |
|--------------|-------------------------------------|

---

**Description**

The average of the coefficients corresponding to the `lm` components of object is calculated.

**Usage**

```
S3 method for class 'lmList'
fixef(object, ...)
```

**Arguments**

|        |                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">lmList</a> ", representing a list of <code>lm</code> objects with a common model. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                       |

**Value**

a vector with the average of the individual `lm` coefficients in object.

|-------------------|----------------------------------|
| formula.pdBlocked | <i>Extract pdBlocked Formula</i> |
|-------------------|----------------------------------|

---

**Description**

The formula attributes of the `pdMat` elements of `x` are extracted and returned as a list, in case `asList=TRUE`, or converted to a single one-sided formula when `asList=FALSE`. If the `pdMat` elements do not have a formula attribute, a `NULL` value is returned.

**Usage**

```
S3 method for class 'pdBlocked'
formula(x, asList, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | an object inheriting from class "pdBlocked", representing a positive definite block diagonal matrix.                                                                                                                                         |
| <code>asList</code> | an optional logical value. If TRUE, a list with the formulas for the individual block diagonal elements of <code>x</code> is returned; else, if FALSE, a one-sided formula combining all individual formulas is returned. Defaults to FALSE. |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                    |

**Value**

a list of one-sided formulas, or a single one-sided formula, or NULL.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[pdBlocked](#), [pdMat](#)

**Examples**

```
pd1 <- pdBlocked(list(~ age, ~ Sex - 1))
formula(pd1)
formula(pd1, asList = TRUE)
```

---

|               |                              |
|---------------|------------------------------|
| formula.pdMat | <i>Extract pdMat Formula</i> |
|---------------|------------------------------|

---

**Description**

This method function extracts the formula associated with a `pdMat` object, in which the column and row names are specified.

**Usage**

```
S3 method for class 'pdMat'
formula(x, asList, ...)
```

**Arguments**

|                     |                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------|
| <code>x</code>      | an object inheriting from class " <a href="#">pdMat</a> ", representing a positive definite matrix. |
| <code>asList</code> | logical. Should the <code>asList</code> argument be applied to each of the components? Never used.  |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.           |

**Value**

if `x` has a `formula` attribute, its value is returned, else NULL is returned.

**Note**

Because factors may be present in `formula(x)`, the `pdMat` object needs to have access to a data frame where the variables named in the formula can be evaluated, before it can resolve its row and column names from the formula.

`formula.reStruct`

*Extract reStruct Object Formula*

---

**Description**

This method function extracts a formula from each of the components of `x`, returning a list of formulas.

**Usage**

```
S3 method for class 'reStruct'
formula(x, asList, ...)
```

**Arguments**

|                     |                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects. |
| <code>asList</code> | logical. Should the <code>asList</code> argument be applied to each of the components?                                                                        |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                     |

**Value**

a list with the formulas of each component of `x`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
rs1 <- reStruct(list(A = pdDiag(diag(2), ~age), B = ~1))
formula(rs1)
```

gapply

*Apply a Function by Groups***Description**

Applies the function to the distinct sets of rows of the data frame defined by groups.

**Usage**

```
gapply(object, which, FUN, form, level, groups, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object to which the function will be applied - usually a groupedData object or a data.frame. Must inherit from class "data.frame".                                                                                                               |
| which  | an optional character or positive integer vector specifying which columns of object should be used with FUN. Defaults to all columns in object.                                                                                                     |
| FUN    | function to apply to the distinct sets of rows of the data frame object defined by the values of groups.                                                                                                                                            |
| form   | an optional one-sided formula that defines the groups. When this formula is given the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to formula(object). |
| level  | an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.                                                                     |
| groups | an optional factor that will be used to split the rows into groups. Defaults to getGroups(object, form, level).                                                                                                                                     |
| ...    | optional additional arguments to the summary function FUN. Often it is helpful to specify na.rm = TRUE.                                                                                                                                             |

**Value**

Returns a data frame with as many rows as there are levels in the groups argument.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|----------|-----------------------------------|
| Gasoline | <i>Refinery yield of gasoline</i> |
|----------|-----------------------------------|

---

Description

The Gasoline data frame has 32 rows and 6 columns.

Format

This data frame contains the following columns:

- yield** a numeric vector giving the percentage of crude oil converted to gasoline after distillation and fractionation
- endpoint** a numeric vector giving the temperature (degrees F) at which all the gasoline is vaporized
- Sample** an ordered factor giving the inferred crude oil sample number
- API** a numeric vector giving the crude oil gravity (degrees API)
- vapor** a numeric vector giving the vapor pressure of the crude oil (lbf/in<sup>2</sup>)
- ASTM** a numeric vector giving the crude oil 10% point ASTM—the temperature at which 10% of the crude oil has become vapor.

Details

Prater (1955) provides data on crude oil properties and gasoline yields. Atkinson (1985) uses these data to illustrate the use of diagnostics in multiple regression analysis. Three of the covariates—API, vapor, and ASTM—measure characteristics of the crude oil used to produce the gasoline. The other covariate — endpoint—is a characteristic of the refining process. Daniel and Wood (1980) notice that the covariates characterizing the crude oil occur in only ten distinct groups and conclude that the data represent responses measured on ten different crude oil samples.

**Description**

This method function extracts the covariate(s) associated with `object`.

**Usage**

```
S3 method for class 'corStruct'
getCovariate(object, form, data)
```

**Arguments**

|        |                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>corStruct</code> representing a correlation structure.                                                                                     |
| form   | this argument is included to make the method function compatible with the generic. It will be assigned the value of <code>formula(object)</code> and should not be modified.     |
| data   | an optional data frame in which to evaluate the variables defined in <code>form</code> , in case <code>object</code> is not initialized and the covariate needs to be evaluated. |

**Value**

when the correlation structure does not include a grouping factor, the returned value will be a vector or a matrix with the covariate(s) associated with `object`. If a grouping factor is present, the returned value will be a list of vectors or matrices with the covariate(s) corresponding to each grouping level. For spatial correlation structures, this extracts the *distances* implied by the covariates, and excludes 1-observation groups.

**Examples**

```
cs1 <- corAR1(form = ~ 1 | Subject)
getCovariate(cs1, data = Orthodont)
```

---

```
getCovariate.data.frame
```

*Extract Data Frame Covariate*

---

**Description**

The right hand side of `form`, stripped of any conditioning expression (i.e. an expression following a `|` operator), is evaluated in `object`.

**Usage**

```
S3 method for class 'data.frame'
getCovariate(object, form, data)
```

**Arguments**

|        |                                                                                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>data.frame</code> .                                                          |
| form   | an optional formula specifying the covariate to be evaluated in object. Defaults to <code>formula(object)</code> . |
| data   | some methods for this generic require a separate data frame. Not used in this method.                              |

**Value**

the value of the right hand side of `form`, stripped of any conditional expression, evaluated in object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|             |                                |
|-------------|--------------------------------|
| getData.gls | <i>Extract gls Object Data</i> |
|-------------|--------------------------------|

---

**Description**

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

**Usage**

```
S3 method for class 'gl'
getData(object)
```

**Arguments**

|        |                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>gl</code> s, representing a generalized least squares fitted linear model. |
|--------|------------------------------------------------------------------------------------------------------------------|

**Value**

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced object) is returned; else, `NULL` is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gls](#), [getData](#)

**Examples**

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
 correlation = corAR1(form = ~ 1 | Mare))
getData(fm1)
```

---

getData.lme

*Extract lme Object Data*

---

**Description**

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

**Usage**

```
S3 method for class 'lme'
getData(object)
```

**Arguments**

object                    an object inheriting from class lme, representing a linear mixed-effects fitted model.

**Value**

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with na.action and subset applied to it, if also present in the call that produced object) is returned; else, NULL is returned.

Note that as from version 3.1-102, this only omits rows omitted in the fit if na.action = na.omit, and does not omit at all if na.action = na.exclude. That is generally what is wanted for plotting, the main use of this function.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|----------------|-----------------------------------|
| getData.lmList | <i>Extract lmList Object Data</i> |
|----------------|-----------------------------------|

---

**Description**

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

**Usage**

```
S3 method for class 'lmList'
getData(object)
```

**Arguments**

|        |                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model. |
|--------|---------------------------------------------------------------------------------------------------------------------------|

**Value**

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced object) is returned; else, `NULL` is returned.

getGroups.corStruct     *Extract corStruct Groups*

---

**Description**

This method function extracts the grouping factor associated with object, if any is present.

**Usage**

```
S3 method for class 'corStruct'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |                                                                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class corStruct representing a correlation structure.                                                                                 |
| form   | this argument is included to make the method function compatible with the generic. It will be assigned the value of formula(object) and should not be modified. |
| level  | this argument is included to make the method function compatible with the generic and is not used.                                                              |
| data   | an optional data frame in which to evaluate the variables defined in form, in case object is not initialized and the grouping factor needs to be evaluated.     |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/ '.                                                   |

**Value**

if a grouping factor is present in the correlation structure represented by object, the function returns the corresponding factor vector; else the function returns NULL.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[getGroups](#)

**Examples**

```
cs1 <- corAR1(form = ~ 1 | Subject)
getGroups(cs1, data = Orthodont)
```

---

getGroups.data.frame    *Extract Groups from a Data Frame*

---

**Description**

Each variable named in the expression after the | operator on the right hand side of form is evaluated in object. If more than one variable is indicated in level they are combined into a data frame; else the selected variable is returned as a vector. When multiple grouping levels are defined in form and level > 1, the levels of the returned factor are obtained by pasting together the levels of the grouping factors of level greater or equal to level, to ensure their uniqueness.

**Usage**

```
S3 method for class 'data.frame'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>data.frame</code> .                                                                                                                        |
| form   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . |
| level  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. Defaults to all levels of nesting.                       |
| data   | unused                                                                                                                                                                           |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .                                                       |

**Value**

either a data frame with columns given by the grouping factors indicated in `level`, from outer to inner, or, when a single level is requested, a factor representing the selected grouping factor.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
 correlation = corAR1(form = ~ 1 | Mare))
getGroups(fm1)
```

---

getGroups.lme

*Extract lme Object Groups*

---

**Description**

The grouping factors corresponding to the linear mixed-effects model represented by `object` are extracted. If more than one level is indicated in `level`, the corresponding grouping factors are combined into a data frame; else the selected grouping factor is returned as a vector.

**Usage**

```
S3 method for class 'lme'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |                                                                                                                                                 |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                            |
| form   | this argument is included to make the method function compatible with the generic and is ignored in this method.                                |
| level  | an optional integer vector giving the level(s) of grouping to be extracted from object. Defaults to the highest or innermost level of grouping. |
| data   | unused                                                                                                                                          |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .                      |

**Value**

either a data frame with columns given by the grouping factors indicated in `level`, or, when a single level is requested, a factor representing the selected grouping factor.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
fm1 <- lme(pixel ~ day + day^2, Pixel,
 random = list(Dog = ~day, Side = ~1))
getGroups(fm1, level = 1:2)
```

---

|                  |                                     |
|------------------|-------------------------------------|
| getGroups.lmList | <i>Extract lmList Object Groups</i> |
|------------------|-------------------------------------|

---

**Description**

The grouping factor determining the partitioning of the observations used to produce the `lm` components of object is extracted.

**Usage**

```
S3 method for class 'lmList'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.                                                                                                                    |
| form   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . Not used.                                                   |
| level  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used. |
| data   | a data frame in which to interpret the variables named in <code>form</code> . Optional for most methods. Not used.                                                                                                                           |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> . Not used.                                                                                                         |

**Value**

a vector with the grouping factor corresponding to the `lm` components of `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|--------------------------------|-------------------------------|
| <code>getGroups.varFunc</code> | <i>Extract varFunc Groups</i> |
|--------------------------------|-------------------------------|

---

**Description**

This method function extracts the grouping factor associated with the variance function represented by `object`, if any is present.

**Usage**

```
S3 method for class 'varFunc'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class varFunc, representing a variance function structure.                                                                                                                                                         |
| form   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the   operator). Defaults to formula(object). Not used.                                                                              |
| level  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used. |
| data   | a data frame in which to interpret the variables named in form. Optional for most methods. Not used.                                                                                                                                         |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/'. Not used.                                                                                                                       |

**Value**

if object has a groups attribute, its value is returned; else NULL is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
getGroups(vf1)
```

---

|                  |                                 |
|------------------|---------------------------------|
| getGroupsFormula | <i>Extract Grouping Formula</i> |
|------------------|---------------------------------|

---

**Description**

The conditioning expression associated with formula(object) (i.e. the expression after the | operator) is returned either as a named list of one-sided formulas, or a single one-sided formula, depending on the value of asList. The components of the returned list are ordered from outermost to innermost level and are named after the grouping factor expression.

**Usage**

```
getGroupsFormula(object, asList, sep)
```

**Arguments**

|        |                                                                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | any object from which a formula can be extracted.                                                                                                                   |
| asList | an optional logical value. If TRUE the returned value will be a list of formulas; else, if FALSE the returned value will be a one-sided formula. Defaults to FALSE. |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.                                                        |

**Value**

a one-sided formula, or a list of one-sided formulas, with the grouping structure associated with `formula(object)`. If no conditioning expression is present in `formula(object)` a NULL value is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|-------------|-------------------------------------------------|
| getResponse | <i>Extract Response Variable from an Object</i> |
|-------------|-------------------------------------------------|

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `data.frame`, `gl`, `lme`, and `lmList`.

**Usage**

```
getResponse(object, form)
```

**Arguments**

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| <code>object</code> | any object.                                                               |
| <code>form</code>   | an optional two-sided formula. Defaults to <code>formula(object)</code> . |

**Value**

For the `data.frame` method, the result of evaluating the left-hand side of `form` in `object`.  
 For `gl`, `lme`, and `lmList`, the sum of the fitted values and the residuals.

|-----------|-------------------------------------------|
| getVarCov | <i>Extract variance-covariance matrix</i> |
|-----------|-------------------------------------------|

---

**Description**

Extract the variance-covariance matrix from a fitted model, such as a mixed-effects model.

**Usage**

```
getVarCov(obj, ...)
S3 method for class 'lme'
getVarCov(obj, individuals,
 type = c("random.effects", "conditional", "marginal"), ...)
S3 method for class 'gls'
getVarCov(obj, individual = 1, ...)
```

Arguments

|             |                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| obj         | A fitted model. Methods are available for models fit by <a href="#">lme</a> and by <a href="#">gls</a>                                                                                                                                                                                                                                          |
| individuals | For models fit by <a href="#">lme</a> a vector of levels of the grouping factor can be specified for the conditional or marginal variance-covariance matrices.                                                                                                                                                                                  |
| individual  | For models fit by <a href="#">gls</a> the only type of variance-covariance matrix provided is the marginal variance-covariance of the responses by group. The optional argument individual specifies the group of responses.                                                                                                                    |
| type        | For models fit by <a href="#">lme</a> the type argument specifies the type of variance-covariance matrix, either "random.effects" for the random-effects variance-covariance (the default), or "conditional" for the conditional. variance-covariance of the responses or "marginal" for the the marginal variance-covariance of the responses. |
| ...         | Optional arguments for some methods, as described above                                                                                                                                                                                                                                                                                         |

Value

A variance-covariance matrix or a list of variance-covariance matrices.

|-----|---------------------------------------------------------|
| gls | <i>Fit Linear Model Using Generalized Least Squares</i> |
|-----|---------------------------------------------------------|

---

Description

This function fits a linear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

Usage

```
gls(model, data, correlation, weights, subset, method, na.action,
 control, verbose)
S3 method for class 'gls'
update(object, model., ..., evaluate = TRUE)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>      | an object inheriting from class "gls", representing a generalized least squares fitted linear model.                                                                                                                                                                                                                                                                                                                                           |
| <code>model</code>       | a two-sided linear formula object describing the model, with the response on the left of a <code>~</code> operator and the terms, separated by <code>+</code> operators, on the right.                                                                                                                                                                                                                                                         |
| <code>model.</code>      | Changes to the model – see <a href="#">update.formula</a> for details.                                                                                                                                                                                                                                                                                                                                                                         |
| <code>data</code>        | an optional data frame containing the variables named in <code>model</code> , <code>correlation</code> , <code>weights</code> , and <code>subset</code> . By default the variables are taken from the environment from which <code>gls</code> is called.                                                                                                                                                                                       |
| <code>correlation</code> | an optional <a href="#">corStruct</a> object describing the within-group correlation structure. See the documentation of <a href="#">corClasses</a> for a description of the available <code>corStruct</code> classes. If a grouping variable is to be used, it must be specified in the <code>form</code> argument to the <code>corStruct</code> constructor. Defaults to <code>NULL</code> , corresponding to uncorrelated errors.           |
| <code>weights</code>     | an optional <a href="#">varFunc</a> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <a href="#">varFixed</a> , corresponding to fixed variance weights. See the documentation on <a href="#">varClasses</a> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic errors. |
| <code>subset</code>      | an optional expression indicating which subset of the rows of <code>data</code> should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                         |
| <code>method</code>      | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".                                                                                                                                                                                                                                                                                       |
| <code>na.action</code>   | a function that indicates what should happen when the data contain NAs. The default action ( <a href="#">na.fail</a> ) causes <code>gls</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                               |
| <code>control</code>     | a list of control values for the estimation algorithm to replace the default values returned by the function <a href="#">glsControl</a> . Defaults to an empty list.                                                                                                                                                                                                                                                                           |
| <code>verbose</code>     | an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .                                                                                                                                                                                                                                                                                            |
| <code>...</code>         | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                      |
| <code>evaluate</code>    | If <code>TRUE</code> evaluate the new call else return the call.                                                                                                                                                                                                                                                                                                                                                                               |

**Details**

[offset](#) terms in `model` are an error since 3.1-157 (2022-03): previously they were silently ignored.

**Value**

an object of class "gls" representing the linear model fit. Generic functions such as `print`, `plot`, and `summary` have methods to show the results of the fit. See [glsObject](#) for the components of the fit. The functions [resid](#), [coef](#) and [fitted](#), can be used to extract some of its components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

The different correlation structures available for the `correlation` argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littell, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear models is presented in detail in Carroll, R.J. and Ruppert, D. (1988) and Davidian, M. and Giltinan, D.M. (1995).

## Examples

```
AR(1) errors within each Mare
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
 correlation = corAR1(form = ~ 1 | Mare))
variance increases as a power of the absolute fitted values
fm2 <- update(fm1, weights = varPower())
```

---

`glsControl`

*Control Values for gls Fit*

---

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `gls` function.

## Usage

```
glsControl(maxIter, msMaxIter, tolerance, msTol, msVerbose,
 singular.ok, returnObject = FALSE, apVar, .relStep,
 opt = c("nlminb", "optim"), optimMethod,
 minAbsParApVar, natural, sigma = NULL)
```

**Arguments**

|                |                                                                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maxIter        | maximum number of iterations for the gls optimization algorithm. Default is 50.                                                                                                    |
| msMaxIter      | maximum number of iterations for the optimization step inside the gls optimization. Default is 50.                                                                                 |
| tolerance      | tolerance for the convergence criterion in the gls algorithm. Default is 1e-6.                                                                                                     |
| msTol          | tolerance for the convergence criterion of the first outer iteration when optim is used. Default is 1e-7.                                                                          |
| msVerbose      | a logical value passed as the trace control value to the chosen optimizer (see documentation on that function). Default is FALSE.                                                  |
| singular.ok    | a logical value indicating whether non-estimable coefficients (resulting from linear dependencies among the columns of the regression matrix) should be allowed. Default is FALSE. |
| returnObject   | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.   |
| apVar          | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.                                  |
| .relStep       | relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .                                                                         |
| opt            | the optimizer to be used, either <code>"nlsminb"</code> (the current default) or <code>"optim"</code> (the previous default).                                                      |
| optimMethod    | character - the optimization method to be used with the <code>optim</code> optimizer. The default is <code>"BFGS"</code> . An alternative is <code>"L-BFGS-B"</code> .             |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is <code>0.05</code> .                                                       |
| natural        | logical. Should the natural parameterization be used for the approximate variance calculations? Default is TRUE.                                                                   |
| sigma          | optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.                                                                       |

**Value**

a list with components for each of the possible arguments.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

**Examples**

```
decrease the maximum number of iterations and request tracing
glsControl(msMaxIter = 20, msVerbose = TRUE)
```

glsObject

*Fitted gls Object***Description**

An object returned by the [gls](#) function, inheriting from class "gls" and representing a generalized least squares fitted linear model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate "gls" object.

|                           |                                                                                                                                                                                                                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>apVar</code>        | an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>gls</code> , this component is equal to <code>NULL</code> .                                                                        |
| <code>call</code>         | a list containing an image of the <code>gls</code> call that produced the object.                                                                                                                                                                                                                   |
| <code>coefficients</code> | a vector with the estimated linear model coefficients.                                                                                                                                                                                                                                              |
| <code>contrasts</code>    | a list of the contrast matrices used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list. |
| <code>dims</code>         | a list with basic dimensions used in the model fit, including the components <code>N</code> - the number of observations in the data and <code>p</code> - the number of coefficients in the linear model.                                                                                           |
| <code>fitted</code>       | a vector with the fitted values.                                                                                                                                                                                                                                                                    |
| <code>modelStruct</code>  | an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.                                                                                                                           |
| <code>groups</code>       | the correlation structure grouping factor, if any is present.                                                                                                                                                                                                                                       |
| <code>logLik</code>       | the log-likelihood at convergence.                                                                                                                                                                                                                                                                  |
| <code>method</code>       | the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.                                                                                                                                                                                             |
| <code>numIter</code>      | the number of iterations used in the iterative algorithm.                                                                                                                                                                                                                                           |
| <code>residuals</code>    | a vector with the residuals.                                                                                                                                                                                                                                                                        |
| <code>sigma</code>        | the estimated residual standard error.                                                                                                                                                                                                                                                              |
| <code>varBeta</code>      | an approximate covariance matrix of the coefficients estimates.                                                                                                                                                                                                                                     |

glsStruct

*Generalized Least Squares Structure***Description**

A generalized least squares structure is a list of model components representing different sets of parameters in the linear model. A glsStruct may contain corStruct and varFunc objects. NULL arguments are not included in the glsStruct list.

**Usage**

```
glsStruct(corStruct, varStruct)
```

**Arguments**

**corStruct** an optional corStruct object, representing a correlation structure. Default is NULL.

**varStruct** an optional varFunc object, representing a variance function structure. Default is NULL.

**Value**

a list of model variance-covariance components determining the parameters to be estimated for the associated linear model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[corClasses](#), [gls](#), [residuals.glsStruct](#), [varFunc](#)

**Examples**

```
gls1 <- glsStruct(corAR1(), varPower())
```

Glucose

*Glucose levels over time***Description**

The Glucose data frame has 378 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** an ordered factor with levels 6 < 2 < 3 < 5 < 1 < 4

**Time** a numeric vector

**conc** a numeric vector of glucose levels

**Meal** an ordered factor with levels 2am < 6am < 10am < 2pm < 6pm < 10pm

**Source**

Hand, D. and Crowder, M. (1996), *Practical Longitudinal Data Analysis*, Chapman and Hall, London.

---

Glucose2

*Glucose Levels Following Alcohol Ingestion*

---

**Description**

The Glucose2 data frame has 196 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** a factor with levels 1 to 7 identifying the subject whose glucose level is measured.

**Date** a factor with levels 1 2 indicating the occasion in which the experiment was conducted.

**Time** a numeric vector giving the time since alcohol ingestion (in min/10).

**glucose** a numeric vector giving the blood glucose level (in mg/dl).

**Details**

Hand and Crowder (Table A.14, pp. 180-181, 1996) describe data on the blood glucose levels measured at 14 time points over 5 hours for 7 volunteers who took alcohol at time 0. The same experiment was repeated on a second date with the same subjects but with a dietary additive used for all subjects.

gnls

*Fit Nonlinear Model Using Generalized Least Squares*

---

**Description**

This function fits a nonlinear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
gnls(model, data, params, start, correlation, weights, subset,
 na.action, naPattern, control, verbose)
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| model       | a two-sided formula object describing the model, with the response on the left of a <code>~</code> operator and a nonlinear expression involving parameters and covariates on the right. If data is given, all names used in the formula should be defined as parameters or variables in the data frame.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| data        | an optional data frame containing the variables named in model, correlation, weights, subset, and naPattern. By default the variables are taken from the environment from which gnls is called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| params      | an optional two-sided linear formula of the form $p_1 + \dots + p_n \sim x_1 + \dots + x_m$ , or list of two-sided formulas of the form $p_1 \sim x_1 + \dots + x_m$ , with possibly different models for each parameter. The $p_1, \dots, p_n$ represent parameters included on the right hand side of model and $x_1 + \dots + x_m$ define a linear model for the parameters (when the left hand side of the formula contains several parameters, they are all assumed to follow the same linear model described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s). By default, the parameters are obtained from the names of start. |
| start       | an optional named list, or numeric vector, with the initial values for the parameters in model. It can be omitted when a "selfStart" model is used, in which case the starting estimates will be obtained from a single call to the nls function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| correlation | an optional corStruct object describing the within-group correlation structure. See the documentation of <a href="#">corClasses</a> for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors.                                                                                                                                                                                                                                                                                                                                                                           |
| weights     | an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on <a href="#">varClasses</a> for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic errors.                                                                                                                                                                                                                                                                                                                                                        |
| subset      | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| na.action   | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes gnls to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| naPattern   | an expression or formula object, specifying which returned values are to be regarded as missing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| control     | a list of control values for the estimation algorithm to replace the default values returned by the function gnlsControl. Defaults to an empty list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| verbose     | an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Value**

an object of class gnls, also inheriting from class gls, representing the nonlinear model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See gnlsObject for the components of the fit. The functions resid, coef, and fitted can be used to extract some of its components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

The different correlation structures available for the `correlation` argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littell, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear models is presented in detail in Carrol, R.J. and Rupert, D. (1988) and Davidian, M. and Giltinan, D.M. (1995).

gnlsControl

*Control Values for gnls Fit*

---

**Description**

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the `gnls` function.

**Usage**

```
gnlsControl(maxIter = 50, nlsMaxIter = 7, msMaxIter = 50, minScale = 0.001,
 tolerance = 1e-6, nlsTol = 0.001, msTol = 1e-7,
 returnObject = FALSE, msVerbose = FALSE,
 apVar = TRUE, .relStep =,
 opt = c("nlsminb", "optim"), optimMethod = "BFGS",
 minAbsParApVar = 0.05, sigma = NULL)
```

**Arguments**

|                |                                                                                                                                                                                                                                                 |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maxIter        | maximum number of iterations for the gnls optimization algorithm. Default is 50.                                                                                                                                                                |
| nlsMaxIter     | maximum number of iterations for the nls optimization step <i>inside</i> the gnls optimization. Default is 7.                                                                                                                                   |
| msMaxIter      | maximum number of iterations for the optimization step inside the gnls optimization. Default is 50.                                                                                                                                             |
| minScale       | minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the nls step. Default 0.001.                                                                                                            |
| tolerance      | tolerance for the convergence criterion in the gnls algorithm. Default is 1e-6.                                                                                                                                                                 |
| nlsTol         | tolerance for the convergence criterion in nls step. Default is 1e-3.                                                                                                                                                                           |
| msTol          | tolerance for the convergence criterion of the first outer iteration when optim is used. Default is 1e-7.                                                                                                                                       |
| returnObject   | a logical value indicating whether the fitted object should be returned with a <a href="#">warning</a> (instead of an error via <a href="#">stop()</a> ) when the maximum number of iterations is reached without convergence of the algorithm. |
| msVerbose      | a logical value passed as the trace argument to the optimizer chosen by opt; see documentation on that. Default is FALSE.                                                                                                                       |
| apVar          | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.                                                                                               |
| .relStep       | relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> (about 6e-6).                                                                                                                          |
| opt            | the optimizer to be used, either " <a href="#">nlminb</a> " (the current default) or " <a href="#">optim</a> " (the previous default).                                                                                                          |
| optimMethod    | character - the optimization method to be used with the <a href="#">optim</a> optimizer. The default is "BFGS". An alternative is "L-BFGS-B".                                                                                                   |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.                                                                                                                                  |
| sigma          | optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.                                                                                                                                    |

**Value**

a list with components for each of the possible arguments.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

**See Also**

**Examples**

```
decrease the maximum number of iterations and request tracing
gnlsControl(msMaxIter = 20, msVerbose = TRUE)
```

gnlsObject

*Fitted gnls Object***Description**

An object returned by the `gnls` function, inheriting from class "gnls" and also from class "gls", and representing a generalized nonlinear least squares fitted model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate "gnls" object.

|                           |                                                                                                                                                                                                                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>apVar</code>        | an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the control values used in the call to <code>gnls</code> , this component is equal to <code>NULL</code> .                                                                               |
| <code>call</code>         | a list containing an image of the <code>gnls</code> call that produced the object.                                                                                                                                                                                                                  |
| <code>coefficients</code> | a vector with the estimated nonlinear model coefficients.                                                                                                                                                                                                                                           |
| <code>contrasts</code>    | a list of the contrast matrices used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list. |
| <code>dims</code>         | a list with basic dimensions used in the model fit, including the components <code>N</code> - the number of observations used in the fit and <code>p</code> - the number of coefficients in the nonlinear model.                                                                                    |
| <code>fitted</code>       | a vector with the fitted values.                                                                                                                                                                                                                                                                    |
| <code>modelStruct</code>  | an object inheriting from class <code>gnlsStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects.                                                                                                                                 |
| <code>groups</code>       | a vector with the correlation structure grouping factor, if any is present.                                                                                                                                                                                                                         |
| <code>logLik</code>       | the log-likelihood at convergence.                                                                                                                                                                                                                                                                  |
| <code>numIter</code>      | the number of iterations used in the iterative algorithm.                                                                                                                                                                                                                                           |
| <code>plist</code>        |                                                                                                                                                                                                                                                                                                     |
| <code>pmap</code>         |                                                                                                                                                                                                                                                                                                     |
| <code>residuals</code>    | a vector with the residuals.                                                                                                                                                                                                                                                                        |
| <code>sigma</code>        | the estimated residual standard error.                                                                                                                                                                                                                                                              |
| <code>varBeta</code>      | an approximate covariance matrix of the coefficients estimates.                                                                                                                                                                                                                                     |

gnlsStruct

*Generalized Nonlinear Least Squares Structure***Description**

A generalized nonlinear least squares structure is a list of model components representing different sets of parameters in the nonlinear model. A `gnlsStruct` may contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `gnlsStruct` list.

**Usage**

```
gnlsStruct(corStruct, varStruct)
```

**Arguments**

|                        |                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------|
| <code>corStruct</code> | an optional <code>corStruct</code> object, representing a correlation structure. Default is NULL.     |
| <code>varStruct</code> | an optional <code>varFunc</code> object, representing a variance function structure. Default is NULL. |

**Value**

a list of model variance-covariance components determining the parameters to be estimated for the associated nonlinear model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
gnls1 <- gnlsStruct(corAR1(), varPower())
```

groupedData

*Construct a groupedData Object***Description**

An object of the `groupedData` class is constructed from the formula and data by attaching the formula as an attribute of the data, along with any of `outer`, `inner`, `labels`, and `units` that are given. If `order.groups` is `TRUE` the grouping factor is converted to an ordered factor with the ordering determined by `FUN`. Depending on the number of grouping levels and the type of primary covariate, the returned object will be of one of three classes: `nfnGroupedData` - numeric covariate, single level of nesting; `nffGroupedData` - factor covariate, single level of nesting; and `nmGroupedData` - multiple levels of nesting. Several modeling and plotting functions can use the formula stored with a `groupedData` object to construct default plots and models.

**Usage**

```
groupedData(formula, data, order.groups, FUN, outer, inner,
 labels, units)
```

```
S3 method for class 'groupedData'
update(object, formula, data, order.groups, FUN,
 outer, inner, labels, units, ...)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>       | an object inheriting from class <code>groupedData</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>formula</code>      | a formula of the form <code>resp ~ cov   group</code> where <code>resp</code> is the response, <code>cov</code> is the primary covariate, and <code>group</code> is the grouping factor. The expression 1 can be used for the primary covariate when there is no other suitable candidate. Multiple nested grouping factors can be listed separated by the <code>/</code> symbol as in <code>fact1/fact2</code> . In an expression like this the <code>fact2</code> factor is nested within the <code>fact1</code> factor.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>data</code>         | a data frame in which the expressions in <code>formula</code> can be evaluated. The resulting <code>groupedData</code> object will consist of the same data values in the same order but with additional attributes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>order.groups</code> | an optional logical value, or list of logical values, indicating if the grouping factors should be converted to ordered factors according to the function <code>FUN</code> applied to the response from each group. If multiple levels of grouping are present, this argument can be either a single logical value (which will be repeated for all grouping levels) or a list of logical values. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). Ordering within a level of grouping is done within the levels of the grouping factors which are outer to it. Changing the grouping factor to an ordered factor does not affect the ordering of the rows in the data frame but it does affect the order of the panels in a trellis display of the data or models fitted to the data. Defaults to <code>TRUE</code> .                               |
| <code>FUN</code>          | an optional summary function that will be applied to the values of the response for each level of the grouping factor, when <code>order.groups = TRUE</code> , to determine the ordering. Defaults to the <code>max</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>outer</code>        | an optional one-sided formula, or list of one-sided formulas, indicating covariates that are outer to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. When plotting a <code>groupedData</code> object, the argument <code>outer = TRUE</code> causes the panels to be determined by the outer formula. The points within the panels are associated by level of the grouping factor. Defaults to <code>NULL</code> , meaning that no outer covariates are present. |
| <code>inner</code>        | an optional one-sided formula, or list of one-sided formulas, indicating covariates that are inner to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An inner covariate can change within the sets of rows defined by the grouping factor.                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|        |                                                                                                                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | An inner formula can be used to associate points in a plot of a groupedData object. Defaults to NULL, meaning that no inner covariates are present.                                                                                |
| labels | an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named x and that for the response is named y. Either label can be omitted.                  |
| units  | an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named x and that for the response is named y. Either units string can be omitted. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                          |

### Value

an object of one of the classes `nfnGroupedData`, `nffGroupedData`, or `nmGroupedData`, and also inheriting from classes `groupedData` and `data.frame`.

gsummary(Orth.new) # apply summary by Subject
fm1 <- lme(Orth.new) # fixed and groups formulae extracted from object
Orthodont2 <- update(Orthodont, FUN = mean)
```

gsummary

*Summarize by Groups***Description**

Provide a summary of the variables in a data frame by groups of rows. This is most useful with a `groupedData` object to examine the variables by group.

**Usage**

```
gsummary(object, FUN, omitGroupingFactor, form, level,
 groups, invariantsOnly, ...)
```

**Arguments**

- |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object             | an object to be summarized - usually a <code>groupedData</code> object or a <code>data.frame</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| FUN                | an optional summary function or a list of summary functions to be applied to each variable in the frame. The function or functions are applied only to variables in object that vary within the groups defined by groups. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| omitGroupingFactor | an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary but the levels of the grouping factor will continue to be used as the row names for the data frame that is produced by the summary. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| form               | an optional one-sided formula that defines the groups. When this formula is given, the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to <code>formula(object)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| level              | an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| groups             | an optional factor that will be used to split the rows into groups. Defaults to <code>getGroups(object, form, level)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| invariantsOnly     | an optional logical value. When <code>TRUE</code> only those covariates that are invariant within each group will be summarized. The summary value for the group is always the unique value taken on by that covariate within the group. The columns in the summary are of the same class as the corresponding columns in object. By definition, the grouping factor itself must be an invariant. When combined with <code>omitGroupingFactor = TRUE</code> , this option can be used to discover if there are invariant covariates in the data frame. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

... optional additional arguments to the summary functions that are invoked on the variables by group. Often it is helpful to specify `na.rm = TRUE`.

### Value

A data.frame with one row for each level of the grouping factor. The number of columns is at most the number of columns in object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

### Examples

```
gsummary(Orthodont) # default summary by Subject
gsummary with invariantsOnly = TRUE and omitGroupingFactor = TRUE
determines whether there are covariates like Sex that are invariant
within the repeated observations on the same Subject.
gsummary(Orthodont, invariantsOnly = TRUE, omitGroupingFactor = TRUE)
```

---

Gun

*Methods for firing naval guns*

---

### Description

The Gun data frame has 36 rows and 4 columns.

### Format

This data frame contains the following columns:

**rounds** a numeric vector

**Method** a factor with levels M1 M2

**Team** an ordered factor with levels T1S < T3S < T2S < T1A < T2A < T3A < T1H < T3H < T2H

**Physique** an ordered factor with levels Slight < Average < Heavy

### Details

Hicks (p.180, 1993) reports data from an experiment on methods for firing naval guns. Gunners of three different physiques (slight, average, and heavy) tested two firing methods. Both methods were tested twice by each of nine teams of three gunners with identical physique. The response was the number of rounds fired per minute.

|-----|------------------------------------------|
| IGF | <i>Radioimmunoassay of IGF-I Protein</i> |
|-----|------------------------------------------|

---

Description

The IGF data frame has 237 rows and 3 columns.

Format

This data frame contains the following columns:

- Lot** an ordered factor giving the radioactive tracer lot.
- age** a numeric vector giving the age (in days) of the radioactive tracer.
- conc** a numeric vector giving the estimated concentration of IGF-I protein (ng/ml)

Details

Davidian and Giltinan (1995) describe data obtained during quality control radioimmunoassays for ten different lots of radioactive tracer used to calibrate the Insulin-like Growth Factor (IGF-I) protein concentration measurements.

|------------|--------------------------|
| Initialize | <i>Initialize Object</i> |
|------------|--------------------------|

---

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, glsStruct, lmeStruct, reStruct, and varFunc.

Usage

Initialize(object, data, ...)

**Arguments**

|        |                                                                                                       |
|--------|-------------------------------------------------------------------------------------------------------|
| object | any object requiring initialization, e.g. "plug-in" structures such as corStruct and varFunc objects. |
| data   | a data frame to be used in the initialization procedure.                                              |
| ...    | some methods for this generic function require additional arguments.                                  |

**Value**

an initialized object with the same class as object. Changes introduced by the initialization procedure will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

`Initialize.corStruct`    *Initialize corStruct Object*

---

**Description**

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data, calculating various dimensions and constants used by optimization algorithms involving corStruct objects (see the appropriate Dim method documentation), and assigning initial values for the coefficients in object, if none were present.

**Usage**

```
S3 method for class 'corStruct'
Initialize(object, data, ...)
```

**Arguments**

|        |                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">corStruct</a> " representing a correlation structure. |
| data   | a data frame in which to evaluate the variables defined in formula(object).                         |
| ...    | this argument is included to make this method compatible with the generic.                          |

**Value**

an initialized object with the same class as object representing a correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

cs1 <- Initialize(cs1, data = Orthodont)
```

---

Initialize.glsStruct    *Initialize a glsStruct Object*

---

**Description**

The individual linear model components of the glsStruct list are initialized.

**Usage**

```
S3 method for class 'glsStruct'
Initialize(object, data, control, ...)
```

**Arguments**

|         |                                                                                                                                                                                                                 |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | an object inheriting from class " <a href="#">glsStruct</a> ", representing a list of linear model components, such as corStruct and varFunc objects.                                                           |
| data    | a data frame in which to evaluate the variables defined in formula(object).                                                                                                                                     |
| control | an optional list with control parameters for the initialization and optimization algorithms used in gls. Defaults to list(singular.ok = FALSE), implying that linear dependencies are not allowed in the model. |
| ...     | some methods for this generic require additional arguments. None are used in this method.                                                                                                                       |

**Value**

a glsStruct object similar to object, but with initialized model components.

Initialize.lmeStruct    *Initialize an lmeStruct Object*

---

## Description

The individual linear mixed-effects model components of the lmeStruct list are initialized.

## Usage

```
S3 method for class 'lmeStruct'
Initialize(object, data, groups, conLin, control, ...)
```

## Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | an object inheriting from class " <a href="#">lmeStruct</a> ", representing a list of linear mixed-effects model components, such as reStruct, corStruct, and varFunc objects.                                                                                                                                                                                                                                                                      |
| data    | a data frame in which to evaluate the variables defined in formula(object).                                                                                                                                                                                                                                                                                                                                                                         |
| groups  | a data frame with the grouping factors corresponding to the lme model associated with object as columns, sorted from innermost to outermost grouping level.                                                                                                                                                                                                                                                                                         |
| conLin  | an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to attr(object, "conLin").                                                                                                                                                              |
| control | an optional list with control parameters for the initialization and optimization algorithms used in lme. Defaults to list(niterEM=20, gradHess=TRUE), implying that 20 EM iterations are to be used in the derivation of initial estimates for the coefficients of the reStruct component of object and, if possible, numerical gradient vectors and Hessian matrices for the log-likelihood function are to be used in the optimization algorithm. |
| ...     | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                           |

## Value

an lmeStruct object similar to object, but with initialized model components.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[lme](#), [Initialize.reStruct](#), [Initialize.corStruct](#), [Initialize.varFunc](#), [Initialize](#)

---

Initialize.reStruct     *Initialize reStruct Object*

---

## Description

Initial estimates for the parameters in the pdMat objects forming object, which have not yet been initialized, are obtained using the methodology described in Bates and Pinheiro (1998). These estimates may be refined using a series of EM iterations, as described in Bates and Pinheiro (1998). The number of EM iterations to be used is defined in control.

## Usage

```
S3 method for class 'reStruct'
Initialize(object, data, conLin, control, ...)
```

## Arguments

|         |                                                                                                                                                                                                                                                               |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of pdMat objects.                                                                                                              |
| data    | a data frame in which to evaluate the variables defined in formula(object).                                                                                                                                                                                   |
| conLin  | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.                          |
| control | an optional list with a single component niterEM controlling the number of iterations for the EM algorithm used to refine initial parameter estimates. It is given as a list for compatibility with other Initialize methods. Defaults to list(niterEM = 20). |
| ...     | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                     |

## Value

an reStruct object similar to object, but with all pdMat components initialized.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

|                    |                                  |
|--------------------|----------------------------------|
| Initialize.varFunc | <i>Initialize varFunc Object</i> |
|--------------------|----------------------------------|

---

## Description

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data; determining if the covariate(s) need to be updated when the values of the coefficients associated with object change; initializing the log-likelihood and the weights associated with object; and assigning initial values for the coefficients in object, if none were present. The covariate(s) will only be initialized if no update is needed when `coef(object)` changes.

## Usage

```
S3 method for class 'varFunc'
Initialize(object, data, ...)
```

## Arguments

|        |                                                                                                       |
|--------|-------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <code>varFunc</code> ", representing a variance function structure. |
| data   | a data frame in which to evaluate the variables named in <code>formula(object)</code> .               |
| ...    | this argument is included to make this method compatible with the generic.                            |

## Value

an initialized object with the same class as object representing a variance function structure.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

## Examples

```
vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
```

intervals

*Confidence Intervals on Coefficients***Description**

Confidence intervals on the parameters associated with the model represented by object are obtained. This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

**Usage**

```
intervals(object, level, ...)
```

**Arguments**

|        |                                                                                |
|--------|--------------------------------------------------------------------------------|
| object | a fitted model object from which parameter estimates can be extracted.         |
| level  | an optional numeric value for the interval confidence level. Defaults to 0.95. |
| ...    | some methods for the generic may require additional arguments.                 |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

intervals.gls

*Confidence Intervals on gls Parameters***Description**

Approximate confidence intervals for the parameters in the linear model represented by object are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale.

**Usage**

```
S3 method for class 'glS'
intervals(object, level, which, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">glS</a> ", representing a generalized least squares fitted linear model.                                                                                                                                                                       |
| level  | an optional numeric value for the interval confidence level. Defaults to 0.95.                                                                                                                                                                                                               |
| which  | an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "coef" for the linear model coefficients only. Defaults to "all". |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                    |

**Value**

a list with components given by data frames with rows corresponding to parameters and columns lower, est., and upper representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

|           |                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------|
| coef      | linear model coefficients, only present when which is not equal to "var-cov".                                                     |
| corStruct | correlation parameters, only present when which is not equal to "coef" and a correlation structure is used in object.             |
| varFunc   | variance function parameters, only present when which is not equal to "coef" and a variance function structure is used in object. |
| sigma     | residual standard error.                                                                                                          |

intervals.lme

*Confidence Intervals on lme Parameters***Description**

Approximate confidence intervals for the parameters in the linear mixed-effects model represented by object are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale. The pdNatural parametrization is used for general positive-definite matrices.

**Usage**

```
S3 method for class 'lme'
intervals(object, level = 0.95,
 which = c("all", "var-cov", "fixed"), ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                        |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>"lme"</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                 |
| level  | an optional numeric value with the confidence level for the intervals. Defaults to 0.95.                                                                                                                                                                                                                                               |
| which  | an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are <code>"all"</code> for all parameters, <code>"var-cov"</code> for the variance-covariance parameters only, and <code>"fixed"</code> for the fixed effects only. Defaults to <code>"all"</code> . |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                              |

**Value**

a list with components given by data frames with rows corresponding to parameters and columns lower, est., and upper representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

|           |                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fixed     | fixed effects, only present when which is not equal to <code>"var-cov"</code> .                                                                              |
| reStruct  | random effects variance-covariance parameters, only present when which is not equal to <code>"fixed"</code> .                                                |
| corStruct | within-group correlation parameters, only present when which is not equal to <code>"fixed"</code> and a correlation structure is used in object.             |
| varFunc   | within-group variance function parameters, only present when which is not equal to <code>"fixed"</code> and a variance function structure is used in object. |
| sigma     | within-group standard deviation.                                                                                                                             |

## Examples

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
intervals(fm1)
```

---

intervals.lmList

*Confidence Intervals on lmList Coefficients*

---

## Description

Confidence intervals on the linear model coefficients are obtained for each `lm` component of object and organized into a three dimensional array. The first dimension corresponding to the names of the object components. The second dimension is given by lower, est., and upper corresponding, respectively, to the lower confidence limit, estimated coefficient, and upper confidence limit. The third dimension is given by the coefficients names.

## Usage

```
S3 method for class 'lmList'
intervals(object, level = 0.95, pool = attr(object, "pool"), ...)
```

## Arguments

|        |                                                                                                                                                              |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <code>lmList</code> ", representing a list of <code>lm</code> objects with a common model.                                 |
| level  | an optional numeric value with the confidence level for the intervals. Defaults to 0.95.                                                                     |
| pool   | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> . |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                    |

## Value

a three dimensional array with the confidence intervals and estimates for the coefficients of each `lm` component of object.

|            |                                   |
|------------|-----------------------------------|
| isBalanced | <i>Check a Design for Balance</i> |
|------------|-----------------------------------|

---

Description

Check the design of the experiment or study for balance.

Usage

```
isBalanced(object, countOnly, level)
```

Arguments

|           |                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | A groupedData object containing a data frame and a formula that describes the roles of variables in the data frame. The object will have one or more nested grouping factors and a primary covariate.                             |
| countOnly | A logical value indicating if the check for balance should only consider the number of observations at each level of the grouping factor(s). Defaults to FALSE.                                                                   |
| level     | an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level. |

Details

A design is balanced with respect to the grouping factor(s) if there are the same number of observations at each distinct value of the grouping factor or each combination of distinct levels of the nested grouping factors. If countOnly is FALSE the design is also checked for balance with respect to the primary covariate, which is often the time of the observation. A design is balanced with respect to the grouping factor and the covariate if the number of observations at each distinct level (or combination of levels for nested factors) is constant and the times at which the observations are taken (in general, the values of the primary covariates) also are constant.

Value

TRUE or FALSE according to whether the data are balanced or not

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|---------------|---------------------------------------|
| isInitialized | <i>Check if Object is Initialized</i> |
|---------------|---------------------------------------|

---

**Description**

Checks if object has been initialized (generally through a call to `Initialize`), by searching for components and attributes which are modified during initialization.

**Usage**

```
isInitialized(object)
```

**Arguments**

|        |                                      |
|--------|--------------------------------------|
| object | any object requiring initialization. |
|--------|--------------------------------------|

**Value**

a logical value indicating whether object has been initialized.

**Author(s)**

José Pinheiro and Douglas Bates

**Examples**

```
pd1 <- pdDiag(~age)
isInitialized(pd1)
```

---

LDEsysMat

Generate system matrix for LDEs

---

### Description

Generate the system matrix for the linear differential equations determined by a compartment model.

### Usage

```
LDEsysMat(pars, incidence)
```

### Arguments

|           |                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pars      | a numeric vector of parameter values.                                                                                                                                                                                                                                          |
| incidence | an integer matrix with columns named From, To, and Par. Values in the Par column must be in the range 1 to length(pars). Values in the From column must be between 1 and the number of compartments. Values in the To column must be between 0 and the number of compartments. |

### Details

A compartment model describes material transfer between  $k$  in a system of  $k$  compartments to a linear system of differential equations. Given a description of the system and a vector of parameter values this function returns the system matrix.

This function is intended for use in a general system for solving compartment models, as described in Bates and Watts (1988).

### Value

A  $k$  by  $k$  numeric matrix.

### Author(s)

Douglas Bates <bates@stat.wisc.edu>

### References

### Examples

```
incidence matrix for a two compartment open system
incidence <-
 matrix(c(1,1,2,2,2,1,3,2,0), ncol = 3, byrow = TRUE,
 dimnames = list(NULL, c("Par", "From", "To")))
incidence
LDEsysMat(c(1.2, 0.3, 0.4), incidence)
```

lme

*Linear Mixed-Effects Models***Description**

This generic function fits a linear mixed-effects model in the formulation described in Laird and Ware (1982) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

This page describes the formula method; the methods [lme.lmList](#) and [lme.groupedData](#) are documented separately.

**Usage**

```
lme(fixed, data, random, correlation, weights, subset, method,
 na.action, control, contrasts = NULL, keep.data = TRUE)

S3 method for class 'formula'
lme(fixed, data, random, correlation, weights, subset, method,
 na.action, control, contrasts = NULL, keep.data = TRUE)

S3 method for class 'lme'
update(object, fixed., ..., evaluate = TRUE)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| fixed  | a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a <code>~</code> operator and the terms, separated by <code>+</code> operators, on the right, an <a href="#">"lmList"</a> object, or a <a href="#">"groupedData"</a> object.<br>There is limited support for formulae such as <code>resp ~ 1</code> and <code>resp ~ 0</code> , and less prior to version '3.1-112'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| fixed. | Changes to the fixed-effects formula – see <a href="#">update.formula</a> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| data   | an optional data frame containing the variables named in <code>fixed</code> , <code>random</code> , <code>correlation</code> , <code>weights</code> , and <code>subset</code> . By default the variables are taken from the environment from which <code>lme</code> is called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| random | optionally, any of the following: (i) a one-sided formula of the form <code>~ x1 + ... + xn   g1/.../gm</code> , with <code>x1 + ... + xn</code> specifying the model for the random effects and <code>g1/.../gm</code> the grouping structure ( <code>m</code> may be equal to 1, in which case no <code>/</code> is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form <code>~ x1 + ... + xn   g</code> , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form <code>~ x1 + ... + xn</code> , or a <a href="#">pdMat</a> object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or <a href="#">pdMat</a> objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class <a href="#">"groupedData"</a> ; (iv) a named list of formulas or <a href="#">pdMat</a> objects as in (iii), with the grouping factors |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an <a href="#">reStruct</a> object. See the documentation on <a href="#">pdClasses</a> for a description of the available <a href="#">pdMat</a> classes. Defaults to a formula consisting of the right hand side of fixed.                                                                                                                 |
| correlation | an optional <a href="#">corStruct</a> object describing the within-group correlation structure. See the documentation of <a href="#">corClasses</a> for a description of the available <a href="#">corStruct</a> classes. Defaults to NULL, corresponding to no within-group correlations.                                                                                                                                                       |
| weights     | an optional <a href="#">varFunc</a> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <a href="#">varFixed</a> , corresponding to fixed variance weights. See the documentation on <a href="#">varClasses</a> for a description of the available <a href="#">varFunc</a> classes. Defaults to NULL, corresponding to homoscedastic within-group errors. |
| subset      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                                     |
| method      | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".                                                                                                                                                                                                                                                                                         |
| na.action   | a function that indicates what should happen when the data contain NAs. The default action ( <a href="#">na.fail</a> ) causes lme to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                              |
| control     | a list of control values for the estimation algorithm to replace the default values returned by the function <a href="#">lmeControl</a> . Defaults to an empty list.                                                                                                                                                                                                                                                                             |
| contrasts   | an optional list. See the <code>contrasts.arg</code> of <a href="#">model.matrix.default</a> .                                                                                                                                                                                                                                                                                                                                                   |
| keep.data   | logical: should the data argument (if supplied and a data frame) be saved as part of the model object?                                                                                                                                                                                                                                                                                                                                           |
| ...         | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                        |
| evaluate    | If TRUE evaluate the new call else return the call.                                                                                                                                                                                                                                                                                                                                                                                              |

### Details

[offset](#) terms in fixed are an error since 3.1-157 (2022-03): previously they were silently ignored.

### Value

An object of class "lme" representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See [lmeObject](#) for the components of the fit. The functions [resid](#), [coef](#), [fitted](#), [fixed.effects](#), and [random.effects](#) can be used to extract some of its components.

### Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

The computational methods follow the general framework of Lindstrom and Bates (1988). The model formulation is described in Laird and Ware (1982). The variance-covariance parametrizations are described in Pinheiro and Bates (1996). The different correlation structures available for the correlation argument are described in Box, Jenkins and Reinsel (1994), Littell *et al* (1996), and Venables and Ripley (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian and Giltinan (1995).

## Examples

```
fm1 <- lme(distance ~ age, data = Orthodont) # random is ~ age
fm2 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
summary(fm1)
summary(fm2)
```

---

lme.groupedData

LME fit from groupedData Object

---

## Description

The response variable and primary covariate in formula(fixed) are used to construct the fixed effects model formula. This formula and the groupedData object are passed as the fixed and data arguments to lme. formula, together with any other additional arguments in the function call. See the documentation on [lme.formula](#) for a description of that function.

**Usage**

```
S3 method for class 'groupedData'
lme(fixed, data, random, correlation, weights,
 subset, method, na.action, control, contrasts, keep.data = TRUE)
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| fixed       | a data frame inheriting from class <code>"groupedData"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| data        | this argument is included for consistency with the generic function. It is ignored in this method function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| random      | optionally, any of the following: (i) a one-sided formula of the form $\sim x_1 + \dots + x_n \mid g_1 / \dots / g_m$ , with $x_1 + \dots + x_n$ specifying the model for the random effects and $g_1 / \dots / g_m$ the grouping structure ( $m$ may be equal to 1, in which case no $/$ is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form $\sim x_1 + \dots + x_n \mid g$ , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form $\sim x_1 + \dots + x_n$ , or a <code>pdMat</code> object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or <code>pdMat</code> objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class <code>groupedData</code> ; (iv) a named list of formulas or <code>pdMat</code> objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an <code>reStruct</code> object. See the documentation on <code>pdClasses</code> for a description of the available <code>pdMat</code> classes. Defaults to a formula consisting of the right hand side of <code>fixed</code> . |
| correlation | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <a href="#">corClasses</a> for a description of the available <code>corStruct</code> classes. Defaults to NULL, corresponding to no within-group correlations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| weights     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <a href="#">varClasses</a> for a description of the available <code>varFunc</code> classes. Defaults to NULL, corresponding to homoscedastic within-group errors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| subset      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| method      | a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"REML"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| na.action   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| control     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| contrasts   | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| keep.data   | logical: should the data argument (if supplied and a data frame) be saved as part of the model object?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Value**

an object of class `lme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

The computational methods follow on the general framework of Lindstrom, M.J. and Bates, D.M. (1988). The model formulation is described in Laird, N.M. and Ware, J.H. (1982). The variance-covariance parametrizations are described in Pinheiro, J.C. and Bates., D.M. (1996). The different correlation structures available for the `correlation` argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littell, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian, M. and Giltinan, D.M. (1995).

lme.lmList

*LME fit from lmList Object***Description**

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain fixed are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on [lme.formula](#) for a description of that function.

**Usage**

```
S3 method for class 'lmList'
lme(fixed, data, random, correlation, weights, subset, method,
 na.action, control, contrasts, keep.data)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fixed</code>       | an object inheriting from class " <a href="#">lmList</a> ", representing a list of <code>lm</code> fits with a common model.                                                                                                                                                                                                                                                                                                                          |
| <code>data</code>        | this argument is included for consistency with the generic function. It is ignored in this method function.                                                                                                                                                                                                                                                                                                                                           |
| <code>random</code>      | an optional one-sided linear formula with no conditioning expression, or a <code>pdMat</code> object with a <code>formula</code> attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of <code>formula(fixed)</code> .                                                                                                                                           |
| <code>correlation</code> | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <a href="#">corClasses</a> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.                                                                                                                                                    |
| <code>weights</code>     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <a href="#">varClasses</a> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors. |
| <code>subset</code>      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                                          |
| <code>method</code>      | a character string. If " <code>REML</code> " the model is fit by maximizing the restricted log-likelihood. If " <code>ML</code> " the log-likelihood is maximized. Defaults to " <code>REML</code> ".                                                                                                                                                                                                                                                 |
| <code>na.action</code>   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                         |
| <code>control</code>     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.                                                                                                                                                                                                                                                                                     |

|           |                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------|
| contrasts | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .            |
| keep.data | logical: should the data argument (if supplied and a data frame) be saved as part of the model object? |

### Value

an object of class `lme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

## lmeControl

*Specifying Control Values for lme Fit***Description**

The values supplied in the `lmeControl()` call replace the defaults, and a [list](#) with all settings (i.e., values for all possible arguments) is returned. The returned list is used as the control argument to the `lme` function.

**Usage**

```
lmeControl(maxIter = 50, msMaxIter = 50, tolerance = 1e-6, niterEM = 25,
 msMaxEval = 200,
 msTol = 1e-7, msVerbose = FALSE,
 returnObject = FALSE, gradHess = TRUE, apVar = TRUE,
 .relStep = .Machine$double.eps^(1/3), minAbsParApVar = 0.05,
 opt = c("nlminb", "optim"),
 optimMethod = "BFGS", natural = TRUE,
 sigma = NULL,
 allow.n.lt.q = FALSE,
 ...)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>maxIter</code>      | maximum number of iterations for the <code>lme</code> optimization algorithm. Default is 50.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>msMaxIter</code>    | maximum number of iterations for the optimization step inside the <code>lme</code> optimization. Default is 50.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>tolerance</code>    | tolerance for the convergence criterion in the <code>lme</code> algorithm. Default is 1e-6.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>niterEM</code>      | number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>msMaxEval</code>    | maximum number of evaluations of the objective function permitted for <a href="#">nlminb</a> . Default is 200.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>msTol</code>        | tolerance for the convergence criterion on the first iteration when <code>optim</code> is used. Default is 1e-7.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>msVerbose</code>    | a logical value passed as the trace argument to <a href="#">nlminb</a> or <code>optim</code> . Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>returnObject</code> | a logical value indicating whether the fitted object should be returned with a <a href="#">warning</a> (instead of an error via <code>stop()</code> ) when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                  |
| <code>gradHess</code>     | a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the internal optimization. This option is only available when the correlation structure ( <code>corStruct</code> ) and the variance function structure ( <code>varFunc</code> ) have no "varying" parameters and the <code>pdMat</code> classes used in the random effects structure are <code>pdSymm</code> (general positive-definite), <code>pdDiag</code> (diagonal), <code>pdIdent</code> (multiple of the identity), or <code>pdCompSymm</code> (compound symmetry). Default is TRUE. |
| <code>apVar</code>        | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                |                                                                                                                                                                                                                                                                                                              |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| .relStep       | relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .                                                                                                                                                                                                   |
| opt            | the optimizer to be used, either <code>"nlminb"</code> (the default) or <code>"optim"</code> .                                                                                                                                                                                                               |
| optimMethod    | character - the optimization method to be used with the <code>optim</code> optimizer. The default is <code>"BFGS"</code> . An alternative is <code>"L-BFGS-B"</code> .                                                                                                                                       |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is <code>0.05</code> .                                                                                                                                                                                 |
| natural        | a logical value indicating whether the <code>pdNatural</code> parametrization should be used for general positive-definite matrices ( <code>pdSymm</code> ) in <code>reStruct</code> , when the approximate covariance matrix of the estimators is calculated. Default is <code>TRUE</code> .                |
| sigma          | optionally a positive number to fix the residual error at. If <code>NULL</code> , as by default, or <code>0</code> , sigma is estimated.                                                                                                                                                                     |
| allow.n.lt.q   | <code>logical</code> indicating if it is ok to have less observations than random effects for each group. The default, <code>FALSE</code> signals an error; if <code>NA</code> , such a situation only gives a warning, as in <code>nlme</code> versions prior to 2019; if true, no message is given at all. |
| ...            | further named control arguments to be passed, depending on <code>opt</code> , to <code>nlminb</code> (those from <code>abs.tol</code> down) or <code>optim</code> (those except <code>trace</code> and <code>maxit</code> ; <code>reltol</code> is used only from the second iteration).                     |

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

Examples

```
decrease the maximum number iterations in the ms call and
request that information on the evolution of the ms iterations be printed
str(lCtr <- lmeControl(msMaxIter = 20, msVerbose = TRUE))
This should always work:
do.call(lmeControl, lCtr)
```

| lmeObject | <i>Fitted lme Object</i> |
|-----------|--------------------------|

---

Description

An object returned by the `lme` function, inheriting from class `"lme"` and representing a fitted linear mixed-effects model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `fixed.effects`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `pairs`, `plot`, `predict`, `print`, `random.effects`, `residuals`, `sigma`, `summary`, `update`, and `vcov`.

**Value**

The following components must be included in a legitimate "lme" object.

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apVar        | an approximate covariance matrix for the variance-covariance coefficients. If apVar = FALSE in the control values used in the call to lme, this component is NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| call         | a list containing an image of the lme call that produced the object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| coefficients | a list with two components, fixed and random, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the random list, the columns refer to the random effects and the rows to the groups.                                                                                                                                                                                                                                                                                                                                              |
| contrasts    | a list of the contrast matrices used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the lme model, this component will be an empty list.                                                                                                                                                                                                                                                                                                                            |
| dims         | a list with basic dimensions used in the lme fit, including the components N - the number of observations in the data, Q - the number of grouping levels, qvec - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), ngrps - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and ncol - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one). |
| fitted       | a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| fixDF        | a list with components X and terms specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| groups       | a data frame with the grouping factors as columns. The grouping level increases from left to right.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| logLik       | the (restricted) log-likelihood at convergence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| method       | the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| modelStruct  | an object inheriting from class lmeStruct, representing a list of mixed-effects model components, such as reStruct, corStruct, and varFunc objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| numIter      | the number of iterations used in the iterative algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| residuals    | a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| terms        | the <a href="#">terms</a> , including <a href="#">formula</a> , see also <a href="#">terms.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| sigma        | the estimated within-group error standard deviation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| varFix       | an approximate covariance matrix of the fixed effects estimates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

lmeStruct

*Linear Mixed-Effects Structure*

---

**Description**

A linear mixed-effects structure is a list of model components representing different sets of parameters in the linear mixed-effects model. An `lmeStruct` list must contain at least a `reStruct` object, but may also contain `corStruct` and `varFunc` objects. `NULL` arguments are not included in the `lmeStruct` list.

**Usage**

```
lmeStruct(reStruct, corStruct, varStruct)
```

**Arguments**

|                        |                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>reStruct</code>  | a <code>reStruct</code> representing a random effects structure.                                                    |
| <code>corStruct</code> | an optional <code>corStruct</code> object, representing a correlation structure. Default is <code>NULL</code> .     |
| <code>varStruct</code> | an optional <code>varFunc</code> object, representing a variance function structure. Default is <code>NULL</code> . |

**Value**

a list of model components determining the parameters to be estimated for the associated linear mixed-effects model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
lms1 <- lmeStruct(reStruct(~age), corAR1(), varPower())
```

---

lmList

---

*List of lm Objects with a Common Model*

---

**Description**

Data is partitioned according to the levels of the grouping factor `g` and individual `lm` fits are obtained for each data partition, using the model defined in `object`.

**Usage**

```
lmList(object, data, level, subset, na.action = na.fail,
 pool = TRUE, warn.lm = TRUE)

S3 method for class 'formula'
lmList(object, data, level, subset, na.action = na.fail,
 pool = TRUE, warn.lm = TRUE)

S3 method for class 'lmList'
update(object, formula., ..., evaluate = TRUE)
S3 method for class 'lmList'
print(x, pool, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | For <code>lmList</code> , either a linear formula object of the form $y \sim x_1 + \dots + x_n \mid g$ or a <code>groupedData</code> object. In the formula object, $y$ represents the response, $x_1, \dots, x_n$ the covariates, and $g$ the grouping factor specifying the partitioning of the data according to which different <code>lm</code> fits should be performed. The grouping factor $g$ may be omitted from the formula, in which case the grouping structure will be obtained from data, which must inherit from class <code>groupedData</code> . The method function <a href="#">lmList.groupedData</a> is documented separately. For the method <code>update.lmList</code> , <code>object</code> is an object inheriting from class <code>lmList</code> . |
| <code>formula</code>   | (used in <code>update.lmList</code> only) a two-sided linear formula with the common model for the individuals <code>lm</code> fits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>formula.</code>  | Changes to the formula – see <code>update.formula</code> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>data</code>      | a data frame in which to interpret the variables named in <code>object</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>level</code>     | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>subset</code>    | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>na.action</code> | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lmList</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>pool</code>      | an optional logical value indicating whether a pooled estimate of the residual standard error should be used in calculations of standard deviations or standard errors for summaries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|          |                                                                                                                                                                                     |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| warn.lm  | <a href="#">logical</a> indicating if <code>lm()</code> errors (all of which are caught by <code>tryCatch</code> ) should be signalled as a “summarizing” <a href="#">warning</a> . |
| x        | an object inheriting from class <code>lmList</code> to be printed.                                                                                                                  |
| ...      | some methods for this generic require additional arguments. None are used in this method.                                                                                           |
| evaluate | If TRUE evaluate the new call else return the call.                                                                                                                                 |

**Value**

a list of `lm` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `lmList` object.

**See Also**

[lm](#), [lme.lmList](#), [plot.lmList](#), [pooledSD](#), [predict.lmList](#), [residuals.lmList](#), [summary.lmList](#)

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
summary(fm1)
```

---

|                                 |                                             |
|---------------------------------|---------------------------------------------|
| <code>lmList.groupedData</code> | <i>lmList Fit from a groupedData Object</i> |
|---------------------------------|---------------------------------------------|

---

**Description**

The response variable and primary covariate in `formula(object)` are used to construct the linear model formula. This formula and the `groupedData` object are passed as the object and data arguments to `lmList.formula`, together with any other additional arguments in the function call. See the documentation on [lmList.formula](#) for a description of that function.

**Usage**

```
S3 method for class 'groupedData'
lmList(object, data, level, subset, na.action = na.fail,
 pool = TRUE, warn.lm = TRUE)
```

**Arguments**

|        |                                                                                                                      |
|--------|----------------------------------------------------------------------------------------------------------------------|
| object | a data frame inheriting from class " <a href="#">groupedData</a> ".                                                  |
| data   | this argument is included for consistency with the generic function. It is ignored in this method function.          |
| level  | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present. |

|               |                                                                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| subset        | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| na.action     | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lmList to print an error message and terminate if there are any incomplete observations.                                                                                                      |
| pool, warn.lm | optional <a href="#">logicals</a> , see <a href="#">lmList</a> .                                                                                                                                                                                                                                          |

**Value**

a list of lm objects with as many components as the number of groups defined by the grouping factor. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an lmList object.

**Examples**

```
fm1 <- lmList(Orthodont)
summary(fm1)
```

---

logDet

---

*Extract the Logarithm of the Determinant*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, several pdMat classes, and reStruct.

**Usage**

```
logDet(object, ...)
```

**Arguments**

|        |                                                                       |
|--------|-----------------------------------------------------------------------|
| object | any object from which a matrix, or list of matrices, can be extracted |
| ...    | some methods for this generic function require additional arguments.  |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|------------------|------------------------------------------|
| logDet.corStruct | <i>Extract corStruct Log-Determinant</i> |
|------------------|------------------------------------------|

---

## Description

This method function extracts the logarithm of the determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

## Usage

```
S3 method for class 'corStruct'
logDet(object, covariate, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | an object inheriting from class " <a href="#">corStruct</a> ", representing a correlation structure.                                                                                                                          |
| <code>covariate</code> | an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to <code>getCovariate(object)</code> . |
| <code>...</code>       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                     |

## Value

the log-determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```
cs1 <- corAR1(0.3)
logDet(cs1, covariate = 1:4)
```

---

|              |                                                    |
|--------------|----------------------------------------------------|
| logDet.pdMat | <i>Extract Log-Determinant from a pdMat Object</i> |
|--------------|----------------------------------------------------|

---

**Description**

This method function extracts the logarithm of the determinant of a square-root factor of the positive-definite matrix represented by object.

**Usage**

```
S3 method for class 'pdMat'
logDet(object, ...)
```

**Arguments**

|        |                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">pdMat</a> ", representing a positive definite matrix. |
| ...    | some methods for this generic require additional arguments. None are used in this method.           |

**Value**

the log-determinant of a square-root factor of the positive-definite matrix represented by object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
pd1 <- pdSymm(diag(1:3))
logDet(pd1)
```

---

|                 |                                          |
|-----------------|------------------------------------------|
| logDet.reStruct | <i>Extract reStruct Log-Determinants</i> |
|-----------------|------------------------------------------|

---

**Description**

Calculates, for each of the pdMat components of object, the logarithm of the determinant of a square-root factor.

**Usage**

```
S3 method for class 'reStruct'
logDet(object, ...)
```

**Arguments**

- |        |                                                                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                     |

**Value**

a vector with the log-determinants of square-root factors of the `pdMat` components of object.

**Author(s)**

José Pinheiro

**See Also**

[reStruct](#), [pdMat](#), [logDet](#)

**Examples**

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
 B = pdDiag(2 * diag(4), form = ~Educ)))
logDet(rs1)
```

---

logLik.corStruct

---

*Extract corStruct Log-Likelihood*

---

**Description**

This method function extracts the component of a Gaussian log-likelihood associated with the correlation structure, which is equal to the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the matrix (or matrices) represented by object.

**Usage**

```
S3 method for class 'corStruct'
logLik(object, data, ...)
```

**Arguments**

- |        |                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">corStruct</a> ", representing a correlation structure.                          |
| data   | this argument is included to make this method function compatible with other <code>logLik</code> methods and will be ignored. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                     |

**Value**

the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the correlation matrix (or matrices) represented by object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[logDet.corStruct](#), [logLik.lme](#),

**Examples**

```
cs1 <- corAR1(0.2)
cs1 <- Initialize(cs1, data = Orthodont)
logLik(cs1)
```

---

logLik.glsStruct

*Log-Likelihood of a glsStruct Object*

---

**Description**

Pars is used to update the coefficients of the model components of object and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the settings attribute of object.

**Usage**

```
S3 method for class 'glsStruct'
logLik(object, Pars, conLin, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                           |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">glsStruct</a> ", representing a list of linear model components, such as <a href="#">corStruct</a> and " <a href="#">varFunc</a> " objects.                                                                                                 |
| Pars   | the parameter values at which the (restricted) log-likelihood is to be evaluated.                                                                                                                                                                                                         |
| conLin | an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying linear model. Defaults to attr(object, "conLin"). |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                 |

**Value**

the (restricted) log-likelihood for the linear model described by object, evaluated at Pars.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

|-------------|----------------------------------------|
| logLik.gnls | <i>Log-Likelihood of a gnls Object</i> |
|-------------|----------------------------------------|

---

**Description**

Returns the log-likelihood value of the nonlinear model represented by object evaluated at the estimated coefficients.

**Usage**

```
S3 method for class 'gnls'
logLik(object, REML, ...)
```

**Arguments**

|        |                                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">gnls</a> ", representing a generalized nonlinear least squares fitted model. |
| REML   | an logical value for consistency with logLik, gls, but only FALSE is accepted..                                            |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                  |

**Value**

the log-likelihood of the linear model represented by object evaluated at the estimated coefficients.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

```
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
 weights = varPower())
logLik(fm1)
```

---

|                   |                                              |
|-------------------|----------------------------------------------|
| logLik.gnlsStruct | <i>Log-Likelihood of a gnlsStruct Object</i> |
|-------------------|----------------------------------------------|

---

**Description**

Pars is used to update the coefficients of the model components of object and the individual log-likelihood contributions of each component are added together.

**Usage**

```
S3 method for class 'gnlsStruct'
logLik(object, Pars, conLin, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                            |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>gnlsStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects, and attributes specifying the underlying nonlinear model and the response variable.                                                    |
| Pars   | the parameter values at which the log-likelihood is to be evaluated.                                                                                                                                                                                                                                       |
| conLin | an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nonlinear model. Defaults to <code>attr(object, "conLin")</code> . |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                  |

**Value**

the log-likelihood for the linear model described by object, evaluated at Pars.

logLik.lme

---

*Log-Likelihood of an lme Object*

---

**Description**

If `REML=FALSE`, returns the log-likelihood value of the linear mixed-effects model represented by object evaluated at the estimated coefficients; else, the restricted log-likelihood evaluated at the estimated coefficients is returned.

**Usage**

```
S3 method for class 'lme'
logLik(object, REML, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                     |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.                                                                                                                                                                          |
| REML   | an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to the method of estimation used, that is TRUE if and only object was fitted with method = "REML" (the default for these fitting functions). |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                           |

**Value**

the (restricted) log-likelihood of the model represented by object evaluated at the estimated coefficients.

logLik.lmList

*Log-Likelihood of an lmList Object*

---

**Description**

If pool=FALSE, the (restricted) log-likelihoods of the lm components of object are summed together. Else, the (restricted) log-likelihood of the lm fit with different coefficients for each level of the grouping factor associated with the partitioning of the object components is obtained.

**Usage**

```
S3 method for class 'lmList'
logLik(object, REML, pool, ...)
```

**Arguments**

|        |                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">lmList</a> ", representing a list of lm objects with a common model.                                        |
| REML   | an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE.          |
| pool   | an optional logical value indicating whether all lm components of object may be assumed to have the same error variance. Default is attr(object, "pool"). |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                 |

**Value**

either the sum of the (restricted) log-likelihoods of each lm component in object, or the (restricted) log-likelihood for the lm fit with separate coefficients for each component of object.

**Author(s)**

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
logLik(fm1) # returns NA when it should not
```

logLik.reStruct

*Calculate reStruct Log-Likelihood***Description**

Calculates the log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)`. The `settings` attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods are described in Bates and Pinheiro (1998).

**Usage**

```
S3 method for class 'reStruct'
logLik(object, conLin, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class " <b>reStruct</b> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.                                                                                                                                             |
| <code>conLin</code> | a condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying model. |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                        |

**Value**

the log-likelihood, or restricted log-likelihood, of linear mixed-effects model represented by `object` and `conLin`, evaluated at `coef{object}`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|----------------|-------------------------------|
| logLik.varFunc | <i>Extract varFunc logLik</i> |
|----------------|-------------------------------|

---

### Description

This method function extracts the component of a Gaussian log-likelihood associated with the variance function structure represented by object, which is equal to the sum of the logarithms of the corresponding weights.

### Usage

```
S3 method for class 'varFunc'
logLik(object, data, ...)
```

### Arguments

|        |                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">varFunc</a> ", representing a variance function structure.         |
| data   | this argument is included to make this method function compatible with other logLik methods and will be ignored. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                        |

### Value

the sum of the logarithms of the weights corresponding to the variance function structure represented by object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[logLik.lme](#)

### Examples

Machines*Productivity Scores for Machines and Workers*

---

**Description**

The Machines data frame has 54 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Worker** an ordered factor giving the unique identifier for the worker.

**Machine** a factor with levels A, B, and C identifying the machine brand.

**score** a productivity score.

**Details**

Data on an experiment to compare three brands of machines used in an industrial process are presented in Milliken and Johnson (p. 285, 1992). Six workers were chosen randomly among the employees of a factory to operate each machine three times. The response is an overall productivity score taking into account the number and quality of components produced.

MathAchieve*Mathematics achievement scores*

---

**Description**

The MathAchieve data frame has 7185 rows and 6 columns.

**Format**

This data frame contains the following columns:

**School** an ordered factor identifying the school that the student attends

**Minority** a factor with levels No Yes indicating if the student is a member of a minority racial group.

**Sex** a factor with levels Male Female

**SES** a numeric vector of socio-economic status.

**MathAch** a numeric vector of mathematics achievement scores.

**MEANSES** a numeric vector of the mean SES for the school.

Details

Each row in this data frame contains the data for one student.

Examples

```
summary(MathAchieve)
```

---

|               |                                                |
|---------------|------------------------------------------------|
| MathAchSchool | <i>School demographic data for MathAchieve</i> |
|---------------|------------------------------------------------|

---

Description

The MathAchSchool data frame has 160 rows and 7 columns.

Format

This data frame contains the following columns:

- School** a factor giving the school on which the measurement is made.
- Size** a numeric vector giving the number of students in the school
- Sector** a factor with levels Public Catholic
- PRACAD** a numeric vector giving the percentage of students on the academic track
- DISCLIM** a numeric vector measuring the discrimination climate
- HIMINTY** a factor with levels 0 1
- MEANSES** a numeric vector giving the mean SES score.

Details

These variables give the school-level demographic data to accompany the MathAchieve data.

|        |                             |
|--------|-----------------------------|
| Matrix | <i>Assign Matrix Values</i> |
|--------|-----------------------------|

---

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include pdMat, pdBlocked, and reStruct.

Usage

```
matrix(object) <- value
```

Arguments

- object any object to which as.matrix can be applied.
- value a matrix, or list of matrices, with the same dimensions as as.matrix(object) with the new values to be assigned to the matrix associated with object.

**Value**

will depend on the method function; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`as.matrix`, also for examples, `matrix<- .pdMat`, `matrix<- .reStruct`.

---

|              |                                                     |
|--------------|-----------------------------------------------------|
| Matrix.pdMat | <i>Assign Matrix to a pdMat or pdBlocked Object</i> |
|--------------|-----------------------------------------------------|

---

**Description**

The positive-definite matrix represented by object is replaced by value. If the original matrix had row and/or column names, the corresponding names for value can either be NULL, or a permutation of the original names.

**Usage**

```
S3 replacement method for class 'pdMat'
matrix(object) <- value
S3 replacement method for class 'pdBlocked'
matrix(object) <- value
```

**Arguments**

|        |                                                                                                                                                                      |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <code>pdMat</code> ", representing a positive definite matrix.                                                                     |
| value  | a matrix with the new values to be assigned to the positive-definite matrix represented by object. Must have the same dimensions as <code>as.matrix(object)</code> . |

**Value**

a `pdMat` or `pdBlocked` object similar to object, but with its coefficients modified to produce the matrix in value.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`pdMat`, "`matrix<-`"

**Examples**

```
class(pd1 <- pdSymm(diag(3))) # "pdSymm" "pdMat"
matrix(pd1) <- diag(1:3)
pd1
```

---

|                 |                          |
|-----------------|--------------------------|
| Matrix.reStruct | Assign reStruct Matrices |
|-----------------|--------------------------|

---

**Description**

The individual matrices in value are assigned to each pdMat component of object, in the order they are listed. The new matrices must have the same dimensions as the matrices they are meant to replace.

**Usage**

```
S3 replacement method for class 'reStruct'
matrix(object) <- value
```

**Arguments**

- object            an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- value            a matrix, or list of matrices, with the new values to be assigned to the matrices associated with the pdMat components of object.

**Value**

an reStruct object similar to object, but with the coefficients of the individual pdMat components modified to produce the matrices listed in value.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

```

**Examples**

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
matrix(rs1) <- list(diag(2), 3)
```

---

|      |                    |
|------|--------------------|
| Meat | Tenderness of meat |
|------|--------------------|

---

**Description**

The Meat data frame has 30 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Storage** an ordered factor specifying the storage treatment - 1 (0 days), 2 (1 day), 3 (2 days), 4 (4 days), 5 (9 days), and 6 (18 days)

**score** a numeric vector giving the tenderness score of beef roast.

**Block** an ordered factor identifying the muscle from which the roast was extracted with levels II < V < I < III < IV

**Pair** an ordered factor giving the unique identifier for each pair of beef roasts with levels II-1 < ... < IV-1

**Details**

Cochran and Cox (section 11.51, 1957) describe data from an experiment conducted at Iowa State College (Paul, 1943) to compare the effects of length of cold storage on the tenderness of beef roasts. Six storage periods ranging from 0 to 18 days were used. Thirty roasts were scored by four judges on a scale from 0 to 10, with the score increasing with tenderness. The response was the sum of all four scores. Left and right roasts from the same animal were grouped into pairs, which were further grouped into five blocks, according to the muscle from which they were extracted. Different storage periods were applied to each roast within a pair according to a balanced incomplete block design.

|------|--------------------------------------|
| Milk | <i>Protein content of cows' milk</i> |
|------|--------------------------------------|

---

**Description**

The Milk data frame has 1337 rows and 4 columns.

**Format**

This data frame contains the following columns:

**protein** a numeric vector giving the protein content of the milk.

**Time** a numeric vector giving the time since calving (weeks).

**Cow** an ordered factor giving a unique identifier for each cow.

**Diet** a factor with levels barley, barley+lupins, and lupins identifying the diet for each cow.

**Details**

Diggle, Liang, and Zeger (1994) describe data on the protein content of cows' milk in the weeks following calving. The cattle are grouped according to whether they are fed a diet with barley alone, with barley and lupins, or with lupins alone.

**Source**

---

model.matrix.reStruct *reStruct Model Matrix*

---

## Description

The model matrices for each element of `formula(object)`, calculated using data, are bound together column-wise. When multiple grouping levels are present (i.e. when `length(object) > 1`), the individual model matrices are combined from innermost (at the leftmost position) to outermost (at the rightmost position).

## Usage

```
S3 method for class 'reStruct'
model.matrix(object, data, contrast, ...)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>   | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.                                                                                                                                                                                                                                     |
| <code>data</code>     | a data frame in which to evaluate the variables defined in <code>formula(object)</code> .                                                                                                                                                                                                                                                                                                         |
| <code>contrast</code> | an optional named list specifying the contrasts to be used for representing the factor variables in data. The components names should match the names of the variables in data for which the contrasts are to be specified. The components of this list will be used as the <code>contrasts</code> attribute of the corresponding factor. If missing, the default contrast specification is used. |
| <code>...</code>      | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                         |

## Value

a matrix obtained by binding together, column-wise, the model matrices for each element of `formula(object)`.

|--------|---------------------------------------------|
| Muscle | <i>Contraction of heart muscle sections</i> |
|--------|---------------------------------------------|

---

### Description

The Muscle data frame has 60 rows and 3 columns.

### Format

This data frame contains the following columns:

**Strip** an ordered factor indicating the strip of muscle being measured.

**conc** a numeric vector giving the concentration of CaCl<sub>2</sub>

**length** a numeric vector giving the shortening of the heart muscle strip.

### Details

Baumann and Waldvogel (1963) describe data on the shortening of heart muscle strips dipped in a CaCl<sub>2</sub> solution. The muscle strips are taken from the left auricle of a rat's heart.

### Source

|-------|----------------------------------------|
| Names | <i>Names Associated with an Object</i> |
|-------|----------------------------------------|

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: formula, pdBlocked, pdMat, and reStruct.

### Usage

```
Names(object, ...)
Names(object, ...) <- value
```

### Arguments

|        |                                                                      |
|--------|----------------------------------------------------------------------|
| object | any object for which names can be extracted and/or assigned.         |
| ...    | some methods for this generic function require additional arguments. |
| value  | names to be assigned to object.                                      |

### Value

will depend on the method function used; see the appropriate documentation.

**SIDE EFFECTS**

On the left side of an assignment, sets the names associated with object to value, which must have an appropriate length.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|---------------|-------------------------------------|
| Names.formula | <i>Extract Names from a formula</i> |
|---------------|-------------------------------------|

---

**Description**

This method function returns the names of the terms corresponding to the right hand side of object (treated as a linear formula), obtained as the column names of the corresponding model.matrix.

**Usage**

```
S3 method for class 'formula'
Names(object, data, exclude, ...)
```

**Arguments**

- |         |                                                                                                                                                                  |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | an object inheriting from class " <a href="#">formula</a> ".                                                                                                     |
| data    | an optional data frame containing the variables specified in object. By default the variables are taken from the environment from which Names.formula is called. |
| exclude | an optional character vector with names to be excluded from the returned value. Default is c("pi", ".").                                                         |
| ...     | some methods for this generic require additional arguments. None are used in this method.                                                                        |

**Value**

a character vector with the column names of the model.matrix corresponding to the right hand side of object which are not listed in excluded.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

Names(distance ~ Sex * age, data = Orthodont)
```

---

Names.pdBlocked*Names of a pdBlocked Object*

---

## Description

This method function extracts the first element of the Dimnames attribute, which contains the column names, for each block diagonal element in the matrix represented by object.

## Usage

```
S3 method for class 'pdBlocked'
Names(object, asList, ...)
```

## Arguments

|        |                                                                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">pdBlocked</a> " representing a positive-definite matrix with block diagonal structure                                           |
| asList | a logical value. If TRUE a list with the names for each block diagonal element is returned. If FALSE a character vector with all column names is returned. Defaults to FALSE. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                     |

## Value

if asList is FALSE, a character vector with column names of the matrix represented by object; otherwise, if asList is TRUE, a list with components given by the column names of the individual block diagonal elements in the matrix represented by object.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

Names.pdMat

*Names of a pdMat Object***Description**

This method function returns the first element of the Dimnames attribute of object, which contains the column names of the matrix represented by object.

**Usage**

```
S3 method for class 'pdMat'
Names(object, ...)
S3 replacement method for class 'pdMat'
Names(object, ...) <- value
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                   |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">pdMat</a> ", representing a positive-definite matrix.                                                                                                                                                                                                               |
| value  | a character vector with the replacement values for the column and row names of the matrix represented by object. It must have length equal to the dimension of the matrix represented by object and, if names have been previously assigned to object, it must correspond to a permutation of the original names. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                         |

**Value**

if object has a Dimnames attribute then the first element of this attribute is returned; otherwise NULL.

**SIDE EFFECTS**

On the left side of an assignment, sets the Dimnames attribute of object to list(value, value).

|------------|----------------------------------|
| needUpdate | <i>Check if Update is Needed</i> |
|------------|----------------------------------|

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. By default, it tries to extract a `needUpdate` attribute of object. If this is `NULL` or `FALSE` it returns `FALSE`; else it returns `TRUE`. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

**Usage**

```
needUpdate(object)
```

**Arguments**

|        |            |
|--------|------------|
| object | any object |
|--------|------------|

**Value**

a logical value indicating whether object needs to be updated.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[needUpdate.modelStruct](#)

**Examples**

```
vf1 <- varExp()
vf1 <- Initialize(vf1, data = Orthodont)
needUpdate(vf1)
```

---

|                        |                                                     |
|------------------------|-----------------------------------------------------|
| needUpdate.modelStruct | <i>Check if a modelStruct Object Needs Updating</i> |
|------------------------|-----------------------------------------------------|

---

**Description**

This method function checks if any of the elements of object needs to be updated. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

**Usage**

```
S3 method for class 'modelStruct'
needUpdate(object)
```

**Arguments**

**object** an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects.

**Value**

a logical value indicating whether any element of object needs to be updated.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
 varStruct = varPower(form = ~age))
needUpdate(lms1)
```

---

Nitrendipene

*Assay of nitrendipene*

---

**Description**

The Nitrendipene data frame has 89 rows and 4 columns.

**Format**

This data frame contains the following columns:

**activity** a numeric vector

**NIF** a numeric vector

**Tissue** an ordered factor with levels 2 < 1 < 3 < 4

**log.NIF** a numeric vector

**Source**

Bates, D. M. and Watts, D. G. (1988), *Nonlinear Regression Analysis and Its Applications*, Wiley, New York.

nlme

*Nonlinear Mixed-Effects Models***Description**

This generic function fits a nonlinear mixed-effects model in the formulation described in Lindstrom and Bates (1990) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
nlme(model, data, fixed, random, groups, start, correlation, weights,
 subset, method, na.action, naPattern, control, verbose)
```

```
S3 method for class 'formula'
```

```
nlme(model, data, fixed, random, groups, start, correlation, weights,
 subset, method, na.action, naPattern, control, verbose)
```

**Arguments**

- |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| model  | a nonlinear model formula, with the response on the left of a <code>~</code> operator and an expression involving parameters and covariates on the right, or an <code>nlsList</code> object. If data is given, all names used in the formula should be defined as parameters or variables in the data frame. The method function <code>nlme.nlsList</code> is documented separately.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| data   | an optional data frame containing the variables named in model, fixed, random, correlation, weights, subset, and naPattern. By default the variables are taken from the environment from which nlme is called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| fixed  | a two-sided linear formula of the form $f_1 + \dots + f_n \sim x_1 + \dots + x_m$ , or a list of two-sided formulas of the form $f_1 \sim x_1 + \dots + x_m$ , with possibly different models for different parameters. The $f_1, \dots, f_n$ are the names of parameters included on the right hand side of model and the $x_1 + \dots + x_m$ expressions define linear models for these parameters (when the left hand side of the formula contains several parameters, they all are assumed to follow the same linear model, described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| random | optionally, any of the following: (i) a two-sided formula of the form $r_1 + \dots + r_n \sim x_1 + \dots + x_m \mid g_1 / \dots / g_Q$ , with $r_1, \dots, r_n$ naming parameters included on the right hand side of model, $x_1 + \dots + x_m$ specifying the random-effects model for these parameters and $g_1 / \dots / g_Q$ the grouping structure ( $Q$ may be equal to 1, in which case no <code>/</code> is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a two-sided formula of the form $r_1 + \dots + r_n \sim x_1 + \dots + x_m$ , a list of two-sided formulas of the form $r_1 \sim x_1 + \dots + x_m$ , with possibly different random-effects models for different parameters, a <code>pdMat</code> object with a two-sided formula, or list of two-sided formulas (i.e. a non-NULL value for <code>formula(random)</code> ), or a list of <code>pdMat</code> objects with two-sided formulas, or lists of two-sided formulas. In this case, the grouping structure formula will be given in groups, or derived from the data used to fit the nonlinear mixed-effects model, which should inherit from class <code>groupedData</code> ; (iii) a named list of formulas, lists of formulas, or <code>pdMat</code> |

objects as in (ii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (iv) an `reStruct` object. See the documentation on [pdClasses](#) for a description of the available `pdMat` classes. Defaults to fixed, resulting in all fixed effects having also random effects.

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>groups</code>      | an optional one-sided formula of the form <code>~g1</code> (single level of nesting) or <code>~g1/.../gQ</code> (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. <code>g1, ..., gQ</code> must evaluate to factors in data. The order of nesting, when multiple levels are present, is taken from left to right (i.e. <code>g1</code> is the first level, <code>g2</code> the second, etc.).                                                                                                                                                                                                                                                                                                                                                           |
| <code>start</code>       | an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component <code>fixed</code> , given by the vector. The <code>fixed</code> component is required, unless the model function inherits from class <code>selfStart</code> , in which case initial values will be derived from a call to <code>nlsList</code> . An optional random component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level. |
| <code>correlation</code> | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <a href="#">corClasses</a> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>weights</code>     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <a href="#">varClasses</a> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.                                                                                                                                                                                                                                                                                                                                                         |
| <code>subset</code>      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>method</code>      | a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"ML"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>na.action</code>   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlme</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>naPattern</code>   | an expression or formula object, specifying which returned values are to be regarded as missing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>control</code>     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>nlmeControl</code> . Defaults to an empty list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>verbose</code>     | an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Value

an object of class `nlme` representing the nonlinear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `nlmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

**Note**

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

The model formulation and computational methods are described in Lindstrom, M.J. and Bates, D.M. (1990). The variance-covariance parametrizations are described in Pinheiro and Bates (1996).

**Examples**

```
fm1 <- nlme(height ~ SSasym(age, Asym, R0, lrc),
 data = Loblolly,
 fixed = Asym + R0 + lrc ~ 1,
 random = Asym ~ 1,
 start = c(Asym = 103, R0 = -8.5, lrc = -3.3))
summary(fm1)
fm2 <- update(fm1, random = pdDiag(Asym + lrc ~ 1))
summary(fm2)
```

---

nlme.nlsList

---

*NLME fit from nlsList Object*

---

**Description**

If the random effects names defined in random are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in random). `formula(fixed)` and the data argument in the calling sequence used to obtain fixed are passed as the fixed and data arguments to `nlme.formula`, together with any other additional arguments in the function call. See the documentation on [nlme.formula](#) for a description of that function.

**Usage**

```
S3 method for class 'nlsList'
nlme(model, data, fixed, random, groups, start, correlation, weights,
 subset, method, na.action, naPattern, control, verbose)
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| model       | an object inheriting from class " <a href="#">nlsList</a> ", representing a list of nls fits with a common model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| data        | this argument is included for consistency with the generic function. It is ignored in this method function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| fixed       | this argument is included for consistency with the generic function. It is ignored in this method function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| random      | an optional one-sided linear formula with no conditioning expression, or a <code>pdMat</code> object with a <code>formula</code> attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of <code>formula(fixed)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| groups      | an optional one-sided formula of the form <code>~g1</code> (single level of nesting) or <code>~g1/.../gQ</code> (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. <code>g1, ..., gQ</code> must evaluate to factors in data. The order of nesting, when multiple levels are present, is taken from left to right (i.e. <code>g1</code> is the first level, <code>g2</code> the second, etc.).                                                                                                                                                                                                                                                                                                                                                           |
| start       | an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component <code>fixed</code> , given by the vector. The <code>fixed</code> component is required, unless the model function inherits from class <code>selfStart</code> , in which case initial values will be derived from a call to <code>nlsList</code> . An optional random component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level. |
| correlation | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <a href="#">corClasses</a> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| weights     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <a href="#">varClasses</a> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.                                                                                                                                                                                                                                                                                                                                                         |
| subset      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| method      | a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"ML"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| na.action   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlme</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| naPattern   | an expression or formula object, specifying which returned values are to be regarded as missing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| control     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>nlmeControl</code> . Defaults to an empty list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| verbose     | an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Value**

an object of class `nlme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `nlmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

The computational methods follow on the general framework of Lindstrom, M.J. and Bates, D.M. (1988). The model formulation is described in Laird, N.M. and Ware, J.H. (1982). The variance-covariance parametrizations are described in <Pinheiro, J.C. and Bates., D.M. (1996). The different correlation structures available for the `correlation` argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littell, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian, M. and Giltinan, D.M. (1995).

nlmeControl *Control Values for nlme Fit*

---

**Description**

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the nlme function.

**Usage**

```
nlmeControl(maxIter, pnlsMaxIter, msMaxIter, minScale,
 tolerance, niterEM, pnlsTol, msTol,
 returnObject, msVerbose, msWarnNoConv,
 gradHess, apVar, .relStep, minAbsParApVar = 0.05,
 opt = c("nlminb", "nlm"), natural = TRUE, sigma = NULL, ...)
```

**Arguments**

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maxIter      | maximum number of iterations for the nlme optimization algorithm. Default is 50.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| pnlsMaxIter  | maximum number of iterations for the PNLS optimization step inside the nlme optimization. Default is 7.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| msMaxIter    | maximum number of iterations for <a href="#">nlminb</a> (iter.max) or the <a href="#">nlm</a> (iterlim, from the 10-th step) optimization step inside the nlme optimization. Default is 50 (which may be too small for e.g. for overparametrized cases).                                                                                                                                                                                                                                                                    |
| minScale     | minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the PNLS step. Default 0.001.                                                                                                                                                                                                                                                                                                                                                                                       |
| tolerance    | tolerance for the convergence criterion in the nlme algorithm. Default is 1e-6.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| niterEM      | number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.                                                                                                                                                                                                                                                                                                                                                                       |
| pnlsTol      | tolerance for the convergence criterion in PNLS step. Default is 1e-3.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| msTol        | tolerance for the convergence criterion in nlm, passed as the gradtol argument to the function (see documentation on nlm). Default is 1e-7.                                                                                                                                                                                                                                                                                                                                                                                 |
| returnObject | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.                                                                                                                                                                                                                                                                                                                                            |
| msVerbose    | a logical value passed as the trace to <a href="#">nlminb</a> (..., control= list(trace = *, ...)) or as argument print.level to <a href="#">nlm</a> (). Default is FALSE.                                                                                                                                                                                                                                                                                                                                                  |
| msWarnNoConv | logical indicating if a <a href="#">warning</a> should be signalled whenever the minimization (by opt) in the LME step does not converge; defaults to TRUE.                                                                                                                                                                                                                                                                                                                                                                 |
| gradHess     | a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the nlm optimization. This option is only available when the correlation structure (corStruct) and the variance function structure (varFunc) have no "varying" parameters and the pdMat classes used in the random effects structure are pdSymm (general positive-definite), pdDiag (diagonal), pdIdent (multiple of the identity), or pdCompSymm (compound symmetry). Default is TRUE. |

|                |                                                                                                                                                                                                                                                                                 |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apVar          | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.                                                                                                                               |
| .relStep       | relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .                                                                                                                                                                      |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is <code>0.05</code> .                                                                                                                                                    |
| opt            | the optimizer to be used, either <code>"nlminb"</code> (the default) or <code>"nlm"</code> .                                                                                                                                                                                    |
| natural        | a logical value indicating whether the <code>pdNatural</code> parametrization should be used for general positive-definite matrices ( <code>pdSymm</code> ) in <code>reStruct</code> , when the approximate covariance matrix of the estimators is calculated. Default is TRUE. |
| sigma          | optionally a positive number to fix the residual error at. If NULL, as by default, or <code>0</code> , sigma is estimated.                                                                                                                                                      |
| ...            | Further, named control arguments to be passed to <code>nlminb</code> (apart from <code>trace</code> and <code>iter.max</code> mentioned above), where used ( <code>eval.max</code> and those from <code>abs.tol</code> down).                                                   |

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

|------------|---------------------------|

---

Description

An object returned by the `nlme` function, inheriting from class `"nlme"`, also inheriting from class `"lme"`, and representing a fitted nonlinear mixed-effects model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `fixed.effects`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `pairs`, `plot`, `predict`, `print`, `random.effects`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate "nlme" object.

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apVar        | an approximate covariance matrix for the variance-covariance coefficients. If apVar = FALSE in the control values used in the call to nlme, this component is NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| call         | a list containing an image of the nlme call that produced the object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| coefficients | a list with two components, fixed and random, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the random list, the columns refer to the random effects and the rows to the groups.                                                                                                                                                                                                                                                                                                                                               |
| contrasts    | a list of the contrast matrices used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the nlme model, this component will be an empty list.                                                                                                                                                                                                                                                                                                                            |
| dims         | a list with basic dimensions used in the nlme fit, including the components N - the number of observations in the data, Q - the number of grouping levels, qvec - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), ngrps - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and ncol - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one). |
| fitted       | a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| fixDF        | a list with components X and terms specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| groups       | a data frame with the grouping factors as columns. The grouping level increases from left to right.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| logLik       | the (restricted) log-likelihood at convergence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| map          | a list with components fmap, rmap, rmapRe1, and bmap, specifying various mappings for the fixed and random effects, used to generate predictions from the fitted object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| method       | the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| modelStruct  | an object inheriting from class nlmeStruct, representing a list of mixed-effects model components, such as reStruct, corStruct, and varFunc objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| numIter      | the number of iterations used in the iterative algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| residuals    | a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| sigma        | the estimated within-group error standard deviation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| varFix       | an approximate covariance matrix of the fixed effects estimates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|------------|------------------------------------------|
| nlmeStruct | <i>Nonlinear Mixed-Effects Structure</i> |
|------------|------------------------------------------|

---

**Description**

A nonlinear mixed-effects structure is a list of model components representing different sets of parameters in the nonlinear mixed-effects model. An `nlmeStruct` list must contain at least a `reStruct` object, but may also contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `nlmeStruct` list.

**Usage**

```
nlmeStruct(reStruct, corStruct, varStruct)
```

**Arguments**

|                        |                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------|
| <code>reStruct</code>  | a <code>reStruct</code> representing a random effects structure.                                      |
| <code>corStruct</code> | an optional <code>corStruct</code> object, representing a correlation structure. Default is NULL.     |
| <code>varStruct</code> | an optional <code>varFunc</code> object, representing a variance function structure. Default is NULL. |

**Value**

a list of model components determining the parameters to be estimated for the associated nonlinear mixed-effects model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

nlms1 <- nlmeStruct(reStruct(~age), corAR1(), varPower())
```

nlsList

*List of nls Objects with a Common Model***Description**

Data is partitioned according to the levels of the grouping factor defined in `model` and individual `nls` fits are obtained for each data partition, using the model defined in `model`.

**Usage**

```
nlsList(model, data, start, control, level, subset,
 na.action = na.fail, pool = TRUE, warn.nls = NA)

S3 method for class 'formula'
nlsList(model, data, start, control, level, subset,
 na.action = na.fail, pool = TRUE, warn.nls = NA)

S3 method for class 'nlsList'
update(object, model., ..., evaluate = TRUE)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | an object inheriting from class <code>nlsList</code> , representing a list of fitted <code>nls</code> objects.                                                                                                                                                                                                                                   |
| <code>model</code>     | either a nonlinear model formula, with the response on the left of a <code>~</code> operator and an expression involving parameters, covariates, and a grouping factor separated by the <code> </code> operator on the right, or a <code>selfStart</code> function. The method function <code>nlsList.selfStart</code> is documented separately. |
| <code>model.</code>    | changes to the model – see <code>update.formula</code> for details.                                                                                                                                                                                                                                                                              |
| <code>data</code>      | a data frame in which to interpret the variables named in <code>model</code> .                                                                                                                                                                                                                                                                   |
| <code>start</code>     | an optional named list with initial values for the parameters to be estimated in <code>model</code> . It is passed as the <code>start</code> argument to each <code>nls</code> call and is required when the nonlinear function in <code>model</code> does not inherit from class <code>selfStart</code> .                                       |
| <code>control</code>   | a list of control values passed as the <code>control</code> argument to <code>nls</code> . Defaults to an empty list.                                                                                                                                                                                                                            |
| <code>level</code>     | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.                                                                                                                                                                                                                             |
| <code>subset</code>    | an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                        |
| <code>na.action</code> | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlsList</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                |
| <code>pool</code>      | an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for <code>pool</code> in calculations of standard deviations or standard errors for summaries.                                                                                                                               |
| <code>warn.nls</code>  | <b>logical</b> indicating if <code>nls()</code> errors (all of which are caught by <code>tryCatch</code> ) should be signalled as a “summarizing” <b>warning</b> .                                                                                                                                                                               |

... some methods for this generic require additional arguments. None are used in this method.

evaluate If TRUE evaluate the new call else return the call.

### Details

As `nls(.)` is called on each sub group, and convergence of these may be problematic, these calls happen with error catching.

Since **nlme** version 3.1-127 (2016-04), all the errors are caught (via `tryCatch`) and if present, a “summarizing” **warning** is stored as attribute of the resulting “nlsList” object and signalled unless suppressed by `warn.nls = FALSE` or currently also when `warn.nls = NA` (default) and `getOption("show.error.messages")` is false.

`nlsList()` originally had used `try(*)` (with its default `silent=FALSE`) and hence all errors were printed to the console *unless* the global option `show.error.messages` was set to true. This still works, but has been *deprecated*.

### Value

a list of nls objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

### Examples

```
fm1 <- nlsList(uptake ~ SSasymptOff(conc, Asym, lrc, c0),
 data = C02, start = c(Asym = 30, lrc = -4.5, c0 = 52))
summary(fm1)
cfm1 <- confint(fm1) # via profiling each % FIXME: only *one* message instead of one *each*
mat.class <- class(matrix(1)) # ("matrix", "array") for R >= 4.0.0; ("matrix" in older R)
i.ok <- which(vapply(cfm1,
 function(r) identical(class(r), mat.class), NA))
stopifnot(length(i.ok) > 0, !anyNA(match(c(2:4, 6:9, 12), i.ok)))
where as (some of) the others gave errors during profile re-fitting :
str(cfm1[- i.ok])
```

---

`nlsList.selfStart`

*nlsList Fit from a selfStart Function*

---

### Description

The response variable and primary covariate in `formula(data)` are used together with `model` to construct the nonlinear model formula. This is used in the `nls` calls and, because a self-starting model function can calculate initial estimates for its parameters from the data, no starting estimates need to be provided.

**Usage**

```
S3 method for class 'selfStart'
nlsList(model, data, start, control, level, subset,
 na.action = na.fail, pool = TRUE, warn.nls = NA)
```

**Arguments**

|                             |                                                                                                                                                                                                                                                                                                                           |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code>          | a " <a href="#">selfStart</a> " model function, which calculates initial estimates for the model parameters from data.                                                                                                                                                                                                    |
| <code>data</code>           | a data frame in which to interpret the variables in <code>model</code> . Because no grouping factor can be specified in <code>model</code> , <code>data</code> must inherit from class " <a href="#">groupedData</a> ".                                                                                                   |
| <code>start</code>          | an optional named list with initial values for the parameters to be estimated in <code>model</code> . It is passed as the <code>start</code> argument to each <code>nls</code> call and is required when the nonlinear function in <code>model</code> does not inherit from class <code>selfStart</code> .                |
| <code>control</code>        | a list of control values passed as the <code>control</code> argument to <code>nls</code> . Defaults to an empty list.                                                                                                                                                                                                     |
| <code>level</code>          | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.                                                                                                                                                                                                      |
| <code>subset</code>         | an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| <code>na.action</code>      | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlsList</code> to print an error message and terminate if there are any incomplete observations.                                                                                         |
| <code>pool, warn.nls</code> | optional <a href="#">logicals</a> , see <a href="#">nlsList</a> .                                                                                                                                                                                                                                                         |

**Value**

a list of `nls` objects with as many components as the number of groups defined by the grouping factor. A `NULL` value is assigned to the components corresponding to clusters for which the `nls` algorithm failed to converge. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

Oats

*Split-plot Experiment on Varieties of Oats***Description**

The Oats data frame has 72 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Block** an ordered factor with levels VI < V < III < IV < II < I

**Variety** a factor with levels Golden Rain Marvellous Victory

**nitro** a numeric vector

**yield** a numeric vector

**Details**

These data have been introduced by Yates (1935) as an example of a split-plot design. The treatment structure used in the experiment was a  $3 \times 4$  full factorial, with three varieties of oats and four concentrations of nitrogen. The experimental units were arranged into six blocks, each with three whole-plots subdivided into four subplots. The varieties of oats were assigned randomly to the whole-plots and the concentrations of nitrogen to the subplots. All four concentrations of nitrogen were used on each whole-plot.

Orthodont

*Growth curve data on an orthodontic measurement***Description**

The Orthodont data frame has 108 rows and 4 columns of the change in an orthodontic measurement over time for several young subjects.

**Format**

This data frame contains the following columns:

**distance** a numeric vector of distances from the pituitary to the pterygomaxillary fissure (mm). These distances are measured on x-ray images of the skull.

**age** a numeric vector of ages of the subject (yr).

**Subject** an ordered factor indicating the subject on which the measurement was made. The levels are labelled M01 to M16 for the males and F01 to F13 for the females. The ordering is by increasing average distance within sex.

**Sex** a factor with levels Male and Female

### Details

Investigators at the University of North Carolina Dental School followed the growth of 27 children (16 males, 11 females) from age 8 until age 14. Every two years they measured the distance between the pituitary and the pterygomaxillary fissure, two points that are easily identified on x-ray exposures of the side of the head.

|       |                                    |
|-------|------------------------------------|
| Ovary | <i>Counts of Ovarian Follicles</i> |
|-------|------------------------------------|

---

### Description

The Ovary data frame has 308 rows and 3 columns.

### Format

This data frame contains the following columns:

**Mare** an ordered factor indicating the mare on which the measurement is made.

**Time** time in the estrus cycle. The data were recorded daily from 3 days before ovulation until 3 days after the next ovulation. The measurement times for each mare are scaled so that the ovulations for each mare occur at times 0 and 1.

**follicles** the number of ovarian follicles greater than 10 mm in diameter.

### Details

Pierson and Ginther (1987) report on a study of the number of large ovarian follicles detected in different mares at several times in their estrus cycles.

Oxboys

*Heights of Boys in Oxford***Description**

The Oxboys data frame has 234 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** an ordered factor giving a unique identifier for each boy in the experiment

**age** a numeric vector giving the standardized age (dimensionless)

**height** a numeric vector giving the height of the boy (cm)

**Occasion** an ordered factor - the result of converting age from a continuous variable to a count so these slightly unbalanced data can be analyzed as balanced.

**Details**

These data are described in Goldstein (1987) as data on the height of a selection of boys from Oxford, England versus a standardized age.

**Source**

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York. (Appendix A.19)

Oxide

*Variability in Semiconductor Manufacturing***Description**

The Oxide data frame has 72 rows and 5 columns.

**Format**

This data frame contains the following columns:

**Source** a factor with levels 1 and 2

**Lot** a factor giving a unique identifier for each lot.

**Wafer** a factor giving a unique identifier for each wafer within a lot.

**Site** a factor with levels 1, 2, and 3

**Thickness** a numeric vector giving the thickness of the oxide layer.

## Details

These data are described in Littell et al. (1996, p. 155) as coming “from a passive data collection study in the semiconductor industry where the objective is to estimate the variance components to determine the assignable causes of the observed variability.” The observed response is the thickness of the oxide layer on silicon wafers, measured at three different sites of each of three wafers selected from each of eight lots sampled from the population of lots.

|                   |                                         |
|-------------------|-----------------------------------------|
| pairs.compareFits | <i>Pairs Plot of compareFits Object</i> |
|-------------------|-----------------------------------------|

---

## Description

Scatter plots of the values being compared are generated for each pair of coefficients in `x`. Different symbols (colors) are used for each object being compared and values corresponding to the same group are joined by a line, to facilitate comparison of fits. If only two coefficients are present, the trellis function `xypplot` is used; otherwise the trellis function `splo` is used.

## Usage

```
S3 method for class 'compareFits'
pairs(x, subset, key, ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | an object of class <code>compareFits</code> .                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>subset</code> | an optional logical or integer vector specifying which rows of <code>x</code> should be used in the plots. If missing, all rows are used.                                                                                                                                                                                                                                                                                          |
| <code>key</code>    | an optional logical value, or list. If <code>TRUE</code> , a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If <code>FALSE</code> , no legend is included. If given as a list, <code>key</code> is passed down as an argument to the trellis function generating the plots ( <code>splo</code> or <code>xypplot</code> ). Defaults to <code>TRUE</code> . |
| <code>...</code>    | optional arguments passed down to the trellis function generating the plots.                                                                                                                                                                                                                                                                                                                                                       |

## Value

Pairwise scatter plots of the values being compared, with different symbols (colors) used for each object under comparison.

|------------------------|------------------------------------|
| <code>pairs.lme</code> | <i>Pairs Plot of an lme Object</i> |
|------------------------|------------------------------------|

---

**Description**

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a `|` operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function `xyplot` is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function `splom` is used).

**Usage**

```
S3 method for class 'lme'
pairs(x, form, label, id, idLabels, grid, ...)
```

**Arguments**

- `x` an object inheriting from class `"lme"`, representing a fitted linear mixed-effects model.
- `form` an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `x` can be referenced. In addition, `x` itself can be referenced in the formula using the symbol `"."`. Conditional expressions on the right of a `|` operator can be used to define separate panels in a Trellis display. The expression on the right hand side of `form`, and to the left of the `|` operator, must evaluate to a data frame with at least two columns. Default is `~ coef(.)`, corresponding to a pairs plot of the coefficients evaluated at the innermost level of nesting.
- `label` an optional character vector of labels for the variables in the pairs plot.
- `id` an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the  $1 - \text{value}$  percentile of the appropriate chi-square distribution are identified in the plot using `idLabels`. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.

|          |                                                                                                                                                                                                                                                                                                                                                         |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| idLabels | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor. |
| grid     | an optional logical value indicating whether a grid should be added to plot. Default is FALSE.                                                                                                                                                                                                                                                          |
| ...      | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                 |

**Value**

a diagnostic Trellis plot.

The expression on the right hand side of <code>form</code> , and to the left of the <code> </code> operator, must evaluate to a data frame with at least two columns. Default is <code>~coef(.)</code> , corresponding to a pairs plot of the coefficients of <code>x</code> . |
| <code>label</code>    | an optional character vector of labels for the variables in the pairs plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>id</code>       | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the $1 - \text{value}$ percentile of the appropriate chi-square distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.                                                                                               |
| <code>idLabels</code> | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor.                                                                                                                                                                                                                                                                                                                    |
| <code>grid</code>     | an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>...</code>      | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

PBG

*Effect of Phenylbiguanide on Blood Pressure***Description**

The PBG data frame has 60 rows and 5 columns.

**Format**

This data frame contains the following columns:

**deltaBP** a numeric vector

**dose** a numeric vector

**Run** an ordered factor with levels T5 < T4 < T3 < T2 < T1 < P5 < P3 < P2 < P4 < P1

**Treatment** a factor with levels MDL 72222 Placebo

**Rabbit** an ordered factor with levels 5 < 3 < 2 < 4 < 1

**Details**

Data on an experiment to examine the effect of a antagonist MDL 72222 on the change in blood pressure experienced with increasing dosage of phenylbiguanide are described in Ludbrook (1994) and analyzed in Venables and Ripley (2002, section 10.3). Each of five rabbits was exposed to increasing doses of phenylbiguanide after having either a placebo or the HD5-antagonist MDL 72222 administered.

pdBlocked

*Positive-Definite Block Diagonal Matrix***Description**

This function is a constructor for the pdBlocked class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual pdMat object. When value is numeric(0), a list of uninitialized pdMat objects, a list of one-sided formulas, or a list of vectors of character strings, object is returned as an uninitialized pdBlocked object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is a list of initialized pdMat objects, object will be constructed from the list obtained by applying as.matrix to each of the pdMat elements of value. Finally, if value is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

**Usage**

```
pdBlocked(value, form, nam, data, pdClass)
```

**Arguments**

|         |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value   | an optional list with elements to be used as the value argument to other pdMat constructors. These include: pdMat objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object. |
| form    | an optional list of one-sided linear formulas specifying the row/column names for the block-diagonal elements of the matrix represented by object. Because factors may be present in form, the formulas needs to be evaluated on a data.frame to resolve the names they define. This argument is ignored when value is a list of one-sided formulas. Defaults to NULL.                                              |
| nam     | an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by object. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when value is a list of vector of character strings. Defaults to NULL.                          |
| data    | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on any factors appearing in the formulas. Defaults to the parent frame from which the function was called.                                         |
| pdClass | an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".                                                                                  |

**Value**

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

pd1 <- pdBlocked(list(diag(1:2), diag(c(0.1, 0.2, 0.3))),
 nam = list(c("A", "B"), c("a1", "a2", "a3")))
pd1
```

pdClasses

*Positive-Definite Matrix Classes***Description**

Standard classes of positive-definite matrices (pdMat) available in the **nlme** package.

**Value**

Available standard classes:

|            |                                                                                                                                                                                                                                        |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pdSymm     | general positive-definite matrix, with no additional structure                                                                                                                                                                         |
| pdLogChol  | general positive-definite matrix, with no additional structure, using a log-Cholesky parameterization                                                                                                                                  |
| pdDiag     | diagonal                                                                                                                                                                                                                               |
| pdIdent    | multiple of an identity                                                                                                                                                                                                                |
| pdCompSymm | compound symmetry structure (constant diagonal and constant off-diagonal elements)                                                                                                                                                     |
| pdBlocked  | block-diagonal matrix, with diagonal blocks of any "atomic" pdMat class                                                                                                                                                                |
| pdNatural  | general positive-definite matrix in natural parametrization (i.e. parametrized in terms of standard deviations and correlations). The underlying coefficients are not unrestricted, so this class should NOT be used for optimization. |

**Note**

Users may define their own pdMat classes by specifying a constructor function and, at a minimum, methods for the functions [pdConstruct](#), [pdMatrix](#), and [coef](#). For examples of these functions, see the methods for classes pdSymm and pdDiag.

pdCompSymm

*Positive-Definite Matrix with Compound Symmetry Structure***Description**

This function is a constructor for the `pdCompSymm` class, representing a positive-definite matrix with compound symmetry structure (constant diagonal and constant off-diagonal elements). The underlying matrix is represented by 2 unrestricted parameters. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized `pdCompSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, object will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector of length 2, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

**Usage**

```
pdCompSymm(value, form, nam, data)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector of length 2. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.                                                          |
| <code>form</code>  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .                                        |
| <code>nam</code>   | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .                                                                |
| <code>data</code>  | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

**Value**

a `pdCompSymm` object representing a positive-definite matrix with compound symmetry structure, also inheriting from class `pdMat`.

pdConstruct

*Construct pdMat Objects*

---

**Description**

This function is an alternative constructor for the `pdMat` class associated with object and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the `pdMat` class of object.

**Usage**

```
pdConstruct(object, value, form, nam, data, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>pdMat</code> , representing a positive definite matrix.                                                                                                                                                                                                                                                                                                                    |
| <code>value</code>  | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.                                                                      |
| <code>form</code>   | an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .                          |
| <code>nam</code>    | an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .                                                  |
| <code>data</code>   | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| <code>...</code>    | optional arguments for some methods.                                                                                                                                                                                                                                                                                                                                                                             |

**Value**

a `pdMat` object representing a positive-definite matrix, inheriting from the same classes as `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
pd1 <- pdSymm()
pdConstruct(pd1, diag(1:4))
```

---

pdConstruct.pdBlocked    *Construct pdBlocked Objects*

---

**Description**

This function give an alternative constructor for the pdBlocked class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual pdMat object. When value is numeric(0), a list of uninitialized pdMat objects, a list of one-sided formulas, or a list of vectors of character strings, object is returned as an uninitialized pdBlocked object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is a list of initialized pdMat objects, object will be constructed from the list obtained by applying as.matrix to each of the pdMat elements of value. Finally, if value is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

**Usage**

```
S3 method for class 'pdBlocked'
pdConstruct(object, value, form, nam, data, pdClass,
...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class "pdBlocked", representing a positive definite block-diagonal matrix.                                                                                                                                                                                                                                                                                                  |
| value  | an optional list with elements to be used as the value argument to other pdMat constructors. These include: pdMat objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to numeric(0), corresponding to an uninitialized object. |
| form   | an optional list of one-sided linear formula specifying the row/column names for the block-diagonal elements of the matrix represented by object. Because factors may be present in form, the formulas needs to be evaluated on a data.frame to resolve the names they defines. This argument is ignored when value is a list of one-sided formulas. Defaults to NULL.                                |
| nam    | an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by object. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when value is a list of vector of character strings. Defaults to NULL.            |

|         |                                                                                                                                                                                                                                                                                                                                                                         |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data    | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| pdClass | an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".                                      |
| ...     | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                               |

### Value

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

### Examples

```
pd1 <- pdBlocked(list(c("A","B"), c("a1", "a2", "a3")))
pdConstruct(pd1, list(diag(1:2), diag(c(0.1, 0.2, 0.3))))
```

---

pdDiag

*Diagonal Positive-Definite Matrix*

---

### Description

This function is a constructor for the pdDiag class, representing a diagonal positive-definite matrix. If the matrix associated with object is of dimension  $n$ , it is represented by  $n$  unrestricted parameters, given by the logarithm of the square-root of the diagonal values. When value is `numeric(0)`, an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdDiag object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If value is an initialized pdMat object, object will be constructed from `as.matrix(value)`. Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

### Usage

```
pdDiag(value, form, nam, data)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector of length equal to the dimension of the underlying positive-definite matrix. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object. |
| form  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.                                                                          |
| nam   | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.                                                                       |
| data  | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.                      |

**Value**

pd1
```

---

pdFactor

*Square-Root Factor of a Positive-Definite Matrix*

---

**Description**

A square-root factor of the positive-definite matrix represented by object is obtained. Letting  $\Sigma$  denote a positive-definite matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This function extracts  $L$ .

**Usage**

```
pdFactor(object)
```

**Arguments**

**object** an object inheriting from class `pdMat`, representing a positive definite matrix, which must have been initialized (i.e. `length(coef(object)) > 0`).

**Value**

a vector with a square-root factor of the positive-definite matrix associated with `object` stacked column-wise.

**Note**

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `pdMatrix` function can be used to obtain square-root factors in matrix form.

pdIdent

*Multiple of the Identity Positive-Definite Matrix*

---

**Description**

This function is a constructor for the `pdIdent` class, representing a multiple of the identity positive-definite matrix. The matrix associated with object is represented by 1 unrestricted parameter, given by the logarithm of the square-root of the diagonal value. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized `pdIdent` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, object will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric value, it is assumed to represent the unrestricted coefficient of the underlying positive-definite matrix.

**Usage**

```
pdIdent(value, form, nam, data)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                                         |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric value. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.                                                         |
| form  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.                                                     |
| nam   | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.                                                  |
| data  | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

**Value**

a pdIdent object representing a multiple of the identity positive-definite matrix, also inheriting from class pdMat.

pd1
```

## Description

This function is a constructor for the `pdLogChol` class, representing a general positive-definite matrix. If the matrix associated with `object` is of dimension  $n$ , it is represented by  $n(n + 1)/2$  unrestricted parameters, using the log-Cholesky parametrization described in Pinheiro and Bates (1996).

- When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a character vector, `object` is returned as an *uninitialized* `pdLogChol` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions.
- If `value` is an *initialized* `pdMat` object, `object` will be constructed from `as.matrix(value)`.
- Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

## Usage

```
pdLogChol(value, form, nam, data)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.                                                                      |
| <code>form</code>  | an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a data frame to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .                                       |
| <code>nam</code>   | an optional character vector specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a character vector. Defaults to <code>NULL</code> .                                                                        |
| <code>data</code>  | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

## Details

Internally, the `pdLogChol` representation of a symmetric positive definite matrix is a vector starting with the logarithms of the diagonal of the Choleski factorization of that matrix followed by its upper triangular portion.

## Value

a `pdLogChol` object representing a general positive-definite matrix, also inheriting from class `pdMat`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Description

This function gives an alternative way of constructing an object inheriting from the `pdMat` class named in `pdClass`, or from `data.class(object)` if object inherits from `pdMat`, and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the `pdMat` class of object.

## Usage

```
pdMat(value, form, nam, data, pdClass)
```

## Arguments

- |       |                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.                                                         |
| form  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to <code>NULL</code> .                                        |
| nam   | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to <code>NULL</code> .                                                  |
| data  | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

**pdClass** an optional character string naming the pdMat class to be assigned to the returned object. This argument will only be used when value is not a pdMat object. Defaults to "pdSymm".

### Value

a pdMat object representing a positive-definite matrix, inheriting from the class named in pdClass, or from class(object), if object inherits from pdMat.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

### Examples

```
pd1 <- pdMat(diag(1:4), pdClass = "pdDiag")
pd1
str(pd1)
```

---

pdMatrix

*Extract Matrix or Square-Root Factor from a pdMat Object*

---

### Description

The positive-definite matrix represented by object, or a square-root factor of it is obtained. Letting  $\Sigma$  denote a positive-definite matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This function extracts  $\Sigma$  or  $L$ .

### Usage

```
pdMatrix(object, factor)
```

### Arguments

**object** an object inheriting from class pdMat, representing a positive definite matrix.

**factor** an optional logical value. If TRUE, a square-root factor of the positive-definite matrix represented by object is returned; else, if FALSE, the positive-definite matrix is returned. Defaults to FALSE.

### Value

if factor is FALSE the positive-definite matrix represented by object is returned; else a square-root of the positive-definite matrix is returned.

|                   |                                                                                   |
|-------------------|-----------------------------------------------------------------------------------|
| pdMatrix.reStruct | <i>Extract Matrix or Square-Root Factor from Components of an reStruct Object</i> |
|-------------------|-----------------------------------------------------------------------------------|

---

**Description**

This method function extracts the positive-definite matrices corresponding to the pdMat elements of object, or square-root factors of the positive-definite matrices.

**Usage**

```
S3 method for class 'reStruct'
pdMatrix(object, factor)
```

**Arguments**

|        |                                                                                                                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of pdMat objects.                                                                              |
| factor | an optional logical value. If TRUE, square-root factors of the positive-definite matrices represented by the elements of object are returned; else, if FALSE, the positive-definite matrices are returned. Defaults to FALSE. |

**Value**

a list with components given by the positive-definite matrices corresponding to the elements of object, or square-root factors of the positive-definite matrices.

|-----------|--------------------------------------------------------------------|
| pdNatural | <i>General Positive-Definite Matrix in Natural Parametrization</i> |
|-----------|--------------------------------------------------------------------|

---

Description

This function is a constructor for the `pdNatural` class, representing a general positive-definite matrix, using a natural parametrization . If the matrix associated with object is of dimension  $n$ , it is represented by  $n(n+1)/2$  parameters. Letting  $\sigma_{ij}$  denote the  $ij$ -th element of the underlying positive definite matrix and  $\rho_{ij} = \sigma_i / \sqrt{\sigma_{ii}\sigma_{jj}}$ ,  $i \neq j$  denote the associated "correlations", the "natural" parameters are given by  $\sqrt{\sigma_{ii}}$ ,  $i = 1, \dots, n$  and  $\log((1 + \rho_{ij})/(1 - \rho_{ij}))$ ,  $i \neq j$ . Note that all natural parameters are individually unrestricted, but not jointly unrestricted (meaning that not all unrestricted vectors would give positive-definite matrices). Therefore, this parametrization should NOT be used for optimization. It is mostly used for deriving approximate confidence intervals on parameters following the optimization of an objective function. When value is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized `pdSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If value is an initialized `pdMat` object, object will be constructed from `as.matrix(value)`. Finally, if value is a numeric vector, it is assumed to represent the natural parameters of the underlying positive-definite matrix.

Usage

```
pdNatural(value, form, nam, data)
```

Arguments

|       |                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.                                           |
| form  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to <code>NULL</code> .                                        |
| nam   | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to <code>NULL</code> .                                                  |
| data  | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

**Value**

a pdNatural object representing a general positive-definite matrix in natural parametrization, also inheriting from class pdMat.

pdSymm

*General Positive-Definite Matrix*

---

**Description**

This function is a constructor for the pdSymm class, representing a general positive-definite matrix. If the matrix associated with object is of dimension  $n$ , it is represented by  $n(n + 1)/2$  unrestricted parameters, using the matrix-logarithm parametrization described in Pinheiro and Bates (1996). When value is `numeric(0)`, an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdSymm object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If value is an initialized pdMat object, object will be constructed from `as.matrix(value)`. Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

**Usage**

```
pdSymm(value, form, nam, data)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                     |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.    |
| form  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL. |

- nam** an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.
- data** an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Value

a pdSymm object representing a general positive-definite matrix, also inheriting from class pdMat.

|-----------|-------------------------------|
| Phenobarb | <i>Phenobarbital Kinetics</i> |
|-----------|-------------------------------|

---

Description

The Phenobarb data frame has 744 rows and 7 columns.

Format

- This data frame contains the following columns:
- Subject** an ordered factor identifying the infant.
  - Wt** a numeric vector giving the birth weight of the infant (kg).
  - Apgar** an ordered factor giving the 5-minute Apgar score for the infant. This is an indication of health of the newborn infant.
  - ApgarInd** a factor indicating whether the 5-minute Apgar score is < 5 or >= 5.
  - time** a numeric vector giving the time when the sample is drawn or drug administered (hr).
  - dose** a numeric vector giving the dose of drug administered (ug/kg).
  - conc** a numeric vector giving the phenobarbital concentration in the serum (ug/L).

## Details

Data from a pharmacokinetics study of phenobarbital in neonatal infants. During the first few days of life the infants receive multiple doses of phenobarbital for prevention of seizures. At irregular intervals blood samples are drawn and serum phenobarbital concentrations are determined. The data were originally given in Grasela and Donn(1985) and are analyzed in Boeckmann, Sheiner and Beal (1994), in Davidian and Giltinan (1995), and in Littell et al. (1996).

phenoModel

*Model function for the Phenobarb data*

---

## Description

A model function for a model used with the Phenobarb data. This function uses compiled C code to improve execution speed.

## Usage

```
phenoModel(Subject, time, dose, lCl, lV)
```

## Arguments

|         |                                                                                                                       |
|---------|-----------------------------------------------------------------------------------------------------------------------|
| Subject | an integer vector of subject identifiers. These should be sorted in increasing order.                                 |
| time    | numeric. A vector of the times at which the sample was drawn or the drug administered (hr).                           |
| dose    | numeric. A vector of doses of drug administered (ug/kg).                                                              |
| lCl     | numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.              |
| lV      | numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time. |

## Details

See the details section of [Phenobarb](#) for a description of the model function that phenoModel evaluates.

**Value**

a numeric vector of predicted phenobarbital concentrations.

|-------|------------------------------------------|
| Pixel | <i>X-ray pixel intensities over time</i> |
|-------|------------------------------------------|

---

**Description**

The Pixel data frame has 102 rows and 4 columns of data on the pixel intensities of CT scans of dogs over time

**Format**

This data frame contains the following columns:

**Dog** a factor with levels 1 to 10 designating the dog on which the scan was made

**Side** a factor with levels L and R designating the side of the dog being scanned

**day** a numeric vector giving the day post injection of the contrast on which the scan was made

**pixel** a numeric vector of pixel intensities

**Source**

Pinheiro, J. C. and Bates, D. M. (2000) *Mixed-effects Models in S and S-PLUS*, Springer.

**Examples**

```
fm1 <- lme(pixel ~ day + I(day^2), data = Pixel,
 random = list(Dog = ~ day, Side = ~ 1))
summary(fm1)
VarCorr(fm1)
```

---

plot.ACF*Plot an ACF Object*

---

**Description**

an xyplot of the autocorrelations versus the lags, with `type = "h"`, is produced. If  $\alpha > 0$ , curves representing the critical limits for a two-sided test of level  $\alpha$  for the autocorrelations are added to the plot.

**Usage**

```
S3 method for class 'ACF'
plot(x, alpha, xlab, ylab, grid, ...)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | an object inheriting from class <code>ACF</code> , consisting of a data frame with two columns named <code>lag</code> and <code>ACF</code> , representing the autocorrelation values and the corresponding lags.                                                     |
| <code>alpha</code>      | an optional numeric value with the significance level for testing if the autocorrelations are zero. Lines corresponding to the lower and upper critical values for a test of level $\alpha$ are added to the plot. Default is 0, in which case no lines are plotted. |
| <code>xlab, ylab</code> | optional character strings with the x- and y-axis labels. Default respectively to "Lag" and "Autocorrelation".                                                                                                                                                       |
| <code>grid</code>       | an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .                                                                                                                                                         |
| <code>...</code>        | optional arguments passed to the <code>xyplot</code> function.                                                                                                                                                                                                       |

**Value**

an xyplot Trellis plot.

**Author(s)**

**Examples**

```
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(ACF(fm1, maxLag = 10), alpha = 0.01)
```

---

`plot.augPred`*Plot an augPred Object*

---

### Description

A Trellis xyplot of predictions versus the primary covariate is generated, with a different panel for each value of the grouping factor. Predicted values are joined by lines, with different line types (colors) being used for each level of grouping. Original observations are represented by circles.

### Usage

```
S3 method for class 'augPred'
plot(x, key, grid, ...)
```

### Arguments

|                   |                                                                                                                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | an object of class " <a href="#">augPred</a> ".                                                                                                                                                                                                                                                                                                |
| <code>key</code>  | an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the <code>trellis</code> function generating the plots (xyplot). Defaults to TRUE. |
| <code>grid</code> | an optional logical value indicating whether a grid should be added to plot. Default is FALSE.                                                                                                                                                                                                                                                 |
| <code>...</code>  | optional arguments passed down to the <code>trellis</code> function generating the plots.                                                                                                                                                                                                                                                      |

### Value

A Trellis plot of predictions versus the primary covariate, with panels determined by the grouping factor.

plot.gls

*Plot a gls Object***Description**

Diagnostic plots for the linear model fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

**Usage**

```
S3 method for class 'gls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object inheriting from class <code>"gls"</code> , representing a generalized least squares fitted linear model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>form</code>      | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "p") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting. |
| <code>abline</code>    | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.                                                                                                                                                                                                                                                                             |
| <code>id</code>        | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.        |
| <code>idLabels</code>  | an optional vector, or one-sided formula. If given as a vector, it is converted to character mode and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character mode and used to label the identified observations. Default is the innermost grouping factor.                                                                                                                                                                                              |
| <code>idResType</code> | an optional character string specifying the type of residuals to be used in identifying outliers, when <code>id</code> is a numeric value. If <code>"pearson"</code> , the standardized                                                                                                                                                                                                                                                                                                                                                                                                  |

residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

`grid` an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if `xyplot` defaults to TRUE, else defaults to FALSE.

`...` optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot.

standardized residuals versus fitted values by Mare
plot(fm1, resid(., type = "p") ~ fitted(.) | Mare, abline = 0)
box-plots of residuals by Mare
plot(fm1, Mare ~ resid(.))
observed versus fitted values by Mare
plot(fm1, follicles ~ fitted(.) | Mare, abline = c(0,1))
```

---

`plot.intervals.lmList` *Plot lmList Confidence Intervals*

---

**Description**

A Trellis dot-plot of the confidence intervals on the linear model coefficients is generated, with a different panel for each coefficient. Rows in the dot-plot correspond to the names of the `lm` components of the `lmList` object used to produce `x`. The lower and upper confidence limits are connected by a line segment and the estimated coefficients are marked with a "+".

This is based on function `dotplot()` from package **lattice**.

**Usage**

```
S3 method for class 'intervals.lmList'
plot(x, xlab = "", ylab = attr(x, "groupName"),
 strip = function(...) strip.default(..., style = 1),
 ...)
```

Arguments

|            |                                                                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x          | an object inheriting from class " <a href="#">intervals.lmList</a> ", representing confidence intervals and estimates for the coefficients in the lm components of the lmList object used to produce x. |
| xlab, ylab | axis labels, each with a sensible default.                                                                                                                                                              |
| strip      | a <a href="#">function</a> or FALSE, see <a href="#">dotplot()</a> from package <a href="#">lattice</a> .                                                                                               |
| ...        | optional arguments passed to the dotplot function (see above).                                                                                                                                          |

Value

a Trellis plot with the confidence intervals on the coefficients of the individual lm components of the lmList that generated x.

Description

Diagnostic plots for the linear mixed-effects fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If form is a one-sided formula, histograms of the variable on the right hand side of the formula, before a | operator, are displayed (the Trellis function histogram is used). If form is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function xyplot is used). Finally, if form is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function bwplot is used).

Usage

```
S3 method for class 'lme'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
S3 method for class 'nls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object inheriting from class <code>"lme"</code> , representing a fitted linear mixed-effects model, or from <code>nls</code> , representing an fitted nonlinear least squares model.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>form</code>      | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "p") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.                      |
| <code>abline</code>    | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.                                                                                                                                                                                                                                                                                                  |
| <code>id</code>        | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized, or normalized residuals. Observations with absolute standardized (normalized) residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified. |
| <code>idLabels</code>  | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.                                                                                                                                                                                                                             |
| <code>idResType</code> | an optional character string specifying the type of residuals to be used in identifying outliers, when <code>id</code> is a numeric value. If <code>"pearson"</code> , the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if <code>"normalized"</code> , the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"pearson"</code> .            |
| <code>grid</code>      | an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xypLOT</code> defaults to <code>TRUE</code> , else defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>...</code>       | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Value**

a diagnostic Trellis plot.

## Description

Diagnostic plots for the linear model fits corresponding to the  $x$  components are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

## Usage

```
S3 method for class 'lmList'
plot(x, form, abline, id, idLabels, grid, ...)
```

## Arguments

- |                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | an object inheriting from class " <code>lmList</code> ", representing a list of <code>lm</code> objects with a common model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>form</code>   | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "pool") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals (using a pooled estimate for the residual standard error) versus fitted values. |
| <code>abline</code> | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.                                                                                                                                                                                                                                                                                        |
| <code>id</code>     | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.                   |

|          |                                                                                                                                                                                                                                                                                                                                                                  |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| idLabels | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is <code>getGroups(x)</code> . |
| grid     | an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xyplot</code> defaults to <code>TRUE</code> , else defaults to <code>FALSE</code> .                                                                                                                                      |
| ...      | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                          |

**Value**

**Description**

A Trellis dot-plot of the response by group is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. The Trellis function `dotplot` is used.

**Usage**

```
S3 method for class 'nffGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, panel, key,
 grid, ...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | an object inheriting from class <code>nffGroupedData</code> , representing a <code>groupedData</code> object with a factor primary covariate and a single grouping level.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>outer</code>       | an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used. |
| <code>inner</code>       | an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "inner")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.                                                                                                                        |
| <code>innerGroups</code> | an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or symbols, are used for each level of the <code>innerGroups</code> factor. Default is <code>NULL</code> , meaning that no <code>innerGroups</code> covariate is present.                                                                                                                                                                                                                                                                                   |
| <code>xlab</code>        | an optional character string with the label for the horizontal axis. Default is the <code>y</code> elements of <code>attr(object, "labels")</code> and <code>attr(object, "units")</code> pasted together.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>ylab</code>        | an optional character string with the label for the vertical axis. Default is the grouping factor name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>strip</code>       | an optional function passed as the <code>strip</code> argument to the <code>dotplot</code> function. Default is <code>strip.default(..., style = 1)</code> (see <code>trellis.args</code> ).                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>panel</code>       | an optional function used to generate the individual panels in the Trellis display, passed as the <code>panel</code> argument to the <code>dotplot</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>key</code>         | an optional logical function or function. If <code>TRUE</code> and either <code>inner</code> or <code>innerGroups</code> are non- <code>NULL</code> , a legend for the different inner ( <code>innerGroups</code> ) levels is included at the top of the plot. If given as a function, it is passed as the <code>key</code> argument to the <code>dotplot</code> function. Default is <code>TRUE</code> if either <code>inner</code> or <code>innerGroups</code> are non- <code>NULL</code> and <code>FALSE</code> otherwise.                                                              |
| <code>grid</code>        | this argument is included for consistency with the <code>plot.nfnGroupedData</code> method calling sequence. It is ignored in this method function.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>...</code>         | optional arguments passed to the <code>dotplot</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Value**

a Trellis dot-plot of the response by group.

**Author(s)**

**Examples**

```
plot(Machines)
plot(Machines, inner = TRUE)
```

---

`plot.nfnGroupedData`     *Plot an nfnGroupedData Object*

---

**Description**

A Trellis plot of the response versus the primary covariate is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. Otherwise, the levels of the grouping variable determine the panels. A scatter plot of the response versus the primary covariate is displayed in each panel, with observations corresponding to same inner group joined by line segments. The Trellis function `xyplot` is used.

**Usage**

```
S3 method for class 'nfnGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, aspect, panel,
 key, grid, ...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | an object inheriting from class <code>nfnGroupedData</code> , representing a <code>groupedData</code> object with a numeric primary covariate and a single grouping level.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>outer</code>       | an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used. |
| <code>inner</code>       | an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "inner")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.                                                                                                                        |
| <code>innerGroups</code> | an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or line types, are used for each level of the <code>innerGroups</code> factor. Default is <code>NULL</code> , meaning that no <code>innerGroups</code> covariate is present.                                                                                                                                                                                                                                                                                |
| <code>xlab, ylab</code>  | optional character strings with the labels for the plot. Default is the corresponding elements of <code>attr(object, "labels")</code> and <code>attr(object, "units")</code> pasted together.                                                                                                                                                                                                                                                                                                                                                                                              |

|        |                                                                                                                                                                                                                                                                                                                   |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| strip  | an optional function passed as the strip argument to the xyplot function. Default is strip.default(..., style = 1) (see trellis.args).                                                                                                                                                                            |
| aspect | an optional character string indicating the aspect ratio for the plot passed as the aspect argument to the xyplot function. Default is "xy" (see trellis.args).                                                                                                                                                   |
| panel  | an optional function used to generate the individual panels in the Trellis display, passed as the panel argument to the xyplot function.                                                                                                                                                                          |
| key    | an optional logical function or function. If TRUE and innerGroups is non-NULL, a legend for the different innerGroups levels is included at the top of the plot. If given as a function, it is passed as the key argument to the xyplot function. Default is TRUE if innerGroups is non-NULL and FALSE otherwise. |
| grid   | an optional logical value indicating whether a grid should be added to plot. Default is TRUE.                                                                                                                                                                                                                     |
| ...    | optional arguments passed to the xyplot function.                                                                                                                                                                                                                                                                 |

**Value**

a Trellis plot of the response versus the primary covariate.

**Author(s)**

```
different panels per Subject
plot(Orthodont)
different panels per gender
plot(Orthodont, outer = TRUE)
```

---

plot.nmGroupedData      *Plot an nmGroupedData Object*

---

**Description**

The groupedData object is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor, which is plotted using the appropriate plot method for groupedData objects with single level of grouping.

**Usage**

```
S3 method for class 'nmGroupedData'
plot(x, collapseLevel, displayLevel, outer, inner,
 preserve, FUN, subset, key, grid, ...)
```

**Arguments**

- |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x             | an object inheriting from class <code>nmGroupedData</code> , representing a <code>groupedData</code> object with multiple grouping factors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| collapseLevel | an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| displayLevel  | an optional positive integer or character string indicating the grouping level to use for determining the panels in the Trellis display, when <code>outer</code> is missing. Default is <code>collapseLevel</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| outer         | an optional logical value or one-sided formula, indicating covariates that are outer to the <code>displayLevel</code> grouping factor, which are used to determine the panels of the Trellis plot. If equal to <code>TRUE</code> , the <code>displayLevel</code> element <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| inner         | an optional logical value or one-sided formula, indicating a covariate that is inner to the <code>displayLevel</code> grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| preserve      | an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the <code>collapseLevel</code> grouping factor. The collapsing factor is obtained by pasting together the levels of the <code>collapseLevel</code> grouping factor and the values of the covariate to be preserved. Default is <code>NULL</code> , meaning that no covariates need to be preserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| FUN           | an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by <code>collapseLevel</code> . Invariant variables are always summarized by group using the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the data such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| subset        | an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be used for plotting the data. Default is <code>NULL</code> , meaning that all levels are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|      |                                                                                                                                                                                                                                                                                                                                                               |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| key  | an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the <code>trellis</code> function generating the plots ( <code>xyplot</code> ). Defaults to TRUE. |
| grid | an optional logical value indicating whether a grid should be added to plot. Default is TRUE.                                                                                                                                                                                                                                                                 |
| ...  | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                       |

### Value

a Trellis display of the data collapsed over the values of the `collapseLevel` grouping factor and grouped according to the `displayLevel` grouping factor.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### Examples

```
no collapsing, panels by Dog
plot(Pixel, displayLevel = "Dog", inner = ~Side)
collapsing by Dog, preserving day
plot(Pixel, collapseLevel = "Dog", preserve = ~day)
```

---

plot.ranef.lme

*Plot a ranef.lme Object*

---

### Description

Plots (class "Trellis" from package **lattice**) of the random effects from linear mixed effects model, i.e., the result of `ranef(lme(*))` (of class "`ranef.lme`").

### Usage

```
S3 method for class 'ranef.lme'
plot(x, form = NULL, omitFixed = TRUE, level = Q,
 grid = TRUE, control, xlab, ylab, strip,
 ...)
```

**Arguments**

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x          | an object inheriting from class " <code>ranef.lme</code> ", representing the estimated coefficients or estimated random effects for the <code>lme</code> object from which it was produced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| form       | an optional formula specifying the desired type of plot. <ul style="list-style-type: none"> <li>• If given as a one-sided formula, a <code>dotplot()</code> of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in <code>form</code> is returned.</li> <li>• If given as a two-sided formula (or by default, <code>NULL</code>), an <code>xyplot()</code> Trellis display of the random effect (coefficient) versus the named covariates is returned. In <code>NULL</code> case the row names of the random effects (coefficients) are used (as covariates).</li> </ul> See also 'Details:'.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| omitFixed  | an optional logical value indicating whether columns with values that are constant across groups should be omitted. Default is <code>TRUE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| level      | an optional integer value giving the level of grouping to be used for <code>x</code> . Only used when <code>x</code> is a list with different components for each grouping level. Defaults to the highest or innermost level of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| grid       | an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in <code>form</code> . Default is <code>TRUE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| control    | an optional list with control values for the plot, when <code>form</code> is given as a two-sided formula. The control values are referenced by name in the <code>control</code> list and only the ones to be modified from the default need to be specified. Available values include: <code>drawLine</code> , a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is <code>TRUE</code> ); <code>span.loess</code> , used as the <code>span</code> argument in the call to <code>panel.loess</code> (default is <code>2/3</code> ); <code>degree.loess</code> , used as the <code>degree</code> argument in the call to <code>panel.loess</code> (default is <code>1</code> ); <code>cex.axis</code> , the character expansion factor for the x-axis (default is <code>0.8</code> ); <code>srt.axis</code> , the rotation factor for the x-axis (default is <code>0</code> ); and <code>mgp.axis</code> , the margin parameters for the x-axis (default is <code>c(2, 0.5, 0)</code> ). |
| xlab, ylab | axis labels, each with a sensible default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Details**

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot (via `dotplot()` from pkg **`lattice`**) of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). Single factors (`~g`) or crossed factors (`~g1*g2`) are allowed. For a single factor, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula.

If `form` is a two-sided formula, the left hand side must be a single random effect (coefficient) and the right hand side is formed by covariates in `x` separated by `+`. An `xyplot()` Trellis display is generated, with a different panel for each variable listed in the right hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (factor or ordered) variables.

**Value**

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

**Description**

If form is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the form argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in form, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if form specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function dotplot is used in this method function.

If form is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of form. Scatter plots are generated for numeric variables and boxplots are generated for categorical (factor or ordered) variables.

**Usage**

```
S3 method for class 'ranef.lmList'
plot(x, form, grid, control, ...)
```

**Arguments**

|      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x    | an object inheriting from class " <a href="#">ranef.lmList</a> ", representing the estimated coefficients or estimated random effects for the lmList object from which it was produced.                                                                                                                                                                                                                                                                                                        |
| form | an optional formula specifying the desired type of plot. If given as a one-sided formula, a dotplot of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in form is returned. Single factors (~g) or crossed factors (~g1*g2) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in x separated by +. A Trellis |

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|         | display of the random effect (coefficient) versus the named covariates is returned in this case. Default is NULL, in which case the row names of the random effects (coefficients) are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| grid    | an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in form. Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| control | an optional list with control values for the plot, when form is given as a two-sided formula. The control values are referenced by name in the control list and only the ones to be modified from the default need to be specified. Available values include: drawLine, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is TRUE); span.loess, used as the span argument in the call to panel.loess (default is 2/3); degree.loess, used as the degree argument in the call to panel.loess (default is 1); cex.axis, the character expansion factor for the x-axis (default is 0.8); srt.axis, the rotation factor for the x-axis (default is 0); and mgp.axis, the margin parameters for the x-axis (default is c(2, 0.5, 0)). |
| ...     | optional arguments passed to the Trellis dotplot function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Value**

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lmList](#), [dotplot](#)

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
plot(ranef(fm1))
fm1RE <- ranef(fm1, augFrame = TRUE)
plot(fm1RE, form = ~ Sex)
plot(fm1RE, form = age ~ Sex)
```

---

plot.Variogram

---

*Plot a Variogram Object*

---

**Description**

an xyplot of the semi-variogram versus the distances is produced. If smooth = TRUE, a loess smoother is added to the plot. If showModel = TRUE and x includes an "modelVariog" attribute, the corresponding semi-variogram is added to the plot.

**Usage**

```
S3 method for class 'Variogram'
plot(x, smooth, showModel, sigma, span, xlab,
 ylab, type, ylim, grid, ...)
```

Arguments

|            |                                                                                                                                                                                                                                   |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x          | an object inheriting from class " <a href="#">Variogram</a> ", consisting of a data frame with two columns named variog and dist, representing the semi-variogram values and the corresponding distances.                         |
| smooth     | an optional logical value controlling whether a loess smoother should be added to the plot. Defaults to TRUE, when showModel is FALSE.                                                                                            |
| showModel  | an optional logical value controlling whether the semi-variogram corresponding to an "modelVariog" attribute of x, if any is present, should be added to the plot. Defaults to TRUE, when the "modelVariog" attribute is present. |
| sigma      | an optional numeric value used as the height of a horizontal line displayed in the plot. Can be used to represent the process standard deviation. Default is NULL, implying that no horizontal line is drawn.                     |
| span       | an optional numeric value with the smoothing parameter for the loess fit. Default is 0.6.                                                                                                                                         |
| xlab, ylab | optional character strings with the x- and y-axis labels. Default respectively to "Distance" and "SemiVariogram".                                                                                                                 |
| type       | an optional character indicating the type of plot. Defaults to "p".                                                                                                                                                               |
| ylim       | an optional numeric vector with the limits for the y-axis. Defaults to c(0, max(x\$variog)).                                                                                                                                      |
| grid       | an optional logical value indicating whether a grid should be added to plot. Default is FALSE.                                                                                                                                    |
| ...        | optional arguments passed to the Trellis xyplot function.                                                                                                                                                                         |

Value

an xyplot Trellis plot.

|----------|------------------------------------------|
| pooledSD | <i>Extract Pooled Standard Deviation</i> |
|----------|------------------------------------------|

---

Description

The pooled estimated standard deviation is obtained by adding together the residual sum of squares for each non-null element of object, dividing by the sum of the corresponding residual degrees-of-freedom, and taking the square-root.

**Usage**

```
pooledSD(object)
```

**Arguments**

`object` an object inheriting from class `lmList`.

**Value**

the pooled standard deviation for the non-null elements of `object`, with an attribute `df` with the number of degrees-of-freedom used in the estimation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
 weights = varPower())
newSoybean <- data.frame(Time = c(10,30,50,80,100))
predict(fm1, newSoybean)
```

---

predict.lme

*Predictions from an lme Object*

---

**Description**

The predictions at level  $i$  are obtained by adding together the population predictions (based only on the fixed effects estimates) and the estimated contributions of the random effects to the predictions at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ . If group values not included in the original grouping factors are present in newdata, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

**Usage**

```
S3 method for class 'lme'
predict(object, newdata, level = 0, asList = FALSE,
 na.action = na.fail, ...)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.                                                                                                                                                                           |
| newdata   | an optional data frame to be used for obtaining the predictions. All variables used in the fixed and random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.                                          |
| level     | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping. |
| asList    | an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of level.                                           |
| na.action | a function that indicates what should happen when newdata contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.                                                                           |
| ...       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                            |

Value

if a single level of grouping is specified in `level`, the returned value is either a list with the predictions split by groups (`asList = TRUE`) or a vector with the predictions (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

|                             |                                          |
|-----------------------------|------------------------------------------|
| <code>predict.lmList</code> | <i>Predictions from an lmList Object</i> |
|-----------------------------|------------------------------------------|

---

Description

If the grouping factor corresponding to `object` is included in `newdata`, the data frame is partitioned according to the grouping factor levels; else, `newdata` is repeated for all `lm` components. The predictions and, optionally, the standard errors for the predictions, are obtained for each `lm` component of `object`, using the corresponding element of the partitioned `newdata`, and arranged into a list with as many components as `object`, or combined into a single vector or data frame (if `se.fit=TRUE`).

Usage

```
S3 method for class 'lmList'
predict(object, newdata, subset, pool, asList, se.fit, ...)
```

Arguments

|                      |                                                                                                                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | an object inheriting from class <code>"lmList"</code> , representing a list of <code>lm</code> objects with a common model.                                                                                                     |
| <code>newdata</code> | an optional data frame to be used for obtaining the predictions. All variables used in the object model formula must be present in the data frame. If missing, the same data frame used to produce <code>object</code> is used. |
| <code>subset</code>  | an optional character or integer vector naming the <code>lm</code> components of <code>object</code> from which the predictions are to be extracted. Default is <code>NULL</code> , in which case all components are used.      |
| <code>asList</code>  | an optional logical value. If <code>TRUE</code> , the returned object is a list with the predictions split by groups; else the returned value is a vector. Defaults to <code>FALSE</code> .                                     |

|        |                                                                                                                                                              |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pool   | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> . |
| se.fit | an optional logical value indicating whether pointwise standard errors should be computed along with the predictions. Default is <code>FALSE</code> .        |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                    |

### Value

a list with components given by the predictions (and, optionally, the standard errors for the predictions) from each `lm` component of `object`, a vector with the predictions from all `lm` components of `object`, or a data frame with columns given by the predictions and their corresponding standard errors.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
predict(fm1, se.fit = TRUE)
```

---

|              |                                        |
|--------------|----------------------------------------|
| predict.nlme | <i>Predictions from an nlme Object</i> |
|--------------|----------------------------------------|

---

### Description

The predictions at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters. If group values not included in the original grouping factors are present in `newdata`, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

### Usage

```
S3 method for class 'nlme'
predict(object, newdata, level = 0, asList = FALSE,
 na.action = na.fail, naPattern = NULL, ...)
```

### Arguments

|         |                                                                                                                                                                                                                                                                      |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | an object inheriting from class <code>"nlme"</code> , representing a fitted nonlinear mixed-effects model.                                                                                                                                                           |
| newdata | an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model, the fixed and the random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned. |

|                        |                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>level</code>     | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping (and is <code>object\$dim\$Q</code> ). |
| <code>asList</code>    | an optional logical value. If TRUE and a single value is given in <code>level</code> , the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> .                                                     |
| <code>na.action</code> | a function that indicates what should happen when <code>newdata</code> contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations.                                                                                     |
| <code>naPattern</code> | an expression or formula object, specifying which returned values are to be regarded as missing.                                                                                                                                                                                                                           |
| <code>...</code>       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                  |

### Value

if a single level of grouping is specified in `level`, the returned value is either a list with the predictions split by groups (`asList = TRUE`) or a vector with the predictions (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

### Examples

```
head(Loblolly) # groupedData w/ 'Seed' is grouping variable :
Grouped Data: height ~ age | Seed
height age Seed
1 4.51 3 301
15 10.89 5 301
..

fm1 <- nlme(height ~ SSasym(age, Asym, R0, lrc), data = Loblolly,
 fixed = Asym + R0 + lrc ~ 1,
 random = Asym ~ 1, ## <---grouping---> Asym ~ 1 | Seed
 start = c(Asym = 103, R0 = -8.5, lrc = -3.3))
fm1

age. <- seq(from = 2, to = 30, by = 2)
newLL.301 <- data.frame(age = age., Seed = 301)
newLL.329 <- data.frame(age = age., Seed = 329)
(p301 <- predict(fm1, newLL.301, level = 0:1))
(p329 <- predict(fm1, newLL.329, level = 0:1))
Prediction are the same at level 0 :
all.equal(p301[, "predict.fixed"],
 p329[, "predict.fixed"])
and differ by the 'Seed' effect at level 1 :
```

```
p301[, "predict.Seed"] -
p329[, "predict.Seed"]
```

---

```
print.summary.pdMat
```

*Print a summary.pdMat Object*

---

## Description

The standard deviations and correlations associated with the positive-definite matrix represented by object (considered as a variance-covariance matrix) are printed, together with the formula and the grouping level associated object, if any are present.

## Usage

```
S3 method for class 'summary.pdMat'
print(x, sigma, rdig, Level, resid, ...)
```

## Arguments

|       |                                                                                                                                                                                                                                    |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x     | an object inheriting from class " <a href="#">summary.pdMat</a> ", generally resulting from applying <a href="#">summary</a> to an object inheriting from class " <a href="#">pdMat</a> ".                                         |
| sigma | an optional numeric value used as a multiplier for the square-root factor of the positive-definite matrix represented by object (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1. |
| rdig  | an optional integer value with the number of significant digits to be used in printing correlations. Defaults to 3.                                                                                                                |
| Level | an optional character string with a description of the grouping level associated with object (generally corresponding to levels of grouping in a mixed-effects model). Defaults to NULL.                                           |
| resid | an optional logical value. If TRUE an extra row with the "residual" standard deviation given in sigma will be included in the output. Defaults to FALSE.                                                                           |
| ...   | optional arguments passed to <code>print.default</code> ; see the documentation on that method function.                                                                                                                           |

|            |                                                   |
|------------|---------------------------------------------------|
| qqnorm.gls | <i>Normal Plot of Residuals from a gls Object</i> |
|------------|---------------------------------------------------|

---

### Description

Diagnostic plots for assessing the normality of residuals the generalized least squares fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

### Usage

```
S3 method for class 'gls'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>        | an object inheriting from class " <code>gls</code> ", representing a generalized least squares fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>form</code>     | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>y</code> can be referenced. In addition, <code>y</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> and to the left of a <code> </code> operator must evaluate to a residuals vector. Default is <code>~ resid(., type = "p")</code> , corresponding to a normal plot of the standardized residuals. |
| <code>abline</code>   | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.                                                                                                                                                                                                                                                                                                                                                          |
| <code>id</code>       | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.                                                   |
| <code>idLabels</code> | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.                                                                                                                                                                                                                                                                                     |
| <code>grid</code>     | an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xypplot</code> defaults to <code>TRUE</code> , else defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>...</code>      | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Value**

a diagnostic Trellis plot for assessing normality of residuals.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
 correlation = corAR1(form = ~ 1 | Mare))
qqnorm(fm1, abline = c(0,1))
```

qqnorm.lme

*Normal Plot of Residuals or Random Effects from an lme Object***Description**

Diagnostic plots for assessing the normality of residuals and random effects in the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

**Usage**

```
S3 method for class 'lme'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

**Arguments**

- |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>        | an object inheriting from class <code>"lme"</code> , representing a fitted linear mixed-effects model or from class <code>"lmList"</code> , representing a list of <code>lm</code> objects, or from class <code>"lm"</code> , representing a fitted linear model, or from class <code>"nls"</code> , representing a nonlinear least squares fitted model.                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>form</code>     | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>y</code> can be referenced. In addition, <code>y</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> and to the left of a <code> </code> operator must evaluate to a residuals vector, or a random effects matrix. Default is <code>~ resid(., type = "p")</code> , corresponding to a normal plot of the standardized residuals evaluated at the innermost level of nesting. |
| <code>abline</code>   | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>id</code>       | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.                                                                                                                           |
| <code>idLabels</code> | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.                                                                                                                                                                                                                                                                                                                                                             |
| <code>grid</code>     | an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>...</code>      | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Value**

a diagnostic Trellis plot for assessing normality of residuals or random effects.

**Author(s)**

Quinidine

*Quinidine Kinetics*

---

**Description**

The Quinidine data frame has 1471 rows and 14 columns.

**Format**

This data frame contains the following columns:

**Subject** a factor identifying the patient on whom the data were collected.

**time** a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.

**conc** a numeric vector giving the serum quinidine concentration (mg/L).

**dose** a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.

**interval** a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.

**Age** a numeric vector giving the age of the subject on entry to the study (yr).

**Height** a numeric vector giving the height of the subject on entry to the study (in.).

**Weight** a numeric vector giving the body weight of the subject (kg).

**Race** a factor with levels Caucasian, Latin, and Black identifying the race of the subject.

**Smoke** a factor with levels no and yes giving smoking status at the time of the measurement.

**Ethanol** a factor with levels none, current, former giving ethanol (alcohol) abuse status at the time of the measurement.

**Heart** a factor with levels No/Mild, Moderate, and Severe indicating congestive heart failure for the subject.

**Creatinine** an ordered factor with levels < 50 <>= 50 indicating the creatinine clearance (mg/min).

**glyco** a numeric vector giving the alpha-1 acid glycoprotein concentration (mg/dL). Often measured at the same time as the quinidine concentration.

## Details

Verme et al. (1992) analyze routine clinical data on patients receiving the drug quinidine as a treatment for cardiac arrhythmia (atrial fibrillation or ventricular arrhythmias). All patients were receiving oral quinidine doses. At irregular intervals blood samples were drawn and serum concentrations of quinidine were determined. These data are analyzed in several publications, including Davidian and Giltinan (1995, section 9.3).

| quinModel | <i>Model function for the Quinidine data</i> |
|-----------|----------------------------------------------|

---

## Description

A model function for a model used with the Quinidine data. This function calls compiled C code.

## Usage

```
quinModel(Subject, time, conc, dose, interval, lV, lKa, lCl)
```

## Arguments

|          |                                                                                                                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Subject  | a factor identifying the patient on whom the data were collected.                                                                                                                                                                     |
| time     | a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.                                                                     |
| conc     | a numeric vector giving the serum quinidine concentration (mg/L).                                                                                                                                                                     |
| dose     | a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base. |
| interval | a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.                                                       |
| lV       | numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time.                                                                                                                 |
| lKa      | numeric. A vector of values of the natural log of the absorption rate constant according to Subject and time.                                                                                                                         |
| lCl      | numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.                                                                                                                              |

**Details**

See the details section of [Quinidine](#) for a description of the model function that `quinModel` evaluates.

**Value**

a numeric vector of predicted quinidine concentrations.

Rail

*Evaluation of Stress in Railway Rails*

---

**Description**

The `Rail` data frame has 18 rows and 2 columns.

**Format**

This data frame contains the following columns:

**Rail** an ordered factor identifying the rail on which the measurement was made.

**travel** a numeric vector giving the travel time for ultrasonic head-waves in the rail (nanoseconds).  
The value given is the original travel time minus 36,100 nanoseconds.

**Details**

Devore (2000, Example 10.10, p. 427) cites data from an article in *Materials Evaluation* on “a study of travel time for a certain type of wave that results from longitudinal stress of rails used for railroad track.”

|                |                               |
|----------------|-------------------------------|
| random.effects | <i>Extract Random Effects</i> |
|----------------|-------------------------------|

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmList` and `lme`.

`random.effects` is an alias for `ranef`; methods are implemented for the latter.

### Usage

```
random.effects(object, ...)
ranef(object, ...)
```

### Arguments

|                     |                                                                               |
|---------------------|-------------------------------------------------------------------------------|
| <code>object</code> | any fitted model object from which random effects estimates can be extracted. |
| <code>...</code>    | some methods for this generic function require additional arguments.          |

### Value

will depend on the method function used; see the appropriate documentation.

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. pp. 100, 461.

---

|                        |                                   |
|------------------------|-----------------------------------|
| <code>ranef.lme</code> | <i>Extract lme Random Effects</i> |
|------------------------|-----------------------------------|

---

### Description

The estimated random effects at level  $i$  are represented as a data frame with rows given by the different groups at that level and columns given by the random effects. If a single level of grouping is specified, the returned object is a data frame; else, the returned object is a list of such data frames. Optionally, the returned data frame(s) may be augmented with covariates summarized over groups.

### Usage

```
S3 method for class 'lme'
ranef(object, augFrame, level, data, which, FUN,
 standard, omitGroupingFactor, subset, ...)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object             | an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| augFrame           | an optional logical value. If <code>TRUE</code> , the returned data frame is augmented with variables defined in <code>data</code> ; else, if <code>FALSE</code> , only the coefficients are returned. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| level              | an optional vector of positive integers giving the levels of grouping to be used in extracting the random effects from an object with multiple nested grouping levels. Defaults to all levels of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| data               | an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| which              | an optional positive integer vector specifying which columns of <code>data</code> should be used in the augmentation of the returned data frame. Defaults to all columns in <code>data</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| FUN                | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| standard           | an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the estimate of the standard deviation of that group of random effects). Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| omitGroupingFactor | an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| subset             | an optional expression indicating for which rows the random effects should be extracted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ...                | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Value**

a data frame, or list of data frames, with the estimated random effects at the grouping level(s) specified in `level` and, optionally, other covariates summarized over groups. The returned object inherits from classes `random.effects.lme` and `data.frame`.

**Author(s)**

|--------------|--------------------------------------|
| ranef.lmList | <i>Extract lmList Random Effects</i> |
|--------------|--------------------------------------|

---

Description

The difference between the individual lm components coefficients and their average is calculated.

Usage

```
S3 method for class 'lmList'
ranef(object, augFrame, data, which, FUN, standard,
 omitGroupingFactor, ...)
```

Arguments

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object   | an object inheriting from class " <a href="#">lmList</a> ", representing a list of lm objects with a common model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| augFrame | an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| data     | an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| which    | an optional positive integer vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| FUN      | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable. |

**standard** an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the corresponding estimated standard error). Defaults to FALSE.

**omitGroupingFactor** an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

**...** some methods for this generic require additional arguments. None are used in this method.

### Value

a vector with the differences between the individual lm coefficients in object and their average.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
ranef(fm1)
random.effects(fm1) # same as above
```

---

RatPupWeight

*The weight of rat pups*

---

### Description

The RatPupWeight data frame has 322 rows and 5 columns.

### Format

This data frame contains the following columns:

**weight** a numeric vector

**sex** a factor with levels Male Female

**Litter** an ordered factor with levels 9 < 8 < 7 < 4 < 2 < 10 < 1 < 3 < 5 < 6 < 21 < 22 < 24 < 27 < 26 < 25 < 23 < 17 < 11 < 14 < 13 < 15 < 16 < 20 < 19 < 18 < 12

**Lsize** a numeric vector

**Treatment** an ordered factor with levels Control < Low < High

---

`recalc`*Recalculate Condensed Linear Model Object*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `modelStruct`, `reStruct`, and `varFunc`.

**Usage**

```
recalc(object, conLin, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | any object which induces a recalculation of the condensed linear model object <code>conLin</code> .                                                                                                                                  |
| <code>conLin</code> | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| <code>...</code>    | some methods for this generic can take additional arguments.                                                                                                                                                                         |

**Value**

the recalculated condensed linear model object.

**Note**

This function is only used inside model fitting functions, such as `lme` and `gls`, that require recalculation of a condensed linear model object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Description

This method function pre-multiplies the "Xy" component of conLin by the transpose square-root factor(s) of the correlation matrix (matrices) associated with object and adds the log-likelihood contribution of object, given by logLik(object), to the "logLik" component of conLin.

## Usage

```
S3 method for class 'corStruct'
recalc(object, conLin, ...)
```

## Arguments

|        |                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">corStruct</a> ", representing a correlation structure.                                                                                                                                 |
| conLin | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                            |

## Value

the recalculated condensed linear model object.

## Note

This method function is only used inside model fitting functions, such as lme and gls, that allow correlated error terms.

recalc.reStruct

*Recalculate for an reStruct Object*

---

### Description

The log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by object and conLin (assuming spherical within-group covariance structure), evaluated at coef(object) is calculated and added to the logLik component of conLin. The settings attribute of object determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods for the (restricted) log-likelihood calculations are described in Bates and Pinheiro (1998).

### Usage

```
S3 method for class 'reStruct'
recalc(object, conLin, ...)
```

### Arguments

|        |                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of pdMat objects.                                                                                     |
| conLin | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                            |

### Value

the condensed linear model with its logLik component updated.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[logLik](#), [lme](#), [recalc](#), [reStruct](#)

---

recalc.varFunc

*Recalculate for varFunc Object*

---

### Description

This method function pre-multiplies the "Xy" component of conLin by a diagonal matrix with diagonal elements given by the weights corresponding to the variance structure represented by objecte and adds the log-likelihood contribution of object, given by logLik(object), to the "logLik" component of conLin.

Usage

```
S3 method for class 'varFunc'
recalc(object, conLin, ...)
```

Arguments

|        |                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class "varFunc", representing a variance function structure.                                                                                                                                               |
| conLin | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                            |

Value

the recalculated condensed linear model object.

Note

This method function is only used inside model fitting functions, such as lme and gls, that allow heteroscedastic error terms.

| Relaxin | <i>Assay for Relaxin</i> |
|---------|--------------------------|

---

Description

The Relaxin data frame has 198 rows and 3 columns.

Format

This data frame contains the following columns:

- Run** an ordered factor with levels 5 < 8 < 9 < 3 < 4 < 2 < 7 < 1 < 6
- conc** a numeric vector
- cAMP** a numeric vector

Source

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

Remifentanil

Pharmacokinetics of Remifentanil

**Description**

Intravenous infusion of remifentanil (a strong analgesic) in different rates over varying time periods was applied to a total of 65 patients. Concentration measurements of remifentanil were taken along with several covariates resulting in the Remifentanil data frame with 2107 rows and 12 columns.

**Usage**

```
Remifentanil
```

**Format**

This data frame (of class "**groupedData**", specifically "nfnGroupedData") contains the following columns:

**ID:** numerical (patient) IDs.

**Subject:** an **ordered** factor with 65 levels (of the IDs): 30 < 21 < 25 < 23 < 29 < . . . . . < 36 < 6 < 5 < 10 < 9.

**Time:** time from beginning of infusion in minutes (**numeric**).

**conc:** remifentanil concentration in [ng / ml] (**numeric**).

**Rate:** infusion rate in [µg / min].

**Amt:** amount of remifentanil given in the current time interval in [µg].

**Age:** age of the patient in years.

**Sex:** gender of the patient, a **factor** with levels Female and Male.

**Ht:** height of the patient in cm.

**Wt:** weight of the patient in kg.

**BSA:** body surface area (DuBois and DuBois 1916):  $BSA := Wt^{0.425} \cdot Ht^{0.725} \cdot 0.007184$ .

**LBM:** lean body mass (James 1976), with slightly different formula for men  $LBM_m := 1.1Wt - 128(Wt/Ht)^2$ , and women  $LBM_f := 1.07Wt - 148(Wt/Ht)^2$ .

Charles F. Minto, Thomas W. Schnider and Steven L. Shafer (1997). Pharmacokinetics and Pharmacodynamics of Remifentanil: II. Model Application. *Anesthesiology* **86** 1, 24–33. doi:10.1097/0000542199701000000005

## Examples

```
plot(Remifentanil, type = "l", lwd = 2) # shows the 65 patients' remi profiles

The same on log-log scale (*more* sensible for modeling?):
plot(Remifentanil, type = "l", lwd = 2, scales = list(log=TRUE))

str(Remifentanil)
summary(Remifentanil)

plot(xtabs(~Subject, Remifentanil))
summary(unclass(table(Remifentanil$Subject)))
between 20 and 54 measurements per patient (median: 24; mean: 32.42)

Only first measurement of each patient :
dim(Remi.1 <- Remifentanil[!duplicated(Remifentanil[, "ID"]),]) # 65 x 12

LBMfn <- function(Wt, Ht, Sex) ifelse(Sex == "Female",
 1.07 * Wt - 148*(Wt/Ht)^2,
 1.1 * Wt - 128*(Wt/Ht)^2)

with(Remi.1,
 stopifnot(all.equal(BSA, Wt^{0.425} * Ht^{0.725} * 0.007184,
 tolerance = 1.5e-5),
 all.equal(LBM, LBMfn(Wt, Ht, Sex),
 tolerance = 7e-7)
))

Rate: typically 3 µg / kg body weight, but :
sunflowerplot(Rate ~ Wt, Remifentanil)
abline(0,3, lty=2, col=adjustcolor("black", 0.5))
```

---

residuals.gls

---

*Extract gls Residuals*

---

## Description

The residuals for the linear model represented by object are extracted.

## Usage

```
S3 method for class 'gls'
residuals(object, type, ...)
```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">gls</a> ", representing a generalized least squares fitted linear model, or from class <code>gnls</code> , representing a generalized nonlinear least squares fitted linear model.                                                                                                                                                                                                                                                                                                                                |
| type   | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "response". |

... some methods for this generic function require additional arguments. None are used in this method.

### Value

a vector with the residuals for the linear model represented by object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

**Arguments**

|                     |                                                                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class " <a href="#">gnlsStruct</a> ", representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects, and attributes specifying the underlying nonlinear model and the response variable. |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                     |

**Value**

a vector with the residuals for the nonlinear model represented by `object`.

**Note**

This method function is primarily used inside `gnls` and `residuals.gnls`.

|---------------|------------------------------|
| residuals.lme | <i>Extract lme Residuals</i> |
|---------------|------------------------------|

---

## Description

The residuals at level  $i$  are obtained by subtracting the fitted levels at that level from the response vector (and dividing by the estimated within-group standard error, if `type="pearson"`). The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ .

## Usage

```
S3 method for class 'lme'
residuals(object, level = 0,
 type = c("response", "pearson", "normalized"), asList = FALSE, ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>"lme"</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>level</code>  | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population residuals. Defaults to the highest or innermost level of grouping.                                                                                                                                                                                                                                                                                                    |
| <code>type</code>   | an optional character string specifying the type of residuals to be used. If <code>"response"</code> , as by default, the “raw” residuals (observed - fitted) are used; else, if <code>"pearson"</code> , the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if <code>"normalized"</code> , the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. |
| <code>asList</code> | an optional logical value. If <code>TRUE</code> and a single value is given in <code>level</code> , the returned object is a list with the residuals split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> . Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                               |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Value

if a single level of grouping is specified in `level`, the returned value is either a list with the residuals split by groups (`asList = TRUE`) or a vector with the residuals (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the residuals at different levels and the grouping factors. For a vector or data frame result the `naresid` method is applied.

residuals(object, level, conLin, lmeFit, ...)
```

Arguments

|        |                                                                                                                                                                                                                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <a href="#">lmeStruct</a> ", representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.                                                                                                            |
| level  | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.                                  |
| conLin | an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix (X) combined with a response vector (y), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying lme model. Defaults to <code>attr(object, "conLin")</code> . |
| lmeFit | an optional list with components <code>beta</code> and <code>b</code> containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the residuals. Defaults to <code>attr(object, "lmeFit")</code> .                                                                                |
| ...    | some methods for this generic accept optional arguments.                                                                                                                                                                                                                                                                           |

Value

if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

Note

This method function is primarily used within the [lme](#) function.

**Description**

The residuals are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

**Usage**

```
S3 method for class 'lmList'
residuals(object, type, subset, asList, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class " <a href="#">lmList</a> ", representing a list of <code>lm</code> objects with a common model.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>subset</code> | an optional character or integer vector naming the <code>lm</code> components of <code>object</code> from which the residuals are to be extracted. Default is <code>NULL</code> , in which case all components are used.                                                                                                                                                                                                                                                                                                                                    |
| <code>type</code>   | an optional character string specifying the type of residuals to be extracted. Options include "response" for the "raw" residuals (observed - fitted), "pearson" for the standardized residuals (raw residuals divided by the estimated residual standard error) using different standard errors for each <code>lm</code> fit, and "pooled.pearson" for the standardized residuals using a pooled estimate of the residual standard error. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "response". |
| <code>asList</code> | an optional logical value. If <code>TRUE</code> , the returned object is a list with the residuals split by groups; else the returned value is a vector. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                   |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Value**

a list with components given by the residuals of each `lm` component of `object`, or a vector with the residuals for all `lm` components of `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lmList](#), [fitted.lmList](#)

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
residuals(fm1)
```

---

residuals.nlmeStruct    *Calculate nlmeStruct Residuals*

---

**Description**

The residuals at level  $i$  are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters.

**Usage**

```
S3 method for class 'nlmeStruct'
residuals(object, level, conLin, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class " <b>nlmeStruct</b> ", representing a list of mixed-effects model components, such as reStruct, corStruct, and varFunc objects.                                                                                                                                   |
| level  | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping. |
| conLin | an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nlme model. Defaults to attr(object, "conLin").           |
| ...    | optional arguments to the residuals generic. Not used.                                                                                                                                                                                                                                            |

**Value**

if a single level of grouping is specified in level, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in level, the returned object is a matrix with columns given by the residuals at different levels.

**Note**

This method function is primarily used within the nlme function.

reStruct

*Random Effects Structure*

---

**Description**

This function is a constructor for the `reStruct` class, representing a random effects structure and consisting of a list of `pdMat` objects, plus a `settings` attribute containing information for the optimization algorithm used to fit the associated mixed-effects model.

**Usage**

```
reStruct(object, pdClass, REML, data)
S3 method for class 'reStruct'
print(x, sigma, reEstimates, verbose, ...)
```

**Arguments**

- |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | any of the following: (i) a one-sided formula of the form $\sim x_1 + \dots + x_n \mid g_1 / \dots / g_m$ , with $x_1 + \dots + x_n$ specifying the model for the random effects and $g_1 / \dots / g_m$ the grouping structure ( $m$ may be equal to 1, in which case no $/$ is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form $\sim x_1 + \dots + x_n \mid g$ , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form $\sim x_1 + \dots + x_n$ , or a <code>pdMat</code> object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or <code>pdMat</code> objects. In this case, the grouping structure formula will be derived from the data used to fit the mixed-effects model, which should inherit from class <code>groupedData</code> ; (iv) a named list of formulas or <code>pdMat</code> objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an <code>reStruct</code> object. |
| pdClass | an optional character string with the name of the <code>pdMat</code> class to be used for the formulas in <code>object</code> . Defaults to <code>"pdLogChol"</code> which corresponds to a general positive-definite matrix (Log-Cholesky parametrization).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| REML    | an optional logical value. If <code>TRUE</code> , the associated mixed-effects model will be fitted using restricted maximum likelihood; else, if <code>FALSE</code> , maximum likelihood will be used. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| data    | an optional data frame in which to evaluate the variables used in the random effects formulas in <code>object</code> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying <code>pdMat</code> objects. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| x       | an object inheriting from class <code>reStruct</code> to be printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| sigma   | an optional numeric value used as a multiplier for the square-root factors of the <code>pdMat</code> components (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|             |                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------|
| reEstimates | an optional list with the random effects estimates for each level of grouping. Only used when verbose = TRUE. |
| verbose     | an optional logical value determining if the random effects estimates should be printed. Defaults to FALSE.   |
| ...         | Optional arguments can be given to other methods for this generic. None are used in this method.              |

Value

an object inheriting from class reStruct, representing a random effects structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

Examples

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
rs1 # 2 entries "Uninitialized"
str(rs1) # a bit more
```

---

|              |                                         |
|--------------|-----------------------------------------|
| simulate.lme | <i>Simulate Results from lme Models</i> |
|--------------|-----------------------------------------|

---

Description

The model object is fit to the data. Using the fitted values of the parameters, nsim new data vectors from this model are simulated. Both object and m2 are fit by maximum likelihood (ML) and/or by restricted maximum likelihood (REML) to each of the simulated data vectors.

Usage

```
S3 method for class 'lme'
simulate(object, nsim = 1, seed = , m2,
 method = c("REML", "ML"), niterEM = c(40, 200), useGen, ...)
```

Arguments

|        |                                                                                                                                                                                                                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class "lme", representing a fitted linear mixed-effects model, or a list containing an lme model specification. If given as a list, it should contain components fixed, data, and random with values suitable for a call to lme. This argument defines the null model. |
| m2     | an "lme" object or a list, like object containing a second lme model specification. This argument defines the alternative model. If given as a list, only those parts of the specification that change between model object and m2 need to be specified.                                         |
| seed   | an optional integer that is passed to set.seed. Defaults to a random integer.                                                                                                                                                                                                                    |

|         |                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| method  | an optional character array. If it includes "REML" the models are fit by maximizing the restricted log-likelihood. If it includes "ML" the log-likelihood is maximized. Defaults to c("REML", "ML"), in which case both methods are used.                                                                                                                                                             |
| nsim    | an optional positive integer specifying the number of simulations to perform. Defaults to 1. <b>This has changed. Previously the default was 1000.</b>                                                                                                                                                                                                                                                |
| niterEM | an optional integer vector of length 2 giving the number of iterations of the EM algorithm to apply when fitting the object and m2 to each simulated set of data. Defaults to c(40, 200).                                                                                                                                                                                                             |
| useGen  | an optional logical value. If TRUE, the <a href="#">nlminb</a> optimizer is used with numerical derivatives of the log-likelihood. If FALSE, the <a href="#">nlm</a> algorithm is used with an analytic gradient. The default depends on the "pdMat" classes used in object and m2: if both are standard classes (see <a href="#">pdClasses</a> ) then defaults to FALSE, otherwise defaults to TRUE. |
| ...     | optional additional arguments. None are used.                                                                                                                                                                                                                                                                                                                                                         |

### Value

an object of class `simulate.lme` with components `null` and `alt`. Each of these has components ML and/or REML which are matrices. An attribute called `seed` contains the seed that was used for the random number generator.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

### Examples

```
orthSim <-
 simulate.lme(list(fixed = distance ~ age, data = Orthodont,
 random = ~ 1 | Subject),
 nsim = 3, # limited here for speed
 m2 = list(random = ~ age | Subject))
```

---

solve.pdMat

*Calculate Inverse of a Positive-Definite Matrix*

---

### Description

The positive-definite matrix represented by `a` is inverted and assigned to `a`.

### Usage

```
S3 method for class 'pdMat'
solve(a, b, ...)
```

**Arguments**

- a an object inheriting from class "[pdMat](#)", representing a positive definite matrix.
- b this argument is only included for consistency with the generic function and is not used in this method function.
- ... some methods for this generic require additional arguments. None are used in this method.

**Value**

a `pdMat` object similar to `a`, but with coefficients corresponding to the inverse of the positive-definite matrix represented by `a`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[pdMat](#)

**Examples**

```
pd1 <- pdCompSymm(3 * diag(3) + 1)
solve(pd1)
```

---

`solve.reStruct`

*Apply Solve to an reStruct Object*

---

**Description**

Solve is applied to each `pdMat` component of `a`, which results in inverting the positive-definite matrices they represent.

**Usage**

```
S3 method for class 'reStruct'
solve(a, b, ...)
```

**Arguments**

- a an object inheriting from class "[reStruct](#)", representing a random effects structure and consisting of a list of `pdMat` objects.
- b this argument is only included for consistency with the generic function and is not used in this method function.
- ... some methods for this generic require additional arguments. None are used in this method.

**Value**

an `reStruct` object similar to `a`, but with the `pdMat` components representing the inverses of the matrices represented by the components of `a`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
 B = pdDiag(2 * diag(4), form = ~Educ)))
solve(rs1)
```

---

Soybean

*Growth of soybean plants*

---

**Description**

The Soybean data frame has 412 rows and 5 columns.

**Format**

This data frame contains the following columns:

**Plot** a factor giving a unique identifier for each plot.

**Variety** a factor indicating the variety; Forrest (F) or Plant Introduction #416937 (P).

**Year** a factor indicating the year the plot was planted.

**Time** a numeric vector giving the time the sample was taken (days after planting).

**weight** a numeric vector giving the average leaf weight per plant (g).

**Details**

These data are described in Davidian and Giltinan (1995, 1.1.3, p.7) as “Data from an experiment to compare growth patterns of two genotypes of soybeans: Plant Introduction #416937 (P), an experimental strain, and Forrest (F), a commercial variety.”

Davidian, M. and Giltinan, D. M. (1995), *Nonlinear Models for Repeated Measurement Data*, Chapman and Hall, London.

**Examples**

```
summary(fm1 <- nlsList(SSlogis, data = Soybean))
```

---

splitFormula

*Split a Formula*

---

### Description

Splits the right hand side of `form` into a list of subformulas according to the presence of `sep`. The left hand side of `form`, if present, will be ignored. The length of the returned list will be equal to the number of occurrences of `sep` in `form` plus one.

### Usage

```
splitFormula(form, sep)
```

### Arguments

|                   |                                                                                                                              |
|-------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>form</code> | a formula object.                                                                                                            |
| <code>sep</code>  | an optional character string specifying the separator to be used for splitting the formula. Defaults to <code>" / "</code> . |

### Value

a list of formulas, corresponding to the split of `form` according to `sep`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

### Examples

```
splitFormula(~ g1/g2/g3)
```

---

Spruce

*Growth of Spruce Trees*

---

### Description

The Spruce data frame has 1027 rows and 4 columns.

### Format

This data frame contains the following columns:

**Tree** a factor giving a unique identifier for each tree.

**days** a numeric vector giving the number of days since the beginning of the experiment.

**logSize** a numeric vector giving the logarithm of an estimate of the volume of the tree trunk.

**plot** a factor identifying the plot in which the tree was grown.

## Details

Diggle, Liang, and Zeger (1994, Example 1.3, page 5) describe data on the growth of spruce trees that have been exposed to an ozone-rich atmosphere or to a normal atmosphere.

|                   |                                     |
|-------------------|-------------------------------------|
| summary.corStruct | <i>Summarize a corStruct Object</i> |
|-------------------|-------------------------------------|

---

## Description

This method function prepares object to be printed using the `print.summary` method, by changing its class and adding a `structName` attribute to it.

## Usage

```
S3 method for class 'corStruct'
summary(object, structName, ...)
```

## Arguments

|                         |                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>     | an object inheriting from class " <code>corStruct</code> ", representing a correlation structure.                                                                                                              |
| <code>structName</code> | an optional character string defining the type of correlation structure associated with <code>object</code> , to be used in the <code>print.summary</code> method. Defaults to <code>class(object)[1]</code> . |
| <code>...</code>        | some methods for this generic require additional arguments. None are used in this method.                                                                                                                      |

## Value

an object identical to `object`, but with its class changed to `summary.corStruct` and an additional attribute `structName`. The returned value inherits from the same classes as `object`.

## Author(s)

José Pinheiro and Douglas Bates

cs1 <- corAR1(0.2)
summary(cs1)
```

summary.gls

*Summarize a Generalized Least Squares gls Object***Description**

Additional information about the linear model fit represented by object is extracted and included as components of object.

**Usage**

```
S3 method for class 'gls'
summary(object, verbose, ...)
```

**Arguments**

|         |                                                                                                                        |
|---------|------------------------------------------------------------------------------------------------------------------------|
| object  | an object inheriting from class " <a href="#">gls</a> ", representing a generalized least squares fitted linear model. |
| verbose | an optional logical value used to control the amount of output when the object is printed. Defaults to FALSE.          |
| ...     | some methods for this generic require additional arguments. None are used in this method.                              |

**Value**

an object inheriting from class `summary.gls` with all components included in object (see [glsObject](#) for a full description of the components) plus the following components:

|           |                                                                                                                                                                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| corBeta   | approximate correlation matrix for the coefficients estimates                                                                                                                                                                                                                                                                |
| tTable    | a matrix with columns Value, Std. Error, t-value, and p-value representing respectively the coefficients estimates, their approximate standard errors, the ratios between the estimates and their standard errors, and the associated p-value under a <i>t</i> approximation. Rows correspond to the different coefficients. |
| residuals | if more than five observations are used in the <code>gls</code> fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the residuals distribution; else the residuals.                                                                                                                       |
| AIC       | the Akaike Information Criterion corresponding to object.                                                                                                                                                                                                                                                                    |
| BIC       | the Bayesian Information Criterion corresponding to object.                                                                                                                                                                                                                                                                  |

|-------------|--------------------------------|
| summary.lme | <i>Summarize an lme Object</i> |
|-------------|--------------------------------|

---

## Description

Additional information about the linear mixed-effects fit represented by object is extracted and included as components of object. The returned object has a [print](#) and a [coef](#) method, the latter returning the coefficient's `tTable`.

## Usage

```
S3 method for class 'lme'
summary(object, adjustSigma, verbose, ...)
S3 method for class 'summary.lme'
print(x, verbose = FALSE, ...)
```

## Arguments

|             |                                                                                                                                                                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object      | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.                                                                                                                                                                                                                               |
| adjustSigma | an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE. |
| verbose     | an optional logical value used to control the amount of output in the <code>print.summary.lme</code> method. Defaults to FALSE.                                                                                                                                                                                                          |
| ...         | additional optional arguments passed to methods, mainly for the <a href="#">print</a> method.                                                                                                                                                                                                                                            |
| x           | a " <code>summary.lme</code> " object.                                                                                                                                                                                                                                                                                                   |

## Value

an object inheriting from class `summary.lme` with all components included in object (see [lmeObject](#) for a full description of the components) plus the following components:

|                        |                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>corFixed</code>  | approximate correlation matrix for the fixed effects estimates.                                                                                                                                                                                                                                                                                                     |
| <code>tTable</code>    | a matrix with columns named Value, Std. Error, DF, t-value, and p-value representing respectively the fixed effects estimates, their approximate standard errors, the denominator degrees of freedom, the ratios between the estimates and their standard errors, and the associated p-value from a t distribution. Rows correspond to the different fixed effects. |
| <code>residuals</code> | if more than five observations are used in the <code>lme</code> fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the innermost grouping level residuals distribution; else the innermost grouping level residuals.                                                                                                            |
| <code>AIC</code>       | the Akaike Information Criterion corresponding to object.                                                                                                                                                                                                                                                                                                           |
| <code>BIC</code>       | the Bayesian Information Criterion corresponding to object.                                                                                                                                                                                                                                                                                                         |

|                |                                   |
|----------------|-----------------------------------|
| summary.lmList | <i>Summarize an lmList Object</i> |
|----------------|-----------------------------------|

---

Description

The `summary.lm` method is applied to each `lm` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.lmList` method.

Usage

```
S3 method for class 'lmList'
summary(object, pool, ...)
```

Arguments

|                     |                                                                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>"lmList"</code> , representing a list of <code>lm</code> fitted objects.                                               |
| <code>pool</code>   | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> . |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                    |

Value

a list with summary statistics obtained by applying `summary.lm` to the elements of `object`, inheriting from class `summary.lmList`. The components of value are:

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>call</code>         | a list containing an image of the <code>lmList</code> call that produced <code>object</code> .                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>coefficients</code> | a three dimensional array with summary information on the <code>lm</code> coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by <code>"Value"</code> , <code>"Std. Error"</code> , <code>"t value"</code> , and <code>"Pr(&gt; t )"</code> , corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names. |
| <code>correlation</code>  | a three dimensional array with the correlations between the individual <code>lm</code> coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by <code>lm</code> component.                                                                             |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cov.unscaled | a three dimensional array with the unscaled variances/covariances for the individual <code>lm</code> coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by <code>lm</code> component. |
| df           | an array with the number of degrees of freedom for the model and for residuals, for each <code>lm</code> component.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| df.residual  | the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all <code>lm</code> components.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| fstatistics  | an array with the F test statistics and corresponding degrees of freedom, for each <code>lm</code> component.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| pool         | the value of the <code>pool</code> argument to the function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| r.squared    | a vector with the multiple R-squared statistics for each <code>lm</code> component.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| residuals    | a list with components given by the residuals from individual <code>lm</code> fits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| RSE          | the pooled estimate of the residual standard error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| sigma        | a vector with the residual standard error estimates for the individual <code>lm</code> fits.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| terms        | the terms object used in fitting the individual <code>lm</code> components.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|---------------------|---------------------------------------|
| summary.modelStruct | <i>Summarize a modelStruct Object</i> |
|---------------------|---------------------------------------|

---

**Description**

This method function applies `summary` to each element of object.

**Usage**

```
S3 method for class 'modelStruct'
summary(object, ...)
```

**Arguments**

|        |                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class "modelStruct", representing a list of model components, such as <code>reStruct</code> , <code>corStruct</code> and <code>varFunc</code> objects. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                        |

Value

a list with elements given by the summarized components of object. The returned value is of class summary.modelStruct, also inheriting from the same classes as object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|-----------------|------------------------------------|
| summary.nlsList | <i>Summarize an nlsList Object</i> |
|-----------------|------------------------------------|

---

Description

The summary function is applied to each nls component of object to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the print.summary.nlsList method.

Usage

```
S3 method for class 'nlsList'
summary(object, ...)
```

Arguments

- object      an object inheriting from class "[nlsList](#)", representing a list of nls fitted objects.
- ...        optional arguments to the summary.lmList method. One such optional argument is pool, a logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool").

Value

a list with summary statistics obtained by applying summary to the elements of object, inheriting from class summary.nlsList. The components of value are:

- call        a list containing an image of the nlsList call that produced object.
- parameters    a three dimensional array with summary information on the nls coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(>|t|)", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| correlation  | a three dimensional array with the correlations between the individual nls coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by nls component.                                                                                                                                        |
| cov.unscaled | a three dimensional array with the unscaled variances/covariances for the individual lm coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by nls component. |
| df           | an array with the number of degrees of freedom for the model and for residuals, for each nls component.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| df.residual  | the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all nls components.                                                                                                                                                                                                                                                                                                                                                                                                           |
| pool         | the value of the pool argument to the function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| RSE          | the pooled estimate of the residual standard error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| sigma        | a vector with the residual standard error estimates for the individual lm fits.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

---

summary.pdMat

---

*Summarize a pdMat Object*

---

**Description**

Attributes structName and noCorrelation, with the values of the corresponding arguments to the method function, are appended to object and its class is changed to summary.pdMat.

**Usage**

```
S3 method for class 'pdMat'
summary(object, structName, noCorrelation, ...)
```

Arguments

- object            an object inheriting from class "[pdMat](#)", representing a positive definite matrix.
- structName       an optional character string with a description of the pdMat class. Default depends on the method function: "Blocked" for pdBlocked, "Compound Symmetry" for pdCompSymm, "Diagonal" for pdDiag, "Multiple of an Identity" for pdIdent, "General Positive-Definite, Natural Parametrization" for pdNatural, "General Positive-Definite" for pdSymm, and data.class(object) for pdMat.
- noCorrelation    an optional logical value indicating whether correlations are to be printed in print.summary.pdMat. Default depends on the method function: FALSE for pdDiag and pdIdent, and TRUE for all other classes.
- ...               some methods for this generic require additional arguments. None are used in this method.

Value

an object similar to object, with additional attributes structName and noCorrelation, inheriting from class summary.pdMat.

update.modelStruct

*Update a modelStruct Object*

---

**Description**

This method function updates each element of object, allowing the access to data.

**Usage**

```
S3 method for class 'modelStruct'
update(object, data, ...)
```

**Arguments**

|        |                                                                                                                                |
|--------|--------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects. |
| data   | a data frame in which to evaluate the variables needed for updating the elements of object.                                    |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                      |

**Value**

an object similar to object (same class, length, and names), but with updated elements.

**Note**

This method function is primarily used within model fitting functions, such as `lme` and `gls`, that allow model components such as variance functions.

|----------------|------------------------------|
| update.varFunc | <i>Update varFunc Object</i> |
|----------------|------------------------------|

---

**Description**

If the `formula(object)` includes a "." term, representing a fitted object, the variance covariate needs to be updated upon completion of an optimization cycle (in which the variance function weights are kept fixed). This method function allows a reevaluation of the variance covariate using the current fitted object and, optionally, other variables in the original data.

**Usage**

```
S3 method for class 'varFunc'
update(object, data, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class " <a href="#">varFunc</a> ", representing a variance function structure.                                                                                                                                |
| <code>data</code>   | a list with a component named "." with the current version of the fitted object (from which fitted values, coefficients, and residuals can be extracted) and, if necessary, other variables used to evaluate the variance covariate(s). |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                               |

**Value**

if `formula(object)` includes a "." term, an `varFunc` object similar to `object`, but with the variance covariate reevaluated at the current fitted object value; else `object` is returned unchanged.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|------------|----------------------------------|
| varClasses | <i>Variance Function Classes</i> |
|------------|----------------------------------|

---

**Description**

Standard classes of variance function structures (varFunc) available in the **nlme** package. Covariates included in the variance function, denoted by variance covariates, may involve functions of the fitted model object, such as the fitted values and the residuals. Different coefficients may be assigned to the levels of a classification factor.

**Value**

Available standard classes:

|               |                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------|
| varExp        | exponential of a variance covariate.                                                                                  |
| varPower      | power of a variance covariate.                                                                                        |
| varConstPower | constant plus power of a variance covariate.                                                                          |
| varConstProp  | constant plus proportion of a variance covariate.                                                                     |
| varIdent      | constant variance(s), generally used to allow different variances according to the levels of a classification factor. |
| varFixed      | fixed weights, determined by a variance covariate.                                                                    |
| varComb       | combination of variance functions.                                                                                    |

**Note**

Users may define their own varFunc classes by specifying a constructor function and, at a minimum, methods for the functions [coef](#), [coef<-](#), and [Initialize](#). For examples of these functions, see the methods for class varPower.

varComb

*Combination of Variance Functions***Description**

This function is a constructor for the varComb class, representing a combination of variance functions. The corresponding variance function is equal to the product of the variance functions of the varFunc objects listed in . . .

**Usage**

```
varComb(...)
```

**Arguments**

. . . objects inheriting from class varFunc representing variance function structures.

**Value**

a varComb object representing a combination of variance functions, also inheriting from class varFunc.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**Examples**

```
vf1 <- varComb(varIdent(form = ~1|Sex), varPower())
```

varConstPower

*Constant Plus Power Variance Function***Description**

This function is a constructor for the varConstPower class, representing a constant plus power variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the constant plus power variance function is defined as  $\sigma^2(v) = (\theta_1 + |v|_2^{\theta_2})^2$ , where  $\theta_1, \theta_2$  are the variance function coefficients. When a grouping factor is present, different  $\theta_1, \theta_2$  are used for each factor level.

**Usage**

```
varConstPower(const, power, form, fixed)
```

**Arguments**

- |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| const, power | optional numeric vectors, or lists of numeric values, with, respectively, the coefficients for the constant and the power terms. Both arguments must have length one, unless a grouping factor is specified in form. If either argument has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in form. If a grouping factor is present in form and the argument has length one, its value will be assigned to all grouping levels. Only positive values are allowed for const. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).                                                                                                                                                                                                                                                                                                                                                           |
| form         | an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate <code>v</code> and, optionally, a grouping factor <code>g</code> for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using <code>"."</code> , representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in form, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, as in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to <code>~ fitted(.)</code> representing a variance covariate given by the fitted values of a fitted model object and no grouping factor. |
| fixed        | an optional list with components <code>const</code> and/or <code>power</code> , consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in form, the components of <code>fixed</code> must have names identifying which coefficients are to be fixed. Coefficients included in <code>fixed</code> are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Value**

a `varConstPower` object representing a constant plus power variance function structure, also inheriting from class `varFunc`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
vf1 <- varConstPower(1.2, 0.2, form = ~age|Sex)
```

---

varConstProp

*Constant Plus Proportion Variance Function*

---

## Description

This function is a constructor for the `varConstProp` class, representing a variance function structure corresponding to a two-component error model (additive and proportional error). Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the two-component variance function is defined as  $\sigma^2(v) = a^2 + b^2 * v^2$ , where  $a$  is the additive component and  $b$  is the relative error component. In order to avoid overparameterisation of the model, it is recommended to use the possibility to fix sigma, preferably to a value of 1 (see examples).

## Usage

```
varConstProp(const, prop, form, fixed)
```

## Arguments

- |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| const, prop | optional numeric vectors, or lists of numeric values, with, respectively, the coefficients for the constant and the proportional error terms. Both arguments must have length one, unless a grouping factor is specified in <code>form</code> . If either argument has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in <code>form</code> . If a grouping factor is present in <code>form</code> and the argument has length one, its value will be assigned to all grouping levels. Only positive values are allowed for <code>const</code> . Default is 0.1 for both <code>const</code> and <code>prop</code> .                                                                                                                                                                                                                                                                                                                                                                                                                           |
| form        | an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate $v$ and, optionally, a grouping factor $g$ for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using <code>"."</code> , representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, as in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to <code>~ fitted(.)</code> representing a variance covariate given by the fitted values of a fitted model object and no grouping factor. |
| fixed       | an optional list with components <code>const</code> and/or <code>power</code> , consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in <code>form</code> , the components of <code>fixed</code> must have names identifying which coefficients are to be fixed. Coefficients included in <code>fixed</code> are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Value**

a varConstProp object representing a constant plus proportion variance function structure, also inheriting from class varFunc.

**Note**

The error model underlying this variance function structure can be understood to result from two uncorrelated sequences of standardized random variables (Lavielle(2015), p. 55) and has been proposed for use in analytical chemistry (Werner et al. (1978), Wilson et al. (2004)) and chemical degradation kinetics (Ranke and Meinecke (2019)). Note that the two-component error model proposed by Rocke and Lorenzato (1995) assumed a log-normal distribution of residuals at high absolute values, which is not compatible with the `varFunc` structures in package `nlme`.

VarCorr

---

*Extract variance and correlation components*

---

## Description

This function calculates the estimated variances, standard deviations, and correlations between the random-effects terms in a linear mixed-effects model, of class "**lme**", or a nonlinear mixed-effects model, of class "**nlme**". The within-group error variance and standard deviation are also calculated.

## Usage

```

VarCorr(x, sigma = 1, ...)
S3 method for class 'lme'
VarCorr(x, sigma = x$sigma, rdig = 3, ...)

S3 method for class 'pdMat'
VarCorr(x, sigma = 1, rdig = 3, ...)

```

```
S3 method for class 'pdBlocked'
VarCorr(x, sigma = 1, rdig = 3, ...)
```

### Arguments

|       |                                                                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| x     | a fitted model object, usually an object inheriting from class " <a href="#">lme</a> ".                                                          |
| sigma | an optional numeric value used as a multiplier for the standard deviations. The default is x\$sigma or 1 depending on <a href="#">class</a> (x). |
| rdig  | an optional integer value specifying the number of digits used to represent correlation estimates. Default is 3.                                 |
| ...   | further optional arguments passed to other methods (none for the methods documented here).                                                       |

### Value

a matrix with the estimated variances, standard deviations, and correlations for the random effects. The first two columns, named Variance and StdDev, give, respectively, the variance and the standard deviations. If there are correlation components in the random effects model, the third column, named Corr, and the remaining unnamed columns give the estimated correlations among random effects within the same level of grouping. The within-group error variance and standard deviation are included as the last row in the matrix.

fm1 <- lme(distance ~ age, data = Orthodont, random = ~age)
VarCorr(fm1)
```

---

varExp

---

*Exponential Variance Function*

---

### Description

This function is a constructor for the varExp class, representing an exponential variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the exponential variance function is defined as  $\sigma^2(v) = \exp(2\theta v)$ , where  $\theta$  is the variance function coefficient. When a grouping factor is present, a different  $\theta$  is used for each factor level.

**Usage**

```
varExp(value, form, fixed)
```

**Arguments**

- |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in form. If value has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in form. If a grouping factor is present in form and value has length one, its value will be assigned to all grouping levels. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| form  | an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate <code>v</code> and, optionally, a grouping factor <code>g</code> for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using <code>"."</code> , representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in form, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to <code>~ fitted(.)</code> representing a variance covariate given by the fitted values of a fitted model object and no grouping factor. |
| fixed | an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in form, fixed must have names identifying which coefficients are to be fixed. Coefficients included in fixed are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Value**

a `varExp` object representing an exponential variance function structure, also inheriting from class `varFunc`.

**Author(s)**

**Examples**

```
vf1 <- varExp(0.2, form = ~age|Sex)
```

---

`varFixed`*Fixed Variance Function*

---

**Description**

This function is a constructor for the `varFixed` class, representing a variance function with fixed variances. Letting  $v$  denote the variance covariate defined in `value`, the variance function  $\sigma^2(v)$  for this class is  $\sigma^2(v) = |v|$ . The variance covariate  $v$  is evaluated once at initialization and remains fixed thereafter. No coefficients are required to represent this variance function.

**Usage**

```
varFixed(value)
```

**Arguments**

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <code>value</code> | a one-sided formula of the form $\sim v$ specifying a variance covariate $v$ . Grouping factors are ignored. |
|--------------------|--------------------------------------------------------------------------------------------------------------|

**Value**

a `varFixed` object representing a fixed variance function structure, also inheriting from class `varFunc`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
vf1 <- varFixed(~age)
```

---

|         |                                    |
|---------|------------------------------------|
| varFunc | <i>Variance Function Structure</i> |
|---------|------------------------------------|

---

**Description**

If object is a one-sided formula, it is used as the argument to [varFixed](#) and the resulting object is returned. Else, if object already inherits from class "varFunc", such as all standard '[varClasses](#)', it is returned unchanged.

**Usage**

```
varFunc(object)
```

**Arguments**

|        |                                                                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | either an one-sided formula specifying a variance covariate, or an object inheriting from class "varFunc", representing a variance function structure. |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------|

**Value**

an object from class "varFunc", representing a variance function structure.

|----------|-----------------------------------|
| varIdent | <i>Constant Variance Function</i> |
|----------|-----------------------------------|

---

**Description**

This function is a constructor for the varIdent class, representing a constant variance function structure. If no grouping factor is present in form, the variance function is constant and equal to one, and no coefficients required to represent it. When form includes a grouping factor with  $M > 1$  levels, the variance function allows M different variances, one for each level of the factor. For identifiability reasons, the coefficients of the variance function represent the ratios between the variances and a reference variance (corresponding to a reference group level). Therefore, only  $M - 1$  coefficients are needed to represent the variance function. By default, if the elements in value are unnamed, the first group level is taken as the reference level.

**Usage**

```
varIdent(value, form, fixed)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | an optional numeric vector, or list of numeric values, with the variance function coefficients. If no grouping factor is present in form, this argument is ignored, as the resulting variance function contains no coefficients. If value has length one, its value is repeated for all coefficients in the variance function. If value has length greater than one, it must have length equal to the number of grouping levels minus one and names which identify its elements to the levels of the grouping factor. Only positive values are allowed for this argument. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one). |
| form  | an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate <code>v</code> and, optionally, a grouping factor <code>g</code> for the coefficients. The variance covariate is ignored in this variance function. When a grouping factor is present in form, a different coefficient value is used for each of its levels less one reference level. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to <code>~ 1</code> .                                                           |
| fixed | an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. It must have names identifying which coefficients are to be fixed. Coefficients included in fixed are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.                                                                                                                                                                                                                                                                                                                                                                      |

Variogram

---

*Calculate Semi-variogram*

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include "gls" and "lme"; there is also a default method for arbitrary vectors (of residuals). See the appropriate method documentation for a description of the arguments.

## Usage

```
Variogram(object, distance, ...)
```

## Arguments

|          |                                                                                                                                                                                                                                                                  |
